In media containing strontium or barium ions, as in normal Locke solution, tetrodotoxin (10^{-5} g/ml.) had no inhibitory effect on the spikes, but the transition metal ions retained their suppressive effect on the spikes. The excitation mechanism in a calcium free medium containing strontium or barium seemed therefore to be essentially the same as that in normal Locke solution.

Acetylcholine (10^{-6} g/ml.), which in normal conditions invariably induces depolarization, increase in spike frequency and contraction, had surprisingly little effect on membrane potential and tension when calcium ions were substituted by strontium ions (Fig. 2). Similar results were observed with histamine (10^{-6} g/ml.) and angiotensin (10^{-7} g/ml.), and even ten to one hundred times the usual concentrations of these drugs had very little effect. The loss of the effect was reversed in proportion to the amount of calcium ions that was restored to the medium. The effect of these substances on potassium depolarized taenia coli also became negligible when the external calcium ions were replaced by an equivalent amount of strontium ions, and completely disappeared in a solution in which barium ions replaced calcium ions. The inability of the ileum of guinea-pig to respond to acetylcholine in a medium containing strontium ions is also suggested by the data given by Johnson during his study of the release of acetylcholine from nerve endings[10].

In the absence of calcium ions, noradrenaline (10^{-6} g/ml.), adrenaline (10^{-6} g/ml.) and isoprenaline (10^{-7} g/ml.) lost

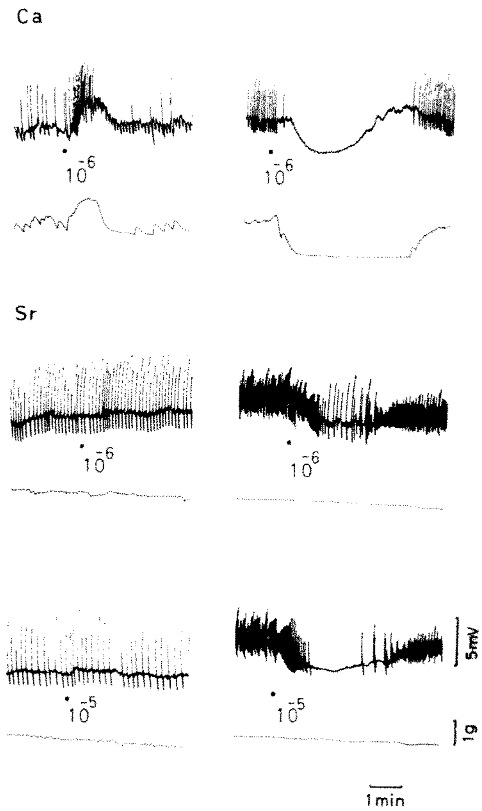

Fig. 2. Sucrose-gap records showing the effect of acetylcholine (left) and adrenaline (right) on the taenia coli of the guinea-pig. The dots indicate the time of drug applications for 30 s. The upper records show the effect of acetylcholine (10^{-6} g/ml.) and adrenaline (10^{-6} g/ml.) in normal Locke solution. The middle records show the ineffectiveness of both drugs after exposure for 20 min to calcium-free solution containing 1·8 mM strontium. The lower records were taken after an interval of 6 min, when both drugs were applied in a concentration of 10^{-5} g/ml. in solution containing strontium.

their ability both to hyperpolarize the membrane and to inhibit the spontaneous discharge of "barium ion-spikes". The effect of these catecholamines often remained in a solution containing strontium (Fig. 2), but if the tissue was washed by calcium ion-free Locke solution containing 1 mM GEDTA for several minutes beforehand, the effect almost disappeared in media containing strontium ions. Schild has recently demonstrated the special role of calcium in the relaxation of the depolarized rat uterus induced by isoprenaline[11].

The ineffectiveness of the drugs after the substitution of strontium or barium ions for calcium ions is the result not of depolarization nor of the presence of high frequency discharge for the following reasons: (1) the results are essentially the same even if the membrane potential is maintained at its normal value by increasing the concentration of strontium or barium ions to 7·2 or 18 mM; (2) the spike frequency is initially high in media containing strontium or barium ions, but it gradually declines to less than normal in an hour. In spite of this slowing, the ineffectiveness of drugs remains unchanged throughout the experiment.

These results suggest that calcium ions, as the charge carrier during the action potential in the taenia coli of the guinea-pig, can be replaced by other alkaline-earth metal ions, although strontium and barium ions have a weaker stabilizing action than calcium ions, and that barium and strontium ions are weak substitutes for calcium ions in triggering contraction. Calcium ions seem to play an essential part in the actions of certain drugs. Various normally excitatory or inhibitory drugs have little effect when calcium ions are replaced by other alkaline-earth metal ions, even though a normal excitation mechanism is maintained.

We thank Professor S. Ebashi, Dr M. Endo and Dr Y. Nonomura for their advice and discussion. This work was supported in part by a grant from the Pharmacological Research Foundation, Tokyo.

Amphetamine Anorexia by Direct Action on the Adrenergic Feeding System of Rat Hypothalamus

It has been suggested that amphetamine causes loss of appetite by direct chemical interaction with the hypothalamic feeding system. This is based on the observation that intraperitoneally injected amphetamine is less effective in depressing food intake in rats when they have lateral hypothalamic lesions and have recovered from the post-operative aphagia[1]. Such evidence is not conclusive, however, because of the possibility that anorexia arises from the action of amphetamine on a part of the system which is necessary to feeding in the normal rat, but which is not necessary to the elicitation of eating by food deprivation in rats which have overcome the aphagia resulting from the lesions. Amphetamine raises the current threshold for elicitation of eating by electrical stimulation of the lateral hypothalamus[2,3]; this indicates, also indirectly, that it acts there or on efferent systems. Determination of the behavioural effect of administering amphetamine directly into the lateral hypothalamus is a necessary part of establishing the suggestion that anorexia arises primarily from its action there.

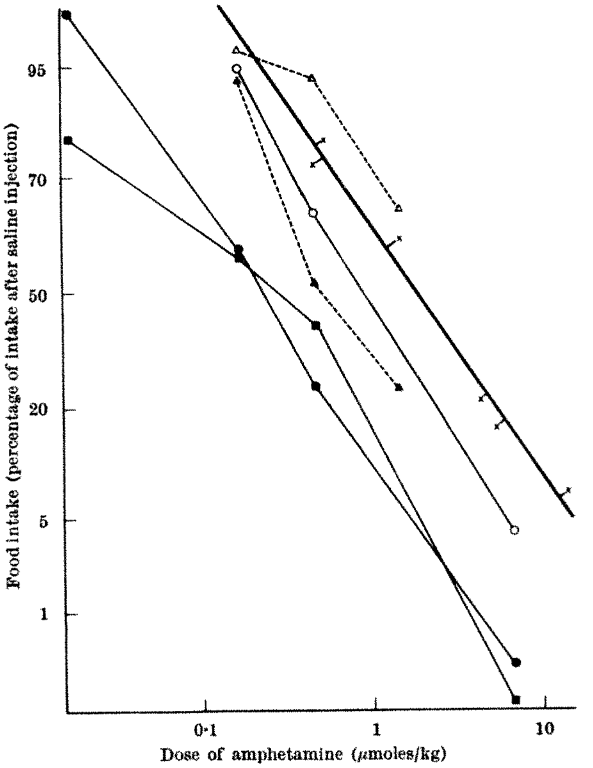

Fig. 1. Dose–response relationships for depression of food intake over 90 min after 6 h of food deprivation and injection of amphetamine by various routes. ×, Intraperitoneal injection ($N = 40$); solid symbols: "eaters" to noradrenaline; open symbols: "non-eaters"; ■, preoptic cannulae (2); ●, anterior hypothalamic cannulae (2); ○, posterior hypothalamus or diagonal band; ▲, △, anterior hypothalamic cannulae with surrounding lesion.

It has been stated that crystalline amphetamine placed in the lateral hypothalamus does not affect food intake[3]. Unilateral injection of 0·6 μl. of 65 mM *d*-amphetamine into the anterior lateral hypothalamic area does not elicit feeding in satiated rats[4]. Our data show, however, that both bilateral (Fig. 1) and unilateral (Table 1) injections of solutions of amphetamine into the lateral hypothalamic area depress food intake in deprived rats.

Various concentrations of *d*-amphetamine hydrochloride, made isotonic with sodium chloride, were injected in a volume of 1 μl. into the left side of the hypothalamus of 300–400 g Sprague–Dawley albino rats after 6 h of food deprivation. Each concentration was given twice. Injections followed a counterbalanced sequence and were at least 2 days apart. The injection needle was guided to the site by a stereotactically implanted cannula (outer diameter 0·4 mm)[5] the location of which was then histologically checked. At the time of implantation, an electrolytic lesion (1 mA, 30 s) had been placed in the classical hypothalamic feeding area (lateral part of the lateral hypothalamic area at the level of the dorsomedial nucleus) on the right-hand side of six of the rats. Access

22	−0·49	n.s.	−1·73	0·05	−2·32	0·01

to laboratory chow pellets was given immediately after injection. Food intake during the next 90 min is plotted in Fig. 1 as a percentage of the intake after intrahypothalamic saline injection.

Two pairs of rats showed very similar dose–response relationships: one pair had cannulae in the anterior preoptic area, above the olfactory tubercle (solid squares); the cannulae of the other pair ended at the root of the stria medullaris in the anterior lateral hypothalamic area. The dose–response lines are approximately parallel to that obtained for amphetamine hydrochloride or sulphate by the intraperitoneal route in forty rats from the same batch (crosses, Fig. 1), but are about ten times lower: the difference in depression of intake between the hypothalamic and the peritoneal routes was statistically reliable ($P < 0{\cdot}01$) at the dose of 0·47 μmoles/kg. Each of these four rats ate over 2 g more chow within 30 min after injection of 0·6 μl. of 65 mM noradrenaline than after the control injection. The other two of this group of six rats did not eat after noradrenaline: one cannula was in the posterior hypothalamus, the other was at the base of the brain in the diagonal band of Broca. The dose–response curve was reliably higher for this pair of "non-eaters" than for the two pairs of "eaters" after noradrenaline ($P < 0{\cdot}05$ at 0·47 μmoles/kg) and was not significantly different from the intraperitoneal dose–response.

Two more rats had a lesion placed in the left hand anterior lateral hypothalamic area and a cannula implanted with its tip at the same site. One rat ate more after noradrenaline than after saline and had more of the substantia innominata spared by the lesion than did the other, which did not eat more after noradrenaline. Each of three doses of amphetamine was injected through each cannula on three occasions after 6 h of food deprivation just before access to food. The dose–response curve for the "eater" (solid triangles, Fig. 1) was lower than that of the "non-eater" (open triangles; $P < 0{\cdot}05$).

The consistency of the correlation between the effectiveness of a cannula in guiding noradrenaline to elicit eating and as a route to the site through which amphetamine can elicit anorexia is direct evidence in support of a proposal that amphetamine depresses appetite by chemical interaction with the hypothalamic feeding system[1,6] and in particular the adrenergic portion of that system which is anterior to the classical feeding "centre"[5]. Amphetamine seems to have several different central actions[7], and although it has yet to be shown to have central adrenolytic effects such an action would explain disruption of the adrenergic feeding system. If it can be shown that amphetamine causes anorexia by postsynaptic blockade in the rat, there would then be reason to believe that the feeding system was adrenergic in all species showing amphetamine anorexia. This would be despite the failure of noradrenaline to elicit eating in species other than the rat[8], which may be attributable to interfering effects of intrahypothalamic noradrenaline such as those evident in the rat only after 24 h of starvation (Table 1).

Table 1 summarizes the effects of unilateral injections (1 μl.) of 155 mM sodium chloride with sodium replaced by amine to 65 mM in the case of noradrenaline and amphetamine. These fourteen rats had cannulae with tips in the anterior lateral hypothalamic area and no lesions. Because the effect of noradrenaline on feeding in satiated rats is diminished in rats deprived for 6 h and reversed in rats deprived for 24 h, it is conceivable that amphetamine causes anorexia by the release of endogenous noradrenaline it is known to cause centrally[7], the release being sufficiently great or rapid to disrupt the adrenergic feeding system or another connected system in the same brain region.

Obviously, proof that the anterior diencephalon contains the most sensitive site for amphetamine depression of feeding needs a survey of all the brain. Even then, the strictest criterion of localization of function requires double dissociation between the site of elicitation of anorexia and the site of some other action of amphetamine such as stereotypic motor movement by way of the caudate nucleus[9], temporal discrimination deficits[10] or centrally elicited autonomic or electroencephalogram reactions. So far the adrenergic feeding system in the rat has been localized only by single dissociation[5,11]. If the biochemical pharmacology of amphetamine anorexia differs from the release of dopamine in the caudate which mediates stereotypy, then even "triple dissociation" might be possible.

I thank Miss E. Sherwood for performing the surgery. Work here was supported by the Medical Research Council, and the work done in Yale University Psychology Department was supported by a US Public Health Service grant to Professor N. E. Miller.

BIOLOGY

Halogen Derivatives of 4-Hydroxybenzoic Acid as Root Growth Stimulants and the Importance of Light in this Response

The discovery by one of us[1] of the selective herbicidal activity of 3,5-diiodo-4-hydroxybenzonitrile (ioxynil) and its dibromo- analogue (bromoxynil) has led here to a number of other developments. Thus the high activity of these compounds in uncoupling oxidative phosphorylation[2] resulted in the finding that they are potent molluscicides[1]. Again, the demonstration that iodide ion is liberated when ioxynil is metabolized in soils and plants led to the discovery that inorganic iodides are useful and highly selective herbicides[3]. A further development from the ioxynil work was the examination of certain 2,6-disubstituted phenols as plant growth regulators[4]. Some of these were found to be highly active and equal to 2,4-dichlorophenoxyacetic acid (2,4-D) in certain tests[5]. We now report another development from our research on ioxynil.

In a study of related compounds, the product of hydrolysis of ioxynil, 3,5-diiodo-4-hydroxybenzoic acid (DIHB) was prepared. This acid, although not appreciably phytotoxic when applied to most plant species, was, however, very damaging to certain legumes. In particular, dwarf bean plants sprayed with a 500 p.p.m. solution of the sodium salt of the acid, or watered with this solution, were eventually killed. We have attributed this toxicity to the effect of the iodide ion which was found to be liberated during metabolism. The translocation of DIHB was then examined. In these experiments, in which seedlings were grown with their roots immersed in dilute solution of the compound, there was a marked stimulation

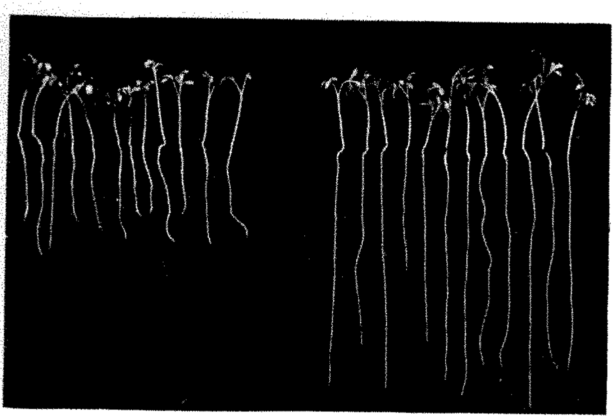

Fig. 1. Stimulation of root growth of cress seedlings (*Lepidium sativum* L.) by treatment with 10^{-5} M 3,5-diiodo-4-hydroxybenzoic acid. Control seedlings are on the left.

of root growth[6,7]. The effect was shown to be particularly striking with seedlings of cress (*Lepidium sativum* L.) where treated roots up to three times as long as control roots were obtained (Fig. 1). Similar stimulation of root growth was demonstrated with the seedlings of other plant species including rice (*Oryza sativa*) (variety 'Jao Leuang II'), although this compound has been reported to be inactive in tests with cucumber seedlings[8]. The nature of the stimulatory response was further investigated by estimating the number of cells in treated and control rice roots and also the mean length of samples of these cells. No evidence was obtained that treatment with DIHB produced an increase in cell number (Table 1); the mean length of treated cells, however, was about twice that of control cells.

Increases in root length resulting from chemical treatment have previously been reported. Thus it has been shown[8] that 3,5-dibromosalicylic acid and 3-nitro-4-fluorobenzoic acid are active in producing increased root elongation in cucumber seedlings. These compounds were therefore re-examined, together with the three 3,5-dihalogeno-4-hydroxybenzoic acids, in a test using cress seedlings carried out as follows.

Cress seeds were sown on 'Terylene' net floating on a solution of inorganic salts containing the test compound, and grown in controlled environmental conditions with 14 h of white light per day. After 64 h the mean length of treated roots was compared with that of roots grown on nutrients alone. The results are expressed as (length of 30 treated roots)/(length of 30 control roots) × 100 and are presented in Table 2.

It will be seen from Table 2 that all three dihalogen substituted 4-hydroxybenzoic acids are active in stimulating cress seedling root growth, the order of activity being iodine > bromine > chlorine. Furthermore, the salicylic and nitro-fluorobenzoic acids are both less active than the diiodo and the dibromo-hydroxybenzoic acid in this test. 3,5-Diiodotyrosine, which has been reported to stimulate root growth in rice seedlings[9], was also included in our experiments; this was found to be less effective than the three 4-hydroxybenzoic acids (Table 2).

Table 1. EFFECT ON RICE ROOTS OF TREATMENT WITH 5×10^{-6} M DIHB FOR VARIOUS TIMES

Table 3. EFFECT OF DIHB TREATMENT (10^{-5} M THROUGH THE ROOTS) ON THE GROWTH OF THE ROOTS OF CRESS SEEDLINGS IN THE LIGHT AND IN THE DARK

	Mean root length (mm)					
	Light			Dark		
Experiment No.	Treated	Control	Per cent of control	Treated	Control	Per cent of control
I	32·8 34·7	13·6 13·8	247*	29·2 32·5	31·3 27·9	104
II	32·8 34·3	9·9 10·1	332*	31·3 31·8	28·9 28·4	110
III	31·1	8·8	353*	30·8 36·1	26·6 30·6	116

* Significantly different from control at 0·1 per cent probability level.

Further work with DIHB established that the promotion of root elongation did not occur when cress seedlings were grown in soil or sand. Because in this case the roots were in darkness it was decided to investigate the responses of cress roots to DIHB treatment in conditions where both roots and shoots were either in light or dark. The seeds were germinated in darkness for 16 h and then maintained either in total darkness or exposed to continuous white light (200–300 l/ft.^{2}) for the remainder of the growth period. The lengths of the roots were then recorded. The results of three experiments showing the growth of seedlings in nutrient solution alone and nutrient containing DIHB (10^{-5} M) are given in Table 3.

From these results it is clear that light inhibits the growth of control roots, and that this inhibition is removed by treatment with DIHB. The results also explain why the response is not shown with seedlings growing in sand or soil where the roots are not exposed to light.

The metabolic fate of DIHB in the roots of cress and rice seedlings has been investigated using the usual chromatographic techniques. It was established with cress that after growth for 64 h in a solution containing DIHB (10^{-5} M) none of the compound could be detected in the roots whether these had been exposed to light or not. A new substance (R_F value of 0·45 on paper chromatograms developed in 2 per cent acetic acid) was, however, shown to be present. This compound, which was also found in the experiments with rice seedlings, yielded DIHB and glucose on both acid and alkaline hydrolyses and showed other properties which indicated that it was a glucose ester.

It is clear from this work that 3,5-dichloro, dibromo and diiodo-4-hydroxybenzoic acids are all capable of modifying the normal responses of roots to environmental conditions. One of these has been shown to be light. We have evidence, however, that other factors operate in this system and these aspects of the work will be described later.

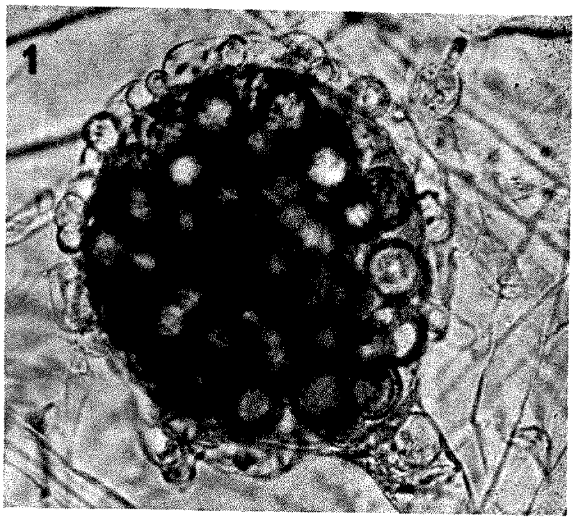
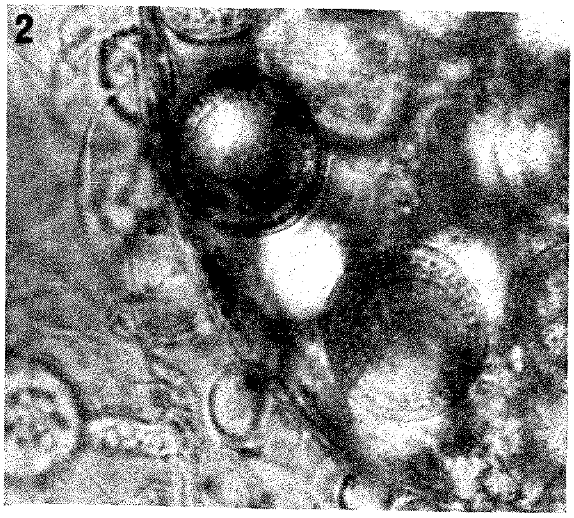
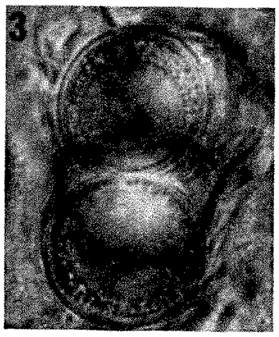
Atlantic Salmon Disease Fungus

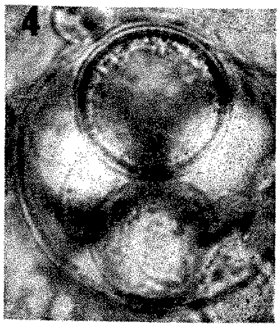
INITIAL reports of the salmon disease from Ireland suggested that the problem was purely bacteriological. This was despite the fact that the presence of a fungus, *Saprolegnia*, constituted the only clear outward symptom by which the disease was recognized. Stuart and Fuller have discussed the possible role of the fungus more realistically and have given details of their mycological researches[1]. With the advent of the disease to the English Lake District, especially in the autumn of 1967, I have also had the opportunity to make observations, and these to some extent parallel those of Stuart and Fuller. Further details of the fungus have, however, become known. *Saprolegnia* isolates were made from diseased salmon, trout and char (*Salvelinus willughbii*) netted in Windermere, and from further specimens of the latter which succumbed in hatchery ponds immediately adjacent to our laboratory. The water supply for the hatchery ponds derives directly from Windermere and is untreated. Using GYS-tellurite agar, a medium previously employed for ecological studies on the Saprolegniaceae[2], the isolates were soon free of bacteria and sterilized hemp seeds were added. These were removed after 8 h and transferred to dishes of sterile lake water where they grew abundant fringes of the fungus. These growth fringes produced sporangia releasing zoospores, but not oogonia. In the absence of these any specific epithet which may be applied to the purely asexual condition (for example, *Saprolegnia parasitica*) can have little or no meaning or usefulness. Accordingly attempts at oogonial induction were set in hand, using oatmeal and cholesterol[3] agars of different strengths with single or paired isolates. Isolates were also paired in simulated natural conditions in contact with sterile mud or soil, following the method of Sherwood[4] for *Dictyuchus*. All these attempts were unsuccessful.

An unexpected by-product of these otherwise abortive researches was the observation that the isolates produced sporangia directly on dry cholesterol agar (Fig. 5); thus this particular medium may prove to be of value for isolating and recognizing fish saprolegnias from mixed populations of fungi in nature. The hemp seed cultures in water were kept for several weeks, with repeated removal and replacement of the dish lids in order to make low power observations. Aerial fungal contaminants (especially of *Penicillium*), sustained by liquid nutrients in the dishes, became established on the surface meniscus in some cases. These contaminated dishes were not discarded because experience has shown that aquatic micro-organisms may give rare fruiting effects in such conditions. Recently, for example, an aquatic actinomycete of the family Actinoplanaceae formed sporangia in a liquid culture contaminated by a *Penicillium*, while uncontaminated cultures were quite devoid of them. This time the fruiting effect has involved the production of sexual structures. Of nine separate isolates under examination four formed oogonia, and these were all in contaminated cultures. For each of the four productive isolates there was at least one parallel uncontaminated culture and this material was all asexual only. The possibility of placing oogonial induction observations such as these on a more strictly scientific basis is encouraged by the work of Park[5]. He has shown that fungus interaction phenomena can be reproducible and even follow logical patterns of prediction. Despite its occurrence oogonial material has been very meagre, averaging only about five mature structures per dish, and a detailed description must be very tentative at this stage. Antheridia are probably diclinous, investing the oogonia so closely that their entire surface is often covered (Fig. 1). Difficulties of interpretation are increased by the frequent germination of zoospores on or near these structures (for example, Fig. 2). Oogonia usually terminate main hyphae and are spherical to clavate, the former 30–120μ in









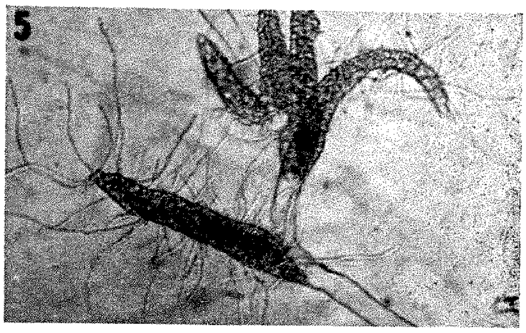


Fig. 1. Large oogonium with typically crowded antheridial attachment (× c. 475).

Fig. 2. Portion of same at higher magnification showing oospore structure. Germinated zoospore low left (× c. 1,135).

Figs. 3 and 4. Small complete oogonia (× c. 1,135).

Fig. 5. Growth on cholesterol agar showing fully formed sporangia. Zoospores encysted in them are sprouting (× c. 95).

diameter The wall is smooth and unpitted Oospores are subcentric 15–25μ in diameter, most being 18μ, and between four and a hundred or more per oogonium (Figs 2–4) Chlamydospores were rarely observed in these particular hemp seed cultures although they had been formed abundantly when paired isolates were grown on sterile mud An outstanding feature is the small size of the oospore These details suggest that the salmon disease *Saprolegnia* cannot be placed immediately in any existing species but may prove to be more closely related to the *S delica–S diclina* complex than to the *S ferax–S monoica* The fungus which Huxley[6] reported and figured from the previous British salmon disease outbreak in 1877 is believed by Coker[7] to have been *Saprolegnia monoica*, although by modern standards the description is quite inadequate The fact that he apparently obtained oogonia so readily, contrary to the experience of other contemporary investigators, casts some doubt on the whole account

Work by many investigators on the Saprolegniaceae has drawn attention to "non-fruiting" (that is, non-oogonial) forms in several genera While in the case of *Saprolegnia* itself these have traditionally been associated with isolations from fish, there is evidence that they constitute a definite proportion of the general saprobic microflora also On Fordwood Beck, a small afferent stream of Blelham Tarn (English Lake District), they were recovered in quantity from a sewage effluent derived from an aerobic percolating filter system[2] Until such forms can be adequately characterized and their distribution patterns examined more closely their full biological significance in the freshwater environment will not be known

I thank Miss J Hardman and Miss D J Usher for allowing me to observe and examine fish in their care and Mrs S M Smith for photography

Stimulation of Transpiration by Cytokinins

CYTOKININS[1] have received considerable attention from plant biologists because they play key parts in systems that regulate growth[2-4] These compounds influence physiological processes such as the induction of cell division, retardation of senescence, promotion of seed germination and promotion of bud developments[5,6] We have already observed that cytokinins initiate another physiological process—transpiration This observation is similar but not identical to a report[7] concerning the stimulation of transpiration of primary barley leaves

Our results indicate that cytokinin stimulates transpiration and induces cell division by a similar, if not the same, initiator system This communication describes similarities between stimulated transpiration and induced cell division and reports the reaction of a number of plant species to the former

The technique used to assess the activity of various compounds has already been described[8], but a brief description of the method is given here Basal ends of leaves from oat plants (*Avena sativa* L) were trimmed to 30 cm and severed ends were placed in an aqueous solution of the compound to be tested Leaves were maintained in the solution for 24 h under continuous fluorescent light (400 ft -candles), and transferred to 15 ml calibrated centrifuge tubes (two leaves in a tube) containing distilled water Treated leaves were placed under continuous fluorescent light for 24 h, and the amount of water lost from the tube was recorded The difference between the water loss from tubes containing treated and untreated leaves was a measure of the quantity of cytokinin in the test solution

Effects of cytokinins on transpiration (Table 1) show that zeatin (supplied by Dr C O Miller of Indiana University) is more active than kinetin and kinetin is more active than N^6-phenylaminopurine Furthermore, the order of sensitivity of the carrot phloem test[9] is similar to the transpiration test—both are more sensitive to zeatin than to kinetin In the cell division[6] and transpiration tests, N^6-hexylaminopurine is active but N^6-dimethylaminopurine is not Furthermore, our dosage response curves for N^6-(2-butoxyethyl) aminopurine in the transpiration test were similar to those obtained by Rothwell and Wright[10] in the tobacco pith test Results indicate a similarity between cytokinin-stimulated transpiration and induced cell division

Several compounds were tested to identify those that stimulate transpiration Certain substituted aminopurines (zeatin, kinetin, N^6-benzylaminopurine, N^6-phenylaminopurine, N^6-hexylaminopurine) increased transpiration, but others (N^6-methylaminopurine, N^6-dimethylaminopurine, 6-mercaptopurine) did not Recently we learned of some new synthetic compounds that possessed cytokinin activity (private communication from Professor R. L Wain, Wye College, who supplied compounds) These cytokinins were of interest because the N^6-substituted groups are straight chains (alkoxyalkyl) Two of these compounds (N^6-2-ethoxyethylaminopurine, N^6-2-butoxyethylaminopurine) were tested, and found to be active in the transpiration test Activity of the butoxyethyl derivative was twenty-fold greater than that of the ethoxyethyl derivative (Table 1)

Table 1 RANGE OF DETECTABLE CONCENTRATIONS OF CYTOKININS USING THE OAT LEAF TRANSPIRATION TEST

Cytokinin	Range (μg/ml)
Zeatin	0 001– 1 00
Kinetin	0 005– 8 00
N^6-Benzylaminopurine	0 005– 8 00
N^6-Phenylaminopurine	>0 01 –10 00
N^6-(2-Butoxyethyl) aminopurine	>0 05 – 4 00
N^6-Hexylaminopurine	0 10 –10 00
N^6-(2-Ethoxyethyl) aminopurine	1 00 – 2 00

Structural requirements for stimulated transpiration were similar to those required for induction of cell division In all cases, a substituted purine skeleton was essential The substituent group may be a saturated or unsaturated ring or a straight chain The length of the carbon chain seemed to influence activity This suggestion was made because N^6-dimethylaminopurine was not active, in the transpiration tests, but N^6-(2-ethoxyethyl) aminopurine was slightly active and N^6-(2-butoxyethyl) aminopurine was very active It appears therefore that straight chain substituents must have at least four carbon atoms.

Indoleacetic acid, 2 4-dichlorophenoxyacetic acid, sym-diphenyl urea and sym-diphenylthio urea as well as adenine, benzylamine and phenylamine did not increase transpiration Furthermore, gibberellic acid did not stimulate transpiration of excised oat leaves This was surprising because a previous report[7] indicated that gibberellic acid stimulated larger increases in transpiration of excised barley leaves than kinetin We observed no qualitative difference in stimulated transpiration within the family Gramineae If gibberellic acid does induce transpiration of primary barley leaves, *Avena* species possess a higher degree of specificity for cytokinins than *Hordeum* species

Although it is difficult to visualize a relation between cell division and transpiration, results suggest that this is the case This relation seems more feasible in view of a recent report by Meidner[11], who observed a rapid increase in the metabolisms of barley leaves treated with kinetins Although an exception (lack of kinetin–indole acetic acid synergism in the transpiration test) to the positive correlation between stimulated transpiration and cell division was observed, numerous similarities warrant attention to this phenomenon It is therefore suggested that increased transpiration, of species of Gramineae, be considered as one of the biological activities for cytokinins

Variation in cytokinin-stimulated transpiration was noted among various species of grasses[8], and so several dicotyledonous species were tested Varieties of *Vigna sinensis* (Torner) Savi (blackeyed peas), *Phaseolus lunatus* L (speckled butter beans), *P vulgaris* L. (pinto and kidney beans), *Glycine max* (L) Merr (soybean), *Helianthus annus* L (sunflower), and *Cucurbita pepo* L (sugar pumpkin) were grown in a growth room and treated as described, except that excised plants were used instead of excised leaves None of these exhibited increased transpiration when treated with various concentrations of kinetin

Excised leaves of *Acer saccharinum* L (silver maple), and *Liquidambar styraciflua* L (sweet gum), collected from field-grown plants, did not respond to kinetin treatment Excised leaves of field-grown *Lolium multiflorum* Lam (ryegrass), however, showed an increase in transpiration when treated with kinetin

Historical Zoogeography of Antelopes

STUDIES of the Bovidae of the later Miocene of Fort Ternan, Kenya[1], and of the lower Pliocene of Samos are producing interesting zoogeographical findings In this communication, names above the species level are from Simpson[2]

Two groups among the Samos antelopes have special relevance, those of the *Palaeoryx* group, and various spirally horned antelopes which have been associated with *Prostrepsiceros* in the tribe Tragelaphini (Strepsicerotini of Simpson[2])

Antelope "species" in *Palaeoryx*, *Protoryx* and *Pachytragus*, and in the smaller *Microtragus*, *Leptotragus* and *Pseudotragus*, have been regarded as Hippotragini Some show clearly, others less clearly, however, resemblances to Caprini the short braincase (all except *Protoryx longiceps* Pilgrim and Hopwood), pronounced bending of the braincase on the facial axis in side view; an anterior surface (*Microtragus*) or an anterior keel on the horn cores (*Pachytragus crassicornis* Schlosser), rather abrupt bending back of the horn core tips (*Protoryx longiceps*); the lower edge of the auditory bulla passing downwards posteriorly to meet the paraoccipital process (*Palaeoryx pallasi* (Wagner) and *Protoryx longiceps*—the only two in which this character is visible), a long narrow ethmoidal fissure alongside the nasals (*Pachytragus crassicornis*, *Protoryx longiceps*), diminished basal pillars on the molar teeth (less in *Palaeoryx pallasi* than others), emphasized styles flanking weak ribs on the upper molars (*Pachytragus crassicornis*, *Protoryx longiceps*), short premolar rows (not *Palaeoryx pallasi*) and small anterior premolars Some characters of later Caprini are missing—for example, widely set anterior tuberosities of the basioccipital, moreover, no Bovid metapodials at Samos are as short as in modern goats, which seems to indicate occupation of different adaptive zones I would not assert that none of the *Palaeoryx* group could possibly be related to Hippotragini, but the evidence strongly favours their assignation to the Caprini, and they have no characters unequivocally resembling Hippotragini

Many names exist for Pliocene and Pleistocene spirally horned antelopes with anticlockwise torsion in the right horn core from the base upwards The three Samos species may be called *Protragelaphus skouzesi* Dames, *Prostrepsiceros woodwardi* Pilgrim and Hopwood, and *Palaeoreas lindermayeri* (Wagner) Pilgrim[3] and Pilgrim and Schaub[4] transferred *Protragelaphus* from Tragelaphini to Antilopini, and I now suggest the same course for *Prostrepsiceros* and *Palaeoreas* *Prostrepsiceros*, in which I include *Hemistrepsiceros*, differs from Tragelaphini by having its parieto-frontals suture not disappearing early in ontogeny, its braincase more bent on the facial axis in side view, the orbital surface of the lachrymal bone not at such a wide angle to the plane of its facial surface, and by having a preorbital fossa *Palaeoreas* shows the last three differences and a deep lateral postcornual groove not found in Tragelaphini It also much resembles *Protragelaphus*, which has such non-Tragelaphine characters as a short basioccipital, an occipital surface with a curved instead of a squared upper edge, and small foramina ovales

Thus the Tragelaphini and Hippotragini are absent from Samos, the Bovids there being wholly Boselaphini, Antilopini, Ovibovini and Caprini Wells[5] concluded 10 years ago that the Cephalophini, Neotragini and Alcelaphini were "essentially African" tribes The Tragelaphini can now be added to this group, but the Hippotragini, although now becoming almost totally African, occur in Arabia as *Oryx leucoryx* (Pallas) and also with Reduncini and an Alcelaphine, in the later Pliocene and early Pleistocene of the Indian and Pakistan Siwaliks[6]

Revision of the Samos Bovidae is thus accentuating the division of the family between Eurasiatic and African forms The family contains Tragelaphini, Cephalophini, Reduncini, Alcelaphini and Neotragini which, except for the Siwaliks record of two of them, are wholly African; and Boselaphini, Saigini, Rupicaprini and Ovibovini which are absent from sub-Saharan Africa The remaining Bovini, Hippotragini, Antilopini and Caprini occur both in Eurasia and sub-Saharan Africa, but in this group Gentry[7] could not trace phylogenetic connexions between African and Eurasiatic Bovini Also the Antilopini can be divided into a Eurasiatic spirally horned group, and into a group of African genera, an exception to this being the widely distributed *Gazella* (including *Procapra*) The Caprini are entirely Eurasiatic and North American except for *Capra walie* Ruppell in Ethiopia

Some fossils relevant to these conclusions remain for future consideration, for example, Bohlin's[8] Chinese "Hippotragini" related to *Protoryx*, Schlosser's[9] small Samos species *Tragoreas oryxoides* and Pilgrim's[10] Chinji "Tragelaphine" *Sivoreas* and his Dhok Pathan supposed Reduncini and Hippotragini, the affinities of Schlosser's and Pilgrim's forms are unclear

It becomes of great interest to see whether Fort Ternan shows us an earlier phase in the history of the African Bovidae At least four antelopes occur there A species of the Boselaphine *Protragocerus* is distinct from *P chantrei* Depéret of the European Tortonian and Sarmatian, and from another species in the Chinji and earliest Nagri of Pakistan to which Pilgrim[11] applied several names including *Strepsiportax gluten* (see also Thenius[12]) Second, there is a new species of Caprini generically inseparable from Pilgrim's[13] *Oioceros*(?) *grangeri* from the Tung Gur Miocene, Mongolia Pavlović and Thenius[14] mention a similar form from Yugoslavia *Oioceros*(?) limb bones at Fort Ternan show more cursorial adaptations than *Protragocerus* These two species constitute about 90 per cent of the recognizable Bovid remains at Fort Ternan Also present is a species agreeing closely with a frontlet from the Nagri gen indet (cf *Tragoreas*) *potwaricus*[15] The fourth species is a *Gazella* with mediolaterally compressed horn cores, rather brachyodont cheek teeth and long premolars The relative smallness of the Fort Ternan antelopes, vestigial alveoli for upper canines in *Protragocerus*, the resemblance of the *Oioceros*(?) to the Tung Gur species, and the brachyodonty of the gazelle give them a more archaic aspect than those of Samos What is most interesting is their relationship at the generic and higher levels to Eurasiatic forms, but not, apparently, to the later antelopes characteristic of Africa

The presence of Boselaphini and Caprini in the late Miocene of equatorial East Africa upsets the strictly geographical part of the concept of Eurasiatic and African divisions of the Bovidae We must evidently allow for past fluctuations of faunal boundaries, and, following Wells[5], can refer to such divisions as "essentially Eurasiatic" and "essentially African" Only in the Tatrot and Pinjor of the Siwaliks is any mixing of the divisions known, apart from that along the wide boundaries of the Palaearctic and Ethiopian realms Unanswered questions include Where did the essentially African Bovidae evolve ? Why are they absent from Fort Ternan but not from the later Pliocene and early Pleistocene of the Siwaliks ? Could more mixing of the divisions be found from further excavations or from further studies of puzzling fossils ?

Saprolegnia parasitica Coker in Estuaries

IN a recent article Stuart and Fuller[1] question whether *Saprolegnia parasitica* Coker should be regarded as a freshwater fungus or a fungus capable of growing and sporing in both freshwater and estuarine environments I find that their review of data concerning the tolerance of Saprolegniaceae to saline environments is misleading because (*a*) they fail to point out the discrepancy in the literature between the influence of temperature on spore production in the freshwater and saline environments, and (*b*) they do not distinguish between vegetative growth with asexual sporulation and the mere presence of viable but unidentified propagules

Some Saprolegniaceae such as *Leptolegnia baltica* Hohnk and Vallin[2] appear to be adapted to life in slightly saline (4–6$^{0}/_{00}$) conditions Te Strake[3] states that the Saprolegniaceae which she isolated from estuarine water of salinity up to 2 8$^{0}/_{00}$ would tolerate greater salinities in vegetative culture at higher temperatures, but that asexual sporulation occurred in the higher salinities only at temperatures above 20° C At 15° C sporulation did not occur above a salinity level of 0 3$^{0}/_{00}$ The temperature data for asexual sporulation quoted by Stuart and Fuller refer to freshwater environments and may not, therefore, be relevant

It is unfortunate that in their pure culture experiments Stuart and Fuller did not use fungi freshly isolated from their fish or the estuaries where they were working, and that they failed to give the temperature at which their experiments were carried out (What is the maximum water temperature of, for example, the Shannon estuary ?)

Te Strake's work shows that viable propagules, which are not identified, are present in estuarine sites The presence of propagules in moving water does not necessarily indicate their site of production This applies to spores of Oomycetes just as much as to spores of Fungi Imperfecti[1,4] Until the site of production is established comments on "habitat nomenclature" have no foundation[5]

To demonstrate that *Saprolegnia parasitica* is not confined to the freshwater environment for vegetative growth and the production of zoospores, it is essential to answer the following questions (1) Does the fungus sporulate equally well in freshwater and estuarine water at temperatures and salinity values comparable with those in the natural environments under investigation ? (2) Do the zoospores remain motile for the same length of time in both environments ? (3) How long do the motile or encysted zoospores remain viable in freshwater and estuarine water ? (4) Will oospores germinate equally well in both environments ? (5) Is the colonization of the substrate (living or dead) comparable in both environments ? (6) What is the computed propagule density required to cause disease in particular hosts in a given environment (river, estuary or the open sea) ?

If this fungus should prove to be a primary parasite rather than a facultative wound parasite, is it not more important to establish the origin and size of the potential spore inoculum and the survival rate of the inoculum in saline conditions, rather than the vegetative growth of the fungus in saline media at unspecified temperatures ?

Chlamydomonas: Adaptation Phenomena in Phototaxis

THE oriented movement of unicellular algae, such as *Chlamydomonas*, is usually regarded as being either positive or negative, when evoked by light of a fixed intensity Until recently it has been difficult to measure phototactic responses of algae quantitatively and rapidly, but methods have now been described for following the phototactic response of a population of algae[1,2] These methods are based on a photoelectric monitoring of the distribution of the algae in a suspension, during exposure to light which evokes oriented response We have adopted the method of Feinleib and Curry[2] essentially unmodified to follow the initial response of cultures of *Chlamydomonas reinhardii* ($WT+2$) The experiments were undertaken to study the variability of the photo-

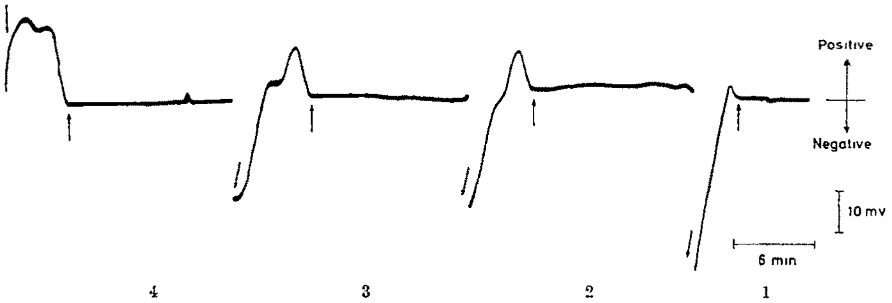

Fig 1 Phototactic response of a 2 day old culture of *Chlamydomonas reinhardii* (1) Initial response negative, (2) response after 3 min strong light followed by 12 min in the dark, (3) response after further 4 5 min in strong light followed by 12 min in dark, (4) response after additional 6 min in strong light and 12 min in dark Recorder speed was 10 in /h Orienting light was 540 ft -candles, white light, falling on blue green filter (Corning 9782) During the dark period the cells were exposed to weak red monitoring light ↑, Light on, ↓, light off, culture mixed

tactic response of cultures of *Chlamydomonas* which we previously observed[3,4] We will show that the same culture of *Chlamydomonas* can be negative or positive in its response to a given fixed intensity of orienting light The organism seems to adapt rapidly to conditions prevailing before measurement Cultures were grown as described before[3,4] in continuous light in an inorganic medium[2], with constant stirring by a magnetic stirrer The phototactic response of the cultures immediately after the orienting light was switched on was observed Cultures frequently did not respond in a clear cut manner, a slight positive response was often followed by a negative one. If cultures were exposed to light in the apparatus for increasing periods of the time and their phototactic responses were measured periodically, the initial positive response increased and the subsequent negative one decreased (Fig. 1) These results indicated that the cells were adapting to the light so that their phototactic response changed. The following experiment was therefore undertaken. A culture was selected the initial response of which was negative This culture was now illuminated for 2 h with 200 ft -candles light from an incandescent lamp and its response again measured. The culture which had shown a strong and immediate negative response now responded positively to the same light intensity The culture was now returned to darkness for 75 min and its response was measured again As Fig 2 shows, it now responded negatively

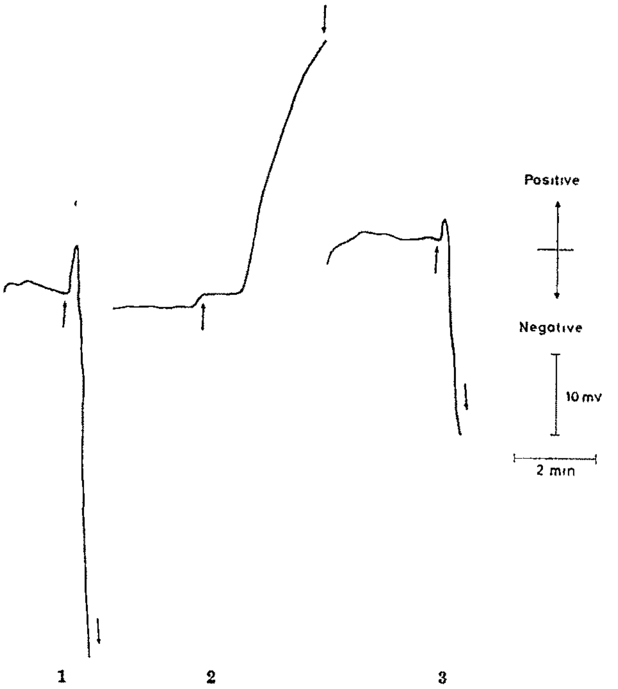

Fig 2 Phototactic response of 4 day old culture of *Chlamydomonas reinhardii* (1) Initial response, (2) response after exposure for 2 h to incandescent light (200 ft -candles), (3) response after additional period 75 min in dark The orienting light in all cases was monochromatic blue-green light (Corning filter No 9782) Intensity was 250 ft -candles, white light before filter Recorder speed was 30 in /h ↑, Light on, ↓, recorder off

These results clearly show that a culture of algae can rapidly change its phototactic response to a given fixed light intensity from negative to positive and vice versa It can be assumed that the algae adapt their phototactic behaviour in response to the light intensity to which they are exposed before measurement This adaptation is probably caused by metabolic changes which take place during the period of adaptation, and they are possibly connected with photosynthesis The cultures have a generation time of more than 12 h and were not synchronized, so division of the cells is not likely to be involved Microscopic observation gave no indication that the algae were dividing during the period of adaptation No changes in the *p*H of the medium could be observed during adaptation

These results indicate the extreme caution which must be exercised when referring to algal cultures as positive or negative in their response to light The nature of the response to a fixed intensity of orienting light can change rapidly, depending only on treatment immediately before measurement No absolute positive or negative responses seem to exist It seems to us that the diurnal upward and downward movement of algae in their natural environment, which has been ascribed to positive and negative phototaxis (ref 5), must also be re-examined

Light Induced Uptake of Potassium and Chloride by *Chlorella pyrenoidosa*

RECENT studies of mechanisms of ion transport across the membranes of isolated mitochondria and chloroplasts have been designed to show whether the energy is derived directly from electron transport or from high energy chemical intermediates[1,2] A similar argument concerning the active transport of ions across the protoplasmic membranes of intact animal and plant cells[3] has also been considered for many years Perhaps the most convincing evidence that the active transport of an ionic

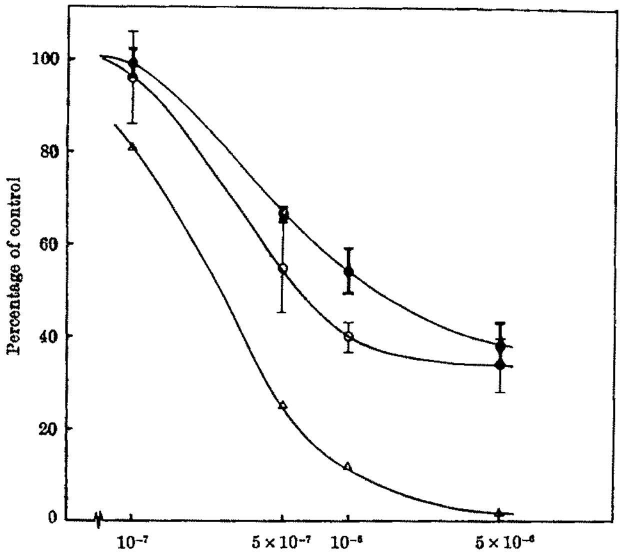

Fig 1 The effect of low concentrations of DCMU on the influx of potassium (●), chloride (○) and oxygen evolution (△) The results are presented as the percentage of the controls and the standard errors of the regression lines are given for the tracer experiments

species is intimately linked with electron transport has come from studies on the giant cells of *Nitella translucens*[4] and *Hydrodictyon africanum*[5] In these algae, it has been shown that the light stimulated influx of chloride, unlike the uptake of potassium, is independent of photophosphorylation and seems to be associated with the oxygen evolving system 2 of photosynthesis

This communication reports some work on *Chlorella pyrenoidosa* to test whether the light promoted uptake of potassium and chloride into these cells is driven by two different energy sources as suggested for the vacuolated coenocytes The unidirectional fluxes of these ions were measured using potassium-42 and chloride-36 and all the experiments were conducted in culture medium The internal radioactivity was assayed, after sedimenting the cells on 'Millipore' filters and washing, by means of an end-window Geiger tube

Table 1 LIGHT AND DARK INFLUXES* OF POTASSIUM AND CHLORIDE INTO *Chlorella pyrenoidosa*

Ion	Influxes from culture medium†			
	$\mu\mu$ moles/s 5 mm^3 packed cells		$\mu\mu$ moles/s cm^2	
	Dark	Light	Dark	Light
K	3 4 ± 0 1 (19)	19 1 ± 1 0 (31)	0 18 ± 0 01	1 03 ± 0 10
Cl	0 35 ± 0 01 (6)	2 32 ± 0 26 (9)	0 019 ± 0 006	0 12 ± 0 02

Results are quoted as ± standard error of the mean, number of experiments on which mean is based is given in parentheses The cells were illuminated by white light from an incandescent source at an intensity of about 500 ft -candles

* Unidirectional influxes in the absence of net ion movement

† The culture medium (*p*H 6 8) contained (mM) KNO_3 5 00, Na_2HPO_4 $2H_2O$ 0 50, KH_2PO_4 0 50, $MgSO_4$ $7H_2O$ 2 00, $Ca(NO_3)_2$ $4H_2O$ 0 25, KCl 1 00 and trace elements, 2 ml /l as given by Hutner *et al*[6]

Table 1 shows the mean values of the light and dark influxes and gives an estimate of each flux in terms of unit area of cell surface It can be seen that the action of light is to stimulate the influx of these ions by a factor of about six. Such a sensitivity to light does not necessarily suggest that an active pump is involved. It has been possible, however, to obtain a direct measurement of the potential difference between the interior and exterior of these cells when bathed in culture medium This procedure will be reported elsewhere, but the results strongly indicate that potassium and chloride are transported into *Chlorella* against the electrochemical potential gradient A mean potential difference (±*S E M*) of −40±2 mV was obtained from sixty-five cells while the Nernst equilibrium potentials, calculated from the distribution of these ions, were −71 mV for potassium and +8 mV for chloride Thus it would seem that, with respect to the direction of active transport of these two ions, *Chlorella* shows the same characteristics as *Nitella* and *Hydrodictyon*.

The sensitivity of these apparent active light stimulated influxes to 3 - (3,4 - dichlorophenyl) - 1,1 - dimethylurea (DCMU) can be seen in Fig. 1. Oxygen evolution, as measured with a platinum polarograph, was partially inhibited by concentrations of 10^{-7} to 10^{-6} M while complete inhibition occurred at 5×10^{-6} M. Over the same concentration range, the influxes of potassium and chloride, measured by double labelling, were reduced by equal amounts with about 40 per cent of the uptake of both ions persisting at concentrations of DCMU which totally inhibited oxygen evolution Such findings are quite different from those obtained with the two coenocytic algae, in which the influx of chloride was much more sensitive to this herbicide than was the potassium influx

The results suggest that both these photostimulated fluxes into *Chlorella* contain components which are independent of net electron flow and pseudocyclic flow. Such components could derive their energy from cyclic photophosphorylation in a manner similar to that suggested for glucose assimilation by this same alga[7]. Indeed, it was also found that when the cell suspensions were gassed with nitrogen free of carbon dioxide the influxes of the two ions were reduced to approximately 50 per cent of the aerobic controls To test whether these DCMU resistant and anaerobic components were partially or wholly dependent on cyclic electron flow, some experiments using the cytochrome *b* inhibitor, antimycin A, were carried out and the results shown in Fig 2 It can be seen that both these components were inhibited by this antibiotic, with the chloride influx showing the greater sensitivity This difference in the response of the two ions to increasing concentrations of the poison may simply reflect a larger passive component of the potassium influx as compared with the chloride uptake Nevertheless, it is clear that both ionic influxes show some requirement for the participation of cyclic electron flow

Further experiments using the uncoupler carbonyl cyanide *m*-chlorophenyl hydrazone (CCCP) also showed the light stimulated aerobic uptake of potassium and chloride to be equally inhibited, with a maximum effect at concentrations of about 10^{-5} M. Moreover, when the relative quantal efficiencies of the influxes were measured for cells illuminated by 680 and 705 mμ light, the same

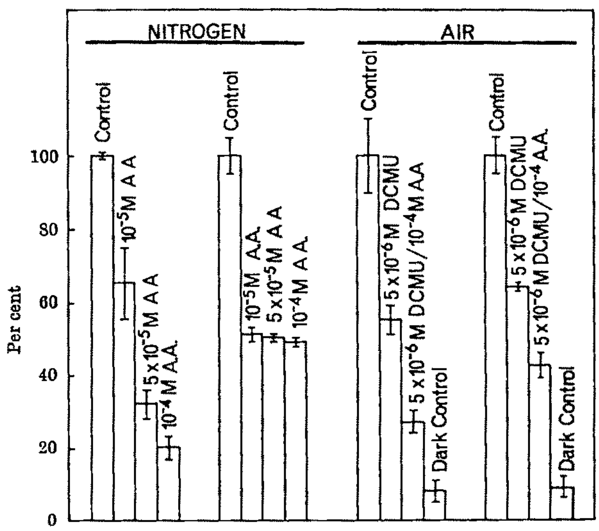

Fig 2 The effect of various concentrations of antimycin A (AA) on the anaerobic light stimulated uptake of potassium and chloride and also the effect of this antibiotic on the DCMU resistant influx components of these two ions The standard errors of the regression lines are given

values were obtained for both ions The measurement of oxygen evolution in the same lighting conditions, however, suggested that the two photosystems had not been separated This is in agreement with Hommersand[8], who encountered the same difficulty with this strain of *Chlorella* (stock number 252, Culture Collection of Algae, Indiana University) and who concluded that the overlap of the two pigment systems was better than usual

The only obvious difference between the influx of chloride and potassium into *Chlorella* found during this work was the light intensity at which the maximum rates were obtained The chloride uptake saturated at an intensity which was 25 per cent of that needed to saturate the rate of potassium uptake With an incandescent light source, the chloride uptake saturated at $1 5\times10^4$ ergs/cm^2 s, while both photosynthesis and the potassium influx saturated at $5 5\times10^4$ ergs/cm^2 s

In summary, it is most probable that the light stimulated uptake of potassium and uptake of chloride by *Chlorella* are active processes There is no clear evidence, however, that these two fluxes are dependent on different sources of energy It also seems unlikely that they obtain the necessary energy directly from electron transport but possibly utilize ATP derived from cyclic and non-cyclic photophosphorylation. The close association of active chloride influxes with oxygen evolution may be a feature only found with vacuolated cells, although some recent work on *Elodea densa*[9] does not support this

Action of Potato Peel Extracts in modifying Tuber Dormancy

Differences in length of tuber dormancy which are related to mineral content have been found during work on the effect of the mineral nutrition of the potato plant on the performance of its progeny To relate these differences to tuber biochemistry, it was necessary to know the effect of tuber extracts on the dormancy of whole tubers Previous attempts to control dormancy by treating potato pieces with either tuber peel extracts containing the inhibitor-β complex[1] or with one of its components, abscisic acid, have failed[2], although the disappearance of this complex from the tuber has been correlated with the breaking of dormancy[3] It is also known that cutting a tuber causes a wound reaction which leads to the breaking of dormancy[4]. Furthermore, the practice of soaking tubers in concentrated solutions for up to 24 h produces anaerobic conditions which could have effects on dormancy as great as those of the extract being supplied

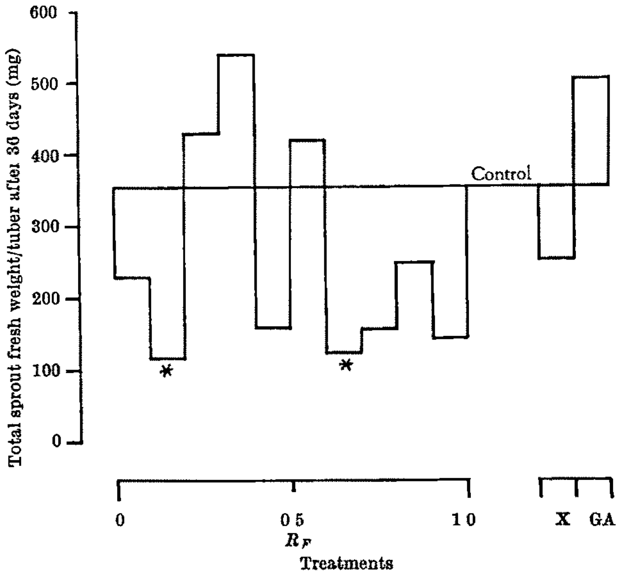

Fig 1 Sprout growth after 36 days, related to water control Treatments are R_F 0 1–1 0 of chromatograms of tuber peel extracts X, R_F 0 2, 0 4 and 0 7 combined, GA, 1 p p m gibberellic acid * Depression, significant at 5 per cent level, when compared with control

I felt that a more realistic technique would be to use whole tubers which were in contact with a very dilute solution for a long period but only partly immersed, so preventing anaeroby Accordingly, whole mature non-sprouting tubers each weighing 50–90 g were used as assay material in this experiment.

The peel from 25 kg of freshly collected mature tubers was extracted with 80 per cent methanol, filtered, and the filtrate was reduced under vacuum The resulting aqueous solution was acidified to *p*H 3 and partitioned with ethyl acetate The reduced ethyl acetate fraction was separated by descending paper chromatography using an isopropanol: ammonia water (10 1 1) solvent system Thirteen unreplicated treatments were used, comprising the 10 R_F strips from the chromatograms, a combination of strips of R_F 0 2, 0 4 and 0 7, gibberellic acid and a blank strip control The strips were placed in polythene bags and to each was added 100 ml of distilled water and nine potato tubers except for the treatment with gibberellic acid in which a 1 p p m solution of gibberellic acid was used instead This method of application is a modification of Goodwin's technique for breaking dormancy[5]

After 8 days in the dark at 13° C, many of the tubers had developed "soft-rot" (also noted by Goodwin), but the extent of this varied with the treatments (Table 1). There was no rotting of tubers treated with strip R_F 0 7 which is the R_F at which the inhibitor-β complex usually

* X, Mixture of R_F 0 2, 0 4 and 0 7 † Decrease significant at 5 per cent level, when compared with control

occurs in this system The rotten tubers were discarded and the healthy ones removed from the bags and placed in trays.

After 21 days sprouts had become visible and were recorded. Very few eyes were sprouting under treatments R_F 0·2 and 0 7, but almost half were sprouting under treatment R_F 0·6 and nearly three-quarters in the control R_F 0 2 and 0 6 represent the areas where a neutral inhibitor and gibberellic acid are usually found in this system

Records were made of total sprout length for each tuber after 29, 33 and 36 days, and total sprout weight for each tuber at 36 days All indicated a substantial reduction in sprout growth produced by treatments R_F 0 2, 0 5 and 0 7 when compared with the control Salicylic acid, a mild inhibitor, usually occurs at R_F 0 5 in this system There were increases in sprout lengths produced by R_F 0 3, 0 4 and 0 6 The mixture of R_F 0 2, 0 4 and 0 7 produced growth intermediate between the extremes given by treatments R_F 0 4 and 0 7, which suggests that the auxin usually found in R_F 0 4 (ref 6) will relieve the inhibition produced by the compounds at R_F 0 2 and 0 7.

These preliminary results suggest that the inhibitor-β complex does prolong dormancy, the evidence for which until now has been circumstantial A considerable effect was also produced by treatment R_F 0 2 This is the area of the chromatogram where neutral inhibitors noted by Varga and Ferenczy occur[6] Although these inhibitors do not disappear at dormancy break[7], this demonstration of what must be presumed to be a dormancy prolonging activity suggests an indirect role in the maintenance of dormancy which has still to be elucidated

Vulval Bodies in Certain Species of *Heterodera*

DIFFERENCES in the vulval region of the Tylenchid nematodes of the genus *Heterodera* are of considerable systematic value[1-3] The "bullae", knob-like structures[4] not present in all species, are of particular importance They seem to be endocuticular, but their function is unknown This communication reports the presence in the four species so far examined of other endocuticular bodies closely associated with the vulva itself My attention was directed to them by Dr C. Ellenby, who first observed them in sectioned material of *H rostochiensis* and *H tabacum* (unpublished work)

The "vulval bodies", as it is proposed to call them, are clearly shown in Fig 1, a longitudinal section of a white cyst of *H rostochiensis* They have also been found in *H schachtii*, a bullate cyst with vulval cone, and in *H cacti*, an abullate cyst with vulval cone In both these species the vulval bodies are apparently less well developed than in *H rostochiensis* and *H tabacum* It is too early to say, however, whether the apparent differences in size between the vulval bodies of different species are of systematic value

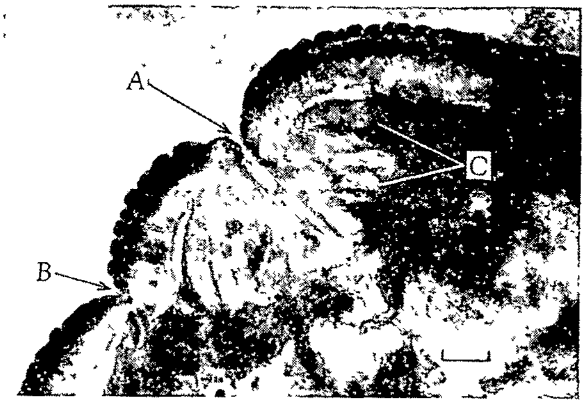

Fig 1 Longitudinal section of white cyst of *H rostochiensis* showing vulval bodies *A*, Vulva, *B*, anus, *C*, vulval bodies (Scale=10μ)

The vulval bodies are embedded in hypodermis, and in all the species examined they are closely associated with the fenestra, the thin peri-vulval region, it would be more correct to say that they are attached to the fenestra, because if this is detached from the cyst wall by manipulation, the vulval bodies are detached with it Their function is unknown If detachment of the fenestra of the fully formed cyst is vital for the emergence of larvae[1], then perhaps the vulval bodies may be involved in some way in this process. They do not seem to be involved in mating, for comparison of fertilized and non-fertilized cysts showed that the vulval bodies increased in size after fertilization in the former, but showed no such change in the latter

Dry Season Biology of *Anopheles gambiae* Giles in the Sudan

COLLECTIONS of mosquitoes have been made regularly throughout the dry season in the desert west of Omdurman, Sudan, by means of pyrethrum-spraying, well-traps and hand catching The results indicate that adult female *Anopheles gambiae* (sp B ?) Giles survive throughout the dry season, but with a change in their physiology and behaviour The insects were found to hide in dwelling huts (87 7 per cent), in cracks down dry wells (8 5 per cent), in disused or ruined houses (3 2 per cent) and in rabbit and rodent burrows (0 5 per cent) Dissection showed that 77 1 per cent of the nulliparous females captured were engorged with blood Of these, 90 6 per cent contained human blood The ovaries evidently undergo only one gonotrophic cycle during the dry season, developing extremely slowly so that, when the rains come, the gravid females are ready to oviposit These mosquitoes are apparently unable to lay eggs during the dry season

Laboratory studies have also been carried out on mosquitoes bred in an insectary About 10 per cent of nulliparous females, kept from the beginning of the cool dry season in conditions of temperature and humidity approximating to natural conditions, lived for periods up to 206 days Those maintained in similar conditions from the beginning of the hot dry season lived for a maximum of 51 days Individuals reared towards the end of the hot dry season did not live long. The ovaries of these experimental individuals did not mature, although the insects took frequent blood meals. Some of them survived for as long as 59 days' fasting. By weighing starved females before and after feeding, it was found that they took incomplete blood meals. Gonoactive females, reared in the insectary, however, took complete blood meals. Incomplete blood meals in gonoactive females evidently result in the failure of ovarian development.

Laboratory experiments also showed that low temperatures (20° ± 0.5° C) and a low threshold of relative humidity (10–20 per cent) induce a state of arrested development. Low humidities at normal temperature produce an inhibition of oviposition in gravid females for 4–14 days.

ANIMAL BEHAVIOUR

Specific Habituation by Chicks

CERTAIN changes in the sensory input of an animal are immediately followed by a reaction from that animal which is the same for a variety of different changes. This orientation reaction was first described by Pavlov[1], who referred to observable changes in posture such as turning the head to look or listen in a particular direction. Many other changes within the animal have been found to coincide with such movements and are therefore considered to be part of the orientation reaction[2]. Lynn[3] has summarized the various components of the reaction which have been measured.

Repetition of a change in environment leads to reduction in the duration and extensiveness of the orientation reaction and, as far as present recording techniques can determine, to its final disappearance. After an environmental change has occurred at intervals until the disappearance of the orientation reaction, slight modification of that change may be followed by the reappearance of the reaction[2]. The degree of modification necessary for such a reappearance depends on various factors and is limited by the acuity of the sensory system concerned. Sokolov[2] has described experiments in which animals habituated to a tone of a particular pitch or duration showed a reaction, measured physiologically in various ways, when the pitch or duration was altered. To explain such results, Sokolov has proposed that with repeated presentation of a stimulus a "neuronal model", related to it, is gradually formed. Responses to subsequent stimuli depend on a comparison between the stimuli and the model. If that further input corresponds exactly with the model, no reaction occurs, but a mismatch of any sort is followed by an orientation reaction and, presumably, by a modification of the model.

This and other theories of the mechanisms of habituation are reviewed by Lynn[3]. The physiological mechanisms suggested by Sokolov[2] to account for his observations have recently been questioned by Horn[4], who points out that some aspects of habituation can be explained without postulating an active gating process after the matching of model and stimulus. Horn also quotes evidence, for some situations, against Sokolov's statement[2] that the model and matching system are located in the cortex, and that the afferent signal to the reticular formation, where the behavioural change is presumed to be initiated, is controlled by fibres originating in the cortex. Horn's proposals do, however, include a model forming system, which in the case of time dependent experiments may be two-stage, and thus do not conflict with Sokolov's behavioural hypothesis, only with some of the mechanisms he suggests.

The aim of this study was to test Sokolov's general hypothesis using behavioural measures and to see whether the theory applied also to birds. The reactions shown by young domestic chicks to a regularly repeated light flash and the effects of varying the duration of that flash are described.

Chicks were reared from hatching singly in grey-walled pens[5] with a 6.3 V torch-bulb present on the wall. This bulb could be silently illuminated by an automatic timing mechanism. The observer was never seen or heard by the chicks. The birds were watched individually and their behaviour was recorded continuously using a moving paper event recorder. Every initiation, termination or change of direction of a movement, and the bout length of the fifteen most frequent measures of behaviour, were recorded.

When the seventeen chicks used in the experiment were 2–3 days old, the torch-bulbs were illuminated on a regime of 10 s on, 20 s off. This was the first illumination change seen by the chicks since being placed in the pens. Each bird was watched for 2.5 min before and for 2.5 min after the initial illumination. The regime was maintained for 18–24 h, after which the chicks were watched for a further 2.5 min and then for 15 min while the duration of the bulb-on period was altered at intervals.

The changes in the behaviour of chicks which result from the illumination of a torch-bulb in their home pen have been reported elsewhere[5]. A major change in behaviour during the 3 s after the first bulb illumination was shown by 94 per cent of the chicks watched in this experiment. The exact nature of the change varied from one individual to another, but any call, jump, head-shake, head turn so as to fixate the bulb, or abrupt termination or change in direction of an activity, is referred to here as a major change. The beginning or end of bouts of frequently occurring activities are called minor changes in behaviour. A comparison of the 2.5 min before the initial bulb-on with the 2.5 min after, using two-tailed Wilcoxon matched pairs tests, showed increases in calling loudly and jumping ($P < 0.01$), fixating the torch-bulb ($P < 0.01$), and moving close to the torch-bulb ($P < 0.05$).

When each chick was watched for 2.5 min after the regime had been operating for 18–24 h, no bird showed an important change in behaviour during the first 3 s after any bulb-on, and minor changes occurred in only 2 per cent of these 3 s periods. Thus the reaction to the light flash, as assessed by measurement of overt behaviour, had disappeared.

The illumination regime was then altered in one of two ways (Fig. 1). The 30 s period which included 10 s bulb-on and 20 s bulb-off became (*a*) 5 s on, 25 s off ($n = 8$); or (*b*) 15 s on, 15 s off ($n = 9$). After one such alteration, the previous regime was reinstated for five 30 s periods before another change of the same type. This procedure was repeated so that each bird was subjected to the

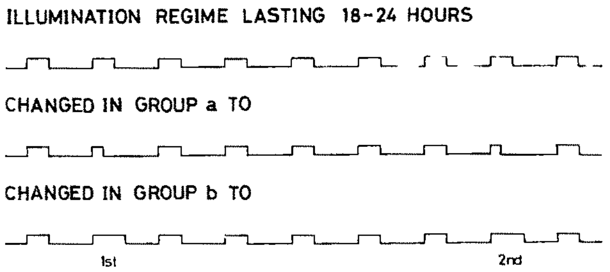

Fig. 1

changed regime five times at 3 min intervals The only change detectable by the chicks was in flash duration, for the timer controlling the regime was inaudible to them, being in a different room, and the use of a constant voltage supply prevented any change in bulb brightness

If a model of the regular input were formed and an overt reaction occurred when the subsequent input did not match that model, it would be expected that the behaviour of the chicks would show a change in group (*a*) at 5 s after bulb-on, that is to say, when the bulb went off too early, and in group (*b*) at 10 s after bulb-on, that is to say, when the bulb would normally have been extinguished but was not Such changes should be apparent within 3 s, so that data from the record of continuous observation which are quoted here are for 5–8 s after bulb-on in group (*a*) and for 10–13 s in group (*b*)

During the five 30 s periods before the alteration in flash duration, none of the chicks in group (*a*) showed a major change in behaviour between 5 and 8 s after bulb-on, and none of those in group (*b*) showed a major change between 10 and 13 s after bulb-on In the five periods during which the flash duration was altered, however, major behaviour changes were shown by 83 per cent of group (*a*) birds between 5 and 8 s after bulb-on and by 100 per cent of group (*b*) birds between 10 and 13 s after bulb-on

The most obvious changes in behaviour were the fixation of the bulb for at least 2 s and a sudden shake of the head or whole body accompanied by a brief cessation of whatever activity was being performed Other frequent changes included the initiation of a series of rapid pecks directed at the ground or the wall or sudden isolated pecks, scratches, calls or preening Some birds walked towards or away from the bulb A comparison of the frequency of major changes in behaviour before altering flash duration and in the five successive periods in which the duration was altered is shown in Table 1

Table 1 INCREASE IN BEHAVIOUR CHANGES AFTER ALTERING FLASH DURATION*

Group	*n*	Before altering flash duration			Total	After altering flash duration				
		0–3 s	5–8 s	10–13 s	%	1st	2nd	3rd	4th	5th
(*a*)	8	0	0	2	50	75	63	50	33	0
(*b*)	9	0	2	0	49	44	33	56	44	67

* Each figure is the percentage of major behaviour changes during 3 s observation

"Before altering flash duration" figures are for the 3 s starting at bulb on, and 5 and 10 s after "After altering flash duration" figures are for 5–8 s after in group (*a*) and 10–13 s in group (*b*) The total percentages for all five periods and the figures for successive periods are shown.

For group (*a*), a comparison of the behaviour of each bird in the 5–8 s after bulb-on during the five periods before altering flash duration, with the corresponding time during the five periods in which the duration was altered, gave a two-tailed value for P of 0 02 (Wilcoxon matched pairs test) For group (*b*), in a similar comparison but for the 10–13 s after bulb-on, $P < 0\ 01$ two-tailed

In group (*a*), 75 per cent of the chicks reacted to the early extinction of the bulb when this first occurred, but none reacted to the fifth duration change This change from a 10 to a 5 s flash is presumably large enough to be readily detected as a discrepancy between previous and present input but, as far as is apparent from behavioural observation, the "model" is modified rapidly Fewer birds reacted initially to a change from a 10 to a 15 s flash, but the total percentage of reactions over the five changes was almost the same This change may be less easily detected than that from 10 to 5 s and the "model" is not modified as rapidly

The recording was continuous, so it was possible to look for behaviour changes during periods other than those in which the flash duration was altered The chicks often showed changes in behaviour when the bulb was illuminated as usual in the 30 s period following that of altered duration For both group (*a*) and group (*b*), in 28 per cent of the bulb-illuminations following periods in which flash duration had been altered, major changes in behaviour occurred in the first 3 s Results of Wilcoxon tests comparing these 3 s periods with the corresponding periods before altering the duration for both major changes, and major and minor changes combined are as follows group (*a*), major change $P > 0\ 05$, major or minor change $P = 0\ 05$, group (*b*), major change $P = 0\ 05$, major or minor change $P = 0\ 01$ (all two-tailed) This effect of an environmental change on subsequent reactivity to a regular change is similar to some of those described for various mammals[2]

Using entirely behavioural measures, these results support the hypothesis that the mechanisms underlying such reactions include the formation of a model of the repeated sensory input and some system for comparing subsequent input with that model This comparison could be active, as required by Sokolov, or passive as suggested by Horn A mismatch may be followed by an overt reaction, a change in the likelihood that the animal will respond to further input, and modification of the model

I thank Professor W H Thorpe for facilities at the Sub-Department of Animal Behaviour, University of Cambridge, Professor R A Hinde for much advice and Dr G Horn for discussion of the manuscript The work was supported by a grant from the Science Research Council

APPLIED SCIENCE

Argon Sorption at 77·4° K on a Microporous Glass

PHYSICAL adsorption should be a fast process, but several glasses have been observed to interact with gases—both inert[1] and otherwise[2,3]—slowly, the process taking a very long time During recent investigations into the structure of glass fibres using a selective leaching technique, we have prepared a porous glass, predominantly silica in composition, which exhibits slow sorption of gases over long periods of time These sorption properties can be very greatly modified by thermal pretreatment

A typical characterization of a porous product of a leaching process would involve the measurement of a pore size distribution and a surface area, and their variation as a function of thermal treatment This was found to be ineffective for the system studied because the adsorption isotherms of the usual probe gases showed a marked dependence on time A certain degree of characterization of the silica fibre properties was possible by observing the rates of inert gas sorption as a function of uptake and thermal treatment

The sorption kinetics of argon by the microporous glass were followed gravimetrically using a vacuum microbalance Before the sorption experiments, the samples were heated *in situ* at the required temperature for at least 16 h at pressures of less than 10^{-5} mm of mercury Further treatment at the same temperature did not normally result in any further loss of weight or change in the sorption kinetics

The rate of sorption of argon was found to be virtually independent of pressure in the relative pressure range 0 05 to 0 5 at 77 4° K but to be strongly dependent on

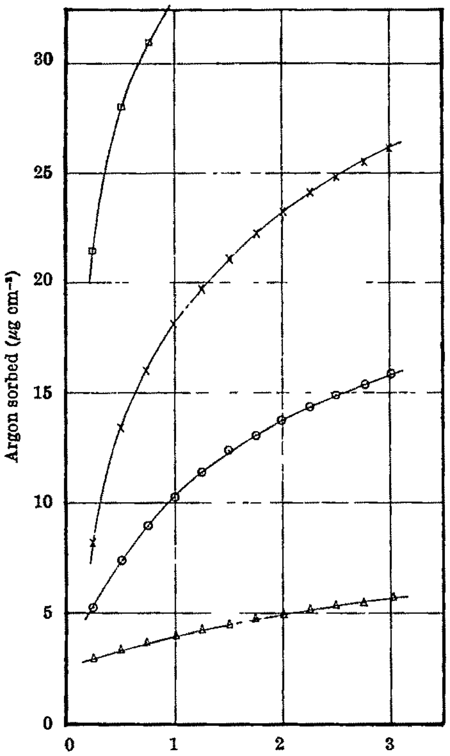

Fig 1 Argon sorption by a microporous glass produced by acid leaching Argon pressure ~0 8 cm of mercury Temperature 77 6° K □, 335° C (16 h), ×, 200° C (18 h), ○, 200° C (2 h), △, 120° C (16 h)

thermal treatment and history Adsorption experiments carried out with benzene at 26° C also showed some time dependence, but the rates were of the order of 10^4 times smaller and outside the limit of sensitivity of the apparatus

The krypton surface area was determined by using a volumetric technique and was found to agree to within 5 per cent with the value found for the original glass. The method was not of sufficient sensitivity to investigate slow processes The interaction of water with the thermally treated sample was quite complex and invalidated its use as a molecular probe, because the structure of the microporous glass was irreversibly altered during an absorption experiment

Figs 1 and 2 show the results of a series of sorption experiments on the microporous glass after a variety of pretreatments It is evident that water has had a sintering effect on the structure Fig 3 illustrates the sintering effect of temperature on the structure, in that the rate of argon sorption at constant uptake increases progressively as the temperature increases up to 450° C, and then sharply decreases, virtually ceasing below 600° C This behaviour is mirrored in the dimensional changes observed in the samples as a function of temperature, and is in contrast to the behaviour observed in porous 'Vycor' glass[4], where no appreciable consolidation occurred below 900° C

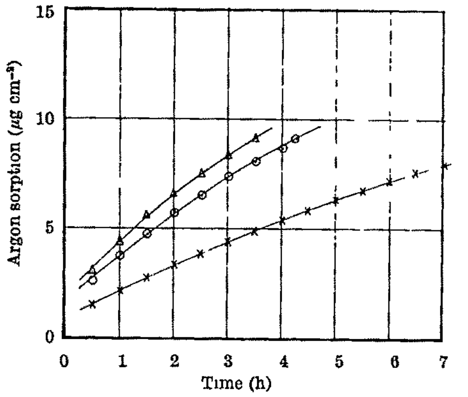

Fig 2 Argon sorption by a microporous glass after heat treatment to 450° C and rehydration at 20° C Argon pressure ~0 8 cm of mercury Temperature −195 6° C ×, 290° C (16 h), ○, 400° C (16 h), △, 490° C (16 h)

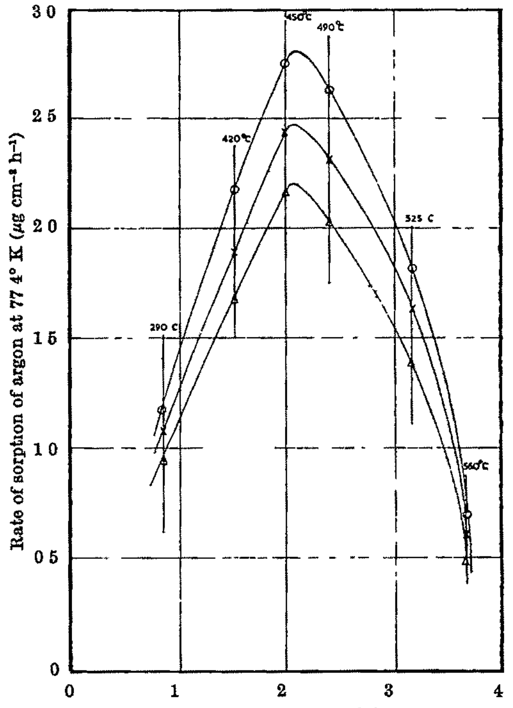

Fig 3 The influence of thermal treatment and associated weight loss on the rate of argon sorption at 77 4° K at constant uptake ○, 0 375 μg cm^{-2}, ×, 0 5 μg cm^{-2}, △, 0 625 μg cm^{-2}

The evidence points to the existence of an interior volume within the silica fibres, the entrance to which is controlled by fine pores of dimensions similar to the size of the argon molecule, for krypton and benzene are apparently excluded or have a very much slower sorption rate If its behaviour is compared with that of the molecular sieve chabazite, which shows a similar type of slow sorption process with hydrocarbon molecules[5], it would be necessary to assume a smaller controlling pore diameter than that present in chabazite because the latter shows no slow sorption with argon It would require a pore diameter in the region of 3 84 Å or less to produce the required time dependent sorption and, according to Kington and Laing[6], it is more likely that a diameter of 3 1 Å or less would in fact be necessary to cause the movement of argon to become an activated process in a porous system

The mechanism of sintering of the porous product of selective leaching of various glasses is to be studied in more detail with particular emphasis on the effects of water vapour and thermal pretreatment

BOOK REVIEWS

PROBLEMS OF THE QUASARS

Quasi-stellar Objects

(A Series of Books in Astronomy and Astrophysics.) By Geoffrey Burbidge and Margaret Burbidge. Pp. viii + 235. (San Francisco and London: W. H. Freeman and Company, 1967.) 70s.

Some five years ago several papers were published in one issue of *Nature*, and they were the first to introduce quasars to astronomers and to the scientific public. In his contribution Cyril Hazard showed how the position of the two parts of the radio source *3C* 273 fitted exactly on to the position of the corresponding optical object. In another paper Maarten Schmidt explained the emission spectrum of part B of the object by assuming that it had been red-shifted by an amount $z = 0.16$. Since then astronomers have been wrestling with the problem of the quasars.

The observers have made astonishing progress in their work. Identifications have been made for well over a hundred quasars, with red-shifts that range up to $z = 2.22$. The radio astronomers have measured angular diameters and found that many quasars have unresolved components smaller than 0.01 seconds of arc. Infrared observations have shown that *3C* 273, at any rate, emits most of its energy at sub-millimetre wavelengths. Most puzzling of all is the discovery that many quasars are variable, with relatively abrupt brightenings and darkenings that sometimes occur within one or a few days. Finally, some of the more highly red-shifted objects were found to have absorption as well as emission lines, and although z emission is usually close to z absorption the two values of z seem never quite to coincide.

Clearly the observers have done a vast amount of work, and Margaret and Geoffrey Burbidge, in particular, have contributed very largely to our knowledge of the observed properties of quasars. In this book they have collected together and assessed all the accessible observational results found by themselves and by other astronomers. All future investigations must begin with selected readings of Burbidge and Burbidge to find out what is already known—or rather what was known in early 1967.

But *Quasi-stellar Objects* goes further than this. In addition to describing the observations, the Burbidges give a full account of the attempts of theoreticians to explain the phenomena. If the reader comes away with a confused impression, then this only shows how well the authors have done their work. No one can even be sure how to interpret the red-shifts. Are they cosmological? If so, the energy output of the typical quasar must be exceedingly great and its life-time perhaps as long as a million years. One would expect such an object to be quite large; on the other hand the rapid fluctuations in brightness indicate that in an important sense it has an underlying structure with a much smaller linear scale.

Are the red-shifts gravitational? Schmidt and Greenstein long ago showed that the emission spectra cannot arise on the outside of a body that is massive enough. The resultant gravitational red-shift z would be too small even for *3C* 273. To make the gravitational theory work one would have to postulate a structure of almost Byzantine complexity and of rather doubtful stability.

Are the red-shifts due to the Doppler effect in a set of local objects rapidly receding from the vicinity of our Galaxy? If so, who can imagine the dynamics of the explosion that sent off individual masses with speeds up to 0.82 c, but did not completely disrupt them? Further, where are the groups of quasars surrounding other galaxies, many of which should look to us much brighter than our own quasars and should show considerable blue-shifts? These are only a few of the arguments that the theoreticians have been involved in. The Burbidges give a very good account of them, even if sometimes they plead a little too much on behalf of their own favourite view.

The theoretical situation is indeed fluid, even turbulent. By the discovery of quasars the observers have shown the astrophysicists how far they are from understanding the Universe, just when they were beginning to feel a little too satisfied with their recent successes. Long may such observers continue to provide us with such surprises.

F. D. Kahn

SPECIAL RELATIVITY

Elements and Formulae of Special Relativity

(The Commonwealth and International Library of Science, Technology, Engineering and Liberal Studies: Physics Division.) By E. A. Guggenheim. Pp. x + 63. (Oxford, London and New York: Pergamon Press, 1967.) 21s. net; $4.50.

This book gives an account of the essentials of special relativity theory. Aberration, mechanics, hydrodynamics, electromagnetism are all covered at a simple level, as deductions from the Lorentz transformation, which is, however, not proved. The book is compact and will suit those who want a compendium of formulae but who do not wish to enquire too deeply into conceptual problems such as: why do we need a relativity of simultaneity, anyway? I have one reservation concerning the author's five and a half page chapter on relativistic thermodynamics. He treats it as if everything were cut and dried in this field. This is, however, misleading, and there is a body of opinion which would not accept all the formulae derived in this chapter.

P. T. Landsberg

POLYMER RELAXATIONS

Anelastic and Dielectric Effects in Polymeric Solids

By N. G. McCrum, B. E. Read and G. Williams. Pp. xv + 617. (London and New York: John Wiley and Sons, 1967.) 160s.

Were it not for the development of polymer science, through exploratory polymer chemistry in particular, the subject of viscoelasticity might have remained little more than an interesting and mathematically speculative curiosity. With the tremendous output of new products in recent decades, albeit often within, rather than from, the research laboratory, there has been a corresponding availability of materials which exhibit this phenomenon to a substantially marked degree and thereby allow for a more extensive study. Perhaps not surprisingly, from the touchstone of the varied demands of characterization, there has been at least a dualistic experimental approach to the subject of viscoelasticity, with some workers on the one hand concentrating more on mechanical features, whereas others have found dielectric properties of greater interest. This book makes a serious attempt to unify the two approaches, and even the nomenclature, by an integration of the relevant mechanical and dielectric aspects of linear viscoelasticity in such a way that it will be of interest not only to chemists and physicists but also to researchers in the fields of chemical, electrical and mechanical engineering.

Following an introductory chapter and a general one on the chemical and physical structure of polymeric solids, there are three, mainly theoretical, chapters on theories of the limiting moduli and the static dielectric constant, phenomenological theories of mechanical and dielectric relaxation, and molecular theories of relaxation including an account of secondary relaxations in solids Two useful chapters on experimental methods, mechanical and dielectric, conclude the first two-fifths of the book The rest is devoted to chapters on results obtained on individual classes of polymers, including methacrylate and related polymers, polyvinyl esters and related polymers; hydrocarbon polymers; halogen polymers, polyamides and polyurethanes, polyesters and polycarbonates, and, finally, oxide polymers A reference section containing more than 800 references in alphabetical sequence, many of recent origin, an author index and subject index complete the publication

The overall impression is of an authoritative account, agreeably printed and adequately supplemented with tables and figures—and not one spring or dashpot in sight—presented with a textual precision which permits a high content of detailed information Perhaps because of this, readers from one discipline may wish for a little elaboration on some parts which will be sufficient for those from another, and yet there will be no difficulty for the serious reader in seeking appropriate information, whether it be theoretical or experimental Here it should be pointed out, as the authors admit, that the subject matter is such that it will be of more immediate interest to the researcher rather than to, say, the practising engineer Nevertheless, herein lie many of the explanations for the often maligned properties of polymers which have been used in the wrong context, and to this end I feel that the book, or its contents, may profitably be reported outside the research laboratory This is a valuable publication and, although there may be one or two books it will not supplant, except in date, there are many accounts it will, and it is therefore strongly recommended both as a textbook and reference book for the serious reader and researcher in polymer science

R P SHELDON

LAYERED ROCKS

Layered Igneous Rocks

By L R Wager and G M Brown Pp xv+588 (Edinburgh and London . Oliver and Boyd, Ltd , 1968) 168*s* net

THE phenomenon of layering in igneous rocks has fascinated petrologists for many years and the name of Professor Wager has been associated with the subject, in particular with the Skaergaard Intrusion of East Greenland, for some thirty of them. It is fortunate that he had completed his contribution to this book before his sudden death in 1965 and that Professor Brown was able to carry the book to publication

The first part, written by Professor Wager, gives a very detailed account of the Skaergaard Intrusion which serves as a basis for comparison with the other layered complexes The account is systematic and commences with a general introduction to the characteristic features of the complex. Having done this, the minerals and the rocks composing the layered series are described. The chemistry is given meticulous coverage and equal attention is paid to the mechanism of differentiation of the layering While putting forward a theory, the authors do not agree that an explanation for one locality may necessarily satisfy another, and point out (page 338) that "No single theory is capable of explaining, for all layered intrusions, the origin of a feature such as rhythmic layering, because, despite overall similarities, the details differ from one intrusion to another"

The second part of the book, written by Professor Brown, is devoted to the other layered complexes of the world and in particular to the Bushveld, Stillwater and Rhum Intrusions In each case the treatment is the same, which makes comparison easy The form of the intrusion is described together with an account of its minerals present, the principal subdivisions of the intrusions are discussed and finally the crystal history is given In the case of the Bushveld, this is probably the most up to date general account since Hall's memoir of 1924 In all cases reference is made back to Skaergaard and points of similarity and dissimilarity are noted

Other types of basic layered intrusions described include the Cuillins of Skye, Kap Edvard Holm, East Greenland, Duluth, Minnesota, and the Great Dyke of Southern Rhodesia Described in less detail are twenty-nine smaller layered and fractionated intrusions, which are grouped by continents They include Ardnamurchan, the Lizard and Dawros from the British Isles, several examples from North America and Africa and three from Russia A short chapter is included on Differentiated Sills and there is also one dealing with layering in syenites and granites

This is a very comprehensive work—a compendium of layered intrusions in fact—which has been brought together in one volume for the first time The detail is such that it will be of most use to the advanced student and postgraduate, although students of even first year level may derive benefit from reading the first and last chapters on general aspects of layering It will be, and deserves to be, a classic textbook and it is a fitting tribute to Professor Wager's work.

J R V BROOKS

CELLS IN PAPERBACK

The Cellular Role of Macromolecules

(Series in Undergraduate Biology, Vol 2) By P H Jellinck Pp 117 (Glenview, Ill Scott, Foresman and Company, 1967) $2 25

THERE have been considerable changes in the teaching of biology recently, both at school and in the university, and there is a demand for suitable books particularly at the elementary level Publishers have met this need with textbooks of wide coverage and uneven quality, which are often characterized by redundant illustration There has also been a tendency for the production of paperback series which, while certainly no cheaper in aggregate, allow individual selections A narrower coverage also provides the opportunity for two essential features of any elementary monograph which is to interest and educate a student· an informed selection from the vast amount of material available, and a coherent view of the subject by the author

These desirable but elusive features are not always found in every volume of a series "The cellular role of macromolecules" is a large subject and may be difficult to cover adequately, but this book makes the attempt It begins with the description of various cells, then covers dynamic aspects of biological systems, before proceeding to a discussion of intermediary metabolism, biosynthesis and regulatory mechanisms.

Unfortunately it is not always very accurate For example, Gurdon's work on nuclear transplantation indicates a position very different from that of Briggs's and King's Transcription of RNA from one strand only of the DNA double helix clearly was not first shown from the poly dAT experiment quoted, nor does the evidence quoted show that transcription occurs "within the minor groove" of the DNA helix.

The book is probably the better for not being lavishly illustrated, although the whole page diagram of the reactions involved in lipid biosynthesis would not be very clear to an elementary student and certainly fails to compensate for the two short paragraphs on the subject Holley's work on transfer-RNA sequence is mentioned, but no comment is made on the secondary structure, with which it is compatible, the hairpin configuration is still discussed and illustrated

There are liberal quotations from many research workers, which may, as the author hopes, illustrate their contribution and philosophy, unfortunately they often punctuate the narrative flow and sometimes illustrate a turgid style Students may like to read these extracts and it is certainly helpful to mention the authors of various experiments, although I am puzzled by the subtle gradations which have decreed that some have Christian names, others initials and a few neither

This book does not supersede other similar paperbacks in this well-publicized field, despite several useful features.

P M B. WALKER

BIOLOGICAL PROBLEMS

Problems in Quantitative Biology

(Biological Science Texts) By J F. Eggleston Pp ix+226 (London The English Universities Press, Ltd, 1968) 22*s* 6*d*

THIS collection of numerical examples is intended to promote the teaching of biology as an exact science by providing exercises which give sixth form and first year university students experience in handling quantitative biological information, and help them to apply mathematical skills and assess the error and degree of significance involved. It might in some ways be regarded as an English counterpart of Joseph Schwab's *Invitations to Enquiry*

The book is organized in two sections. The first part comprises eight groups of analytical and numerical problems concerning physiological processes in plants and animals These groups deal severally with respiration and gaseous exchange; photosynthesis, water relations of animals and plants; ion uptake and loss in animals and plants, muscle and skeletal physiology, kidney and excretion; and statistics and genetics The second part, printed on distinguishing green paper and coded to correlate easily with the first part, claims to give a detailed consideration of the problems posed in the first part, together with their solutions To a professional mathematician the explanations might appear somewhat imprecise and inadequate

It is a truism that the quality of learning is determined by the quality of the teacher, certainly the educational use of this book calls for knowledge, skill and discrimination of a high order on the teacher's part It would be his task to select the problems appropriate to his pupils' sophistication both in biological concepts, facts and principles and in mathematical expertise, unless the text were to provide merely a collection of arid exercises Such a concentration of examples might well daunt those who take a more broadly humanistic view of the biological sciences than is at present fashionable, though the insufficiently numerate biology teacher might well find some reassurance in the second part of the book

There is certainly wide variety in the problems posed and this gives a helpful idea of the many aspects of biology which lend themselves to numerical treatment, nevertheless, mathematical problems should come into biology only if they elucidate a particular aspect of the subject Too often these problems seem artificial, thought up to involve some mathematical skill or physico-chemical consideration

Far from "spreading alarm and despondency" as the author fears, the introduction of material from original papers and advanced texts is a welcome and redeeming feature of the book It is certainly in accord with the current demand for relevance at all educational levels Unfortunately, the text lacks documentation and, if the author's hope that pupils will be stimulated to refer to reference books is to be fulfilled, an adequate bibliography is essential

Mathematics in the forms suggested by this book can indeed be a most useful precision tool for occasional use by a knowledgeable and discriminating practitioner, but as a "weapon in his armoury" the average teacher might well find such a concentrated device as this rather dangerously two-edged

Problems in Quantitative Biology should be regarded with caution as a teacher's reference book rather than adopted unreservedly as a student's text

E J VINNICOMBE

GENETICS REVIEWED

Annual Review of Genetics

Vol. 1. Edited by Herschel L Roman in association with Laurence M. Sandler and Gunther S Stent Pp. 334 (Palo Alto, California Annual Reviews, Inc, 1967) n p

THIS volume inaugurates a new member of the Annual Reviews series The usual two questions arise is it required, and if so, is it good? For once the answers can both be in the affirmative. Though most first issues manage to be good, this is exceptionally so The quality and composition of the editorial committee—Crow, Luria, Owen, Rhoades, Roman and Tatum—promise that the standard will continue H L Roman's editorship, in association with L M Sandler and G S Stent, is further guarantee

Genetics has at last permeated the whole of biology. Often unaware, now every biologist "does" some genetics The result is that those more primarily interested in the genetic aspects of any one problem are faced with the difficulty of scattered literature An *Annual Review of Genetics* is required to make this task easier

The first issue covers both highly specialized and more general topics Picking and choosing the chapters on "Human Genetics" by H E Sutton and "Population Genetics" by R C. Lewontin stress the generality of balanced polymorphism from man to *Drosophila* A masterly article by C Yanofsky reviews the five principal sources of evidence—two from bacteriophage and three from *Escherichia coli*—which have demonstrated the co-linearity between the nucleotide sequence of a gene and the amino-acid sequence of the polypeptide chain encoded in that gene S Emerson, in "Fungal Genetics", stresses the unique contribution of tetrad analysis to the investigation of the mechanisms of recombination As to "Developmental Genetics", H Ursprung stresses the change from the analysis of developmental pathways disrupted in mutants to that of sequential activity of genes in terms of messenger production

Those mentioned are only five of the thirteen review articles of this volume, all of which are valuable

G PONTECORVO

TAXONOMY OF PLANTS

Plant Variation and Classification

By Ritchie C. Bell (Fundamentals of Botany Series) Pp vi+135 (London Macmillan and Co, Ltd, 1967) 12*s* 6*d*

THIS is a typical "curate's egg" book, the sections on variation are very well done, while those on classification are weak in a number of places It suffers all the way through, also, by leaning too heavily on theoretical examples where a little searching through the literature would have revealed actual ones of much greater interest and value to the student

After an introductory chapter on variation and classification the author goes on to discuss nomenclature and keys, this chapter is reasonably well done, but at least seven errors occur in Table 2–1, where the translations of certain specific epithets are given

The historical chapter on botanical classification is interesting and of considerable value until a discussion of phenetic and phylogenetic classifications is embarked on Here, the author is led into serious errors, for example (page 36) "In the phenetic system, the arrangement of the taxa of plants according to their relative evolutionary position is made on the basis of the apparent relationships observed among available plants or plant materials" This is far from the truth, for the whole purpose of a phenetic system is to classify on the basis of observed characters, without any reference to evolutionary position

On the other hand, the fourth and fifth chapters are well reasoned and clearly written The fourth chapter deals with variation patterns, isolating mechanisms, aneuploidy and polyploidy. The fifth chapter describes the sources of variation, clearly differentiating phenotypic from genotypic variation and dealing well with each

Taxonomic characters are listed in the sixth chapter, but the author has not really been allowed enough space to do justice to these, especially to the newer techniques of chemotaxonomy and serotaxonomy, while studies on fine structure are not mentioned at all The seventh chapter deals with the evaluation and presentation of data and mentions hybrid indices, polygonal graphs and scatter diagrams Brief notes on numerical taxonomy are also included.

Finally, the eighth chapter gives short descriptions, illustrated by drawings and diagrams of twenty-five flowering plant families, with an average of one family per page These are quite well presented, though of course not much can be said about each family in such a short space and only the plants thought of as "typical" can be mentioned at all Incidentally, the so-called angiosperm classification on page 96, modified from that of Bessey, is not really a classification but a phylogenetic tree, and as such might be rather confusing to the student, for whom this book is intended

The suggestions for further reading are far ranging in subject, but of the thirty-four references to books (excluding state floras) only six were published outside the United States, while only one of the eleven periodicals is a non-American one There is no bibliography as such, even though the text has numerous references to authors and dates of publication

No doubt the author was strictly limited by the size of this book, which forms part of a series, and for that reason could not hope to go into greater detail in all the aspects of taxonomy he has tried to cover It would surely have been better, however, to omit the descriptions of the twenty-five families in the eighth chapter altogether and to have used the space so provided to enlarge other sections The chemotaxonomy, serotaxonomy and taxometrics sections would well repay expansion and it would be valuable to provide more actual examples of the points described, and surely, in a book of this sort, species concepts ought to be discussed or at least receive passing mention

J G HAWKES

PRODUCTIVITY OF FORESTS

Methods for Estimating the Primary Production of Forests

By P J Newbould. (International Biological Programme Handbook No 2) Pp viii + 62 (Oxford and Edinburgh Blackwell Scientific Publications, 1967) 7*s* 6*d*

THIS booklet consists of forty-seven pages of text and ten pages of references, it is intended to serve as a guide to the methods that may be recommended "to scientists who themselves do not think that they have better methods" (as E B Worthington says in the foreword) for the "general investigations of primary production" in woodlands which form part of the International Biological Programme, thus it concerns the annual yield of timber, branches, leaves, roots, and so on The recommendations are mostly sound, as indeed they ought to be in view of the many specialists who contributed to the original draft, and should be useful to the planner of investigations into such matters, provided that he makes full use of the references, heeds the many important but often inconspicuous warnings that are issued by Professor Newbould, and has a sound grasp of the statistical principles of sampling

Perhaps a fuller discussion of the relative importance of the various sources of error would have been welcome, and also a clearer relation of method to purpose, for example, tables which it is both legitimate and desirable to use when ascertaining relative yields of a single plot during successive periods of time may be grossly misleading if used for comparing the yields of plots in different environments Again, it is suggested that a period of between three and five years is probably adequate for measuring the growth of all-aged forest, it all depends on the purpose In Europe a period of ten years is no more adequate for giving a reliable estimate of mean increment than it would be for giving a reliable mean rainfall This, however, may be asking for too much in so small a space, and the critic is disarmed by the admission that the work could undoubtedly be improved, together with a request for suggestions to this end

Here, then, are some suggestions The old and well-tried method of measuring the volume of irregular branches by immersing them in water is worth mentioning. There is a large amount of information available on the pattern of density of wood in tree boles, and this should be consulted before sampling them for density, partition into sapwood and heartwood is not necessarily the best procedure Foresters, when measuring sample plots, usually measure the volume of bole and, sometimes, of branches, greater than some conventional "timber size" (in Britain 9 5 in girth), it would be useful if biologists, when measuring the amount of wood in a forest, measured separately from the rest the same components as those measured by local forest research departments, this would facilitate the comparison of foresters' and biologists' work, greatly to the advantage of biologists

EUSTACE W JONES

VEGETATION MAPPING

Vegetation Mapping

By A W. Kuchler Pp vi + 472 (New York The Ronald Press Company, 1967) $15

WITH few exceptions, mainly in Europe, mapping of vegetation has proceeded largely in isolation from other ecological activities This book will probably bring to the notice of many ecologists for the first time the amount and interest of the work that has been going on in this field It is therefore welcome in a broader context than is indicated by its ostensible purpose of providing a handbook and guide to the procedures and technicalities of producing vegetation maps

The author of this book is a leading practitioner of vegetation mapping, who is particularly well qualified to bring together the diverse literature of the subject He has succeeded in producing what will be a definitive guide to this field, at least in English speaking countries, for some time

The book opens with an interesting "Historical Sketch" of the development of vegetation cartography The second section of the book is concerned with "Some Basic Considerations" This is somewhat disappointing Before units of vegetation can be mapped, a clear conception of the nature of these units is necessary and one expects some discussion of the thorny problems that surround concepts of the plant community. These problems are scarcely mentioned and one looks in vain in the extensive bibliography for many of the names of those who have figured in discussion of them. Tansley, Clements and Curtis receive incidental mention in this connexion but without indication of the fundamental differences between their points of view, others, for example Gleason and Ramensky, are not mentioned at all. Classification is likewise treated rather superficially. The author rightly emphasizes that only two types of features are available as criteria in the classification of vegetation (as opposed to classification of sites)—structure and floristic composition—but there is little discussion of what aspects of the floristic composition should receive most weight and there is no consideration at all of the development of numerical techniques that has been such a prominent feature of phytosociology in the past decade.

The third section of the book deals with "Technical Aspects", covering such questions as choice of scale, use of aerial photographs, choice of colour and symbol, the lay-out of maps and accompanying texts, and so on. This section raises few points of fundamental controversy (though many will consider the relegation of "Boundaries and Transitions" to a technical aspect somewhat surprising). These technical aspects are clearly and interestingly presented and treated in a well-balanced manner.

The fourth, and longest, section deals with the practice of mapping in various conditions and according to various schools. This account will be invaluable both to those considering possible methods to use in vegetation mapping and to those concerned to make use of vegetation maps emanating from different schools.

The final section is concerned with "Application of Vegetation Maps". In addition to the use of vegetation maps as tools in ecological and geographical research, examples, actual or hypothetical, are given of their use as climatic records, in pedology and geology, agriculture, forestry, land management and planning, education, for commercial engineering and fiscal interests, and in relation to military activities. This is a most impressive list. If only a small proportion of the suggested potential uses is realized, there is indeed a strong case for extensive allocation of resources to vegetation mapping.

A bibliography of some 600 references is particularly valuable for its coverage of literature in French and German. There are few references after 1963.

In spite of the reservations indicated here, this is a valuable and timely book, although few will go all the way with the author in assigning a central role in the understanding of vegetation to vegetation mapping. The author is an enthusiast for his subject and his enthusiasm makes his book a pleasure to read, even when we may disagree with what he has to say. It is written in an easy and informal style and well produced, though the price, by European standards, seems rather high.

P. GREIG-SMITH

PARENTS ARE DIFFERENT

Influences on Parent Behavior

By Lois Meek Stolz. (Stanford Studies in Psychology.) Pp. viii + 355. (London: Tavistock Publications, Ltd., 1967.) 65s. net.

IT is well accepted that parents, even when social variables such as religion or social class are controlled, will vary considerably in their child-rearing behaviour. The author of this lengthy book is concerned to isolate some of the factors—either conscious or easily recalled since unconscious ones are inaccessible by social research—which may influence them.

Repeated interviews were carried out with both parents in thirty-nine families. Most fathers were interviewed by men and most mothers by women. Four main groups of influences were described: (1) values, that is goals, (2) beliefs, that is (*a*) instrumental (children obey their fathers because they respect them), or (*b*) descriptive (girls seem to like horses), (3) others—(*a*) past and present experiences, (*b*) communications, mass and personal, and (*c*) behavioural settings.

It might have been better, in view of the original assumption that families vary in spite of social homogeneity, to have selected a group who were similar in all major respects. Instead the author took pains to keep the group as disparate as she could. There are some suggestive findings here, but the work is based on too slight information to prove ultimately reliable. There is a great overlap of influences described which can only be assigned weighted importance with a much more selective approach and with a larger sample. The book is too long for easy reading and would benefit by good cutting and editing.

ANNETTE LAWSON

HANDBOOK REVISED

Handbook of Chemistry and Physics

A Ready-reference Book of Chemical and Physical Data. Editor-in-chief, Robert C. Weast. Forty-eighth edition. (Cleveland, Ohio: The Chemical Rubber Co.; Oxford: Blackwell Scientific Publications, 1967.) 170s.

THE *Handbook of Chemistry and Physics* has progressed a long way since its first appearance as a pocket edition in 1913. Now in the 48th version, the handbook has gained so many tables over the years that it might be more appropriately labelled "satchel sized", but it nevertheless remains true to its description of a "ready reference book of chemical and physical data".

Information is classed into one of six sections, which cover mathematical tables, elements and inorganic compounds, organic compounds, general chemical constants, general physical constants and miscellaneous. Nearly 2,000 pages provide more than 550 tables, seventeen of them new, and more than eleven revised. Information that has been included for the first time covers absolute viscosity of liquid sodium and potassium, constants for satellite geodesy, factors for conversion of $\log_{10}$ to $RT\log_e X$, infrared correlation, far infrared vibrational frequency correlation and characteristic frequencies between 700–300 cm^{-1}. New charts also give characteristic nuclear magnetic resonance spectral positions for hydrogen in organic molecules, ionization constants for deuterium oxide from 10° C to 50° C, heats of combustion, density and composition of sulphuric acid, thermal conductivity of certain metals, liquids and gases and solubility products. There is a supplementary table of diamagnetic susceptibilities of organic compounds, and a table, of particular interest to bearded scientists perhaps, of mechanical and physical properties of whiskers.

The rate at which scientific knowledge increases these days must give the editors of a handbook like this rather a headache, for now it must be more a question of what to leave out than what to put in, if the book is to remain a manageable size. It has been thought impossible to produce one volume to cater for the biological as well as the physical sciences, but although concentrating on the physical sciences the editors have been conscious of the growing interdisciplinary attitude in science, and have included tables that extend beyond the physical field. The mathematical section has been growing steadily over the years to keep pace with the growing complexity of modern chemistry and physics, largely at the suggestion of users of the handbook. A large editorial board is involved in its production, with Robert C. Weast as editor-in-chief, so the handbook ends up full of information for the scientists, by the scientists, giving a vast quantity for the money.

ELISABETH LEWIS

University News : Edinburgh

Professor J I G Cadogan, at present Purdie professor of chemistry in the University of St Andrews, has been appointed to the Forbes chair of organic chemistry on the retirement of Professor E Hirst

Announcements

The Council of the Edinburgh Geological Society has awarded the Clough Medal for the period 1967–68 to Dr A G MacGregor in recognition of his contributions to Scottish geology, particularly in the fields of volcanology, tectonics and metamorphism

The Paul Instrument Fund Committee, which is composed of representatives of the Royal Society, the Institute of Physics and the Physical Society and the Institution of Electrical Engineers, and was set up in 1945 "to receive applications from British subjects who are research workers in Great Britain for grants for the design, construction and maintenance of novel, unusual or much improved types of physical instruments and apparatus for investigations in pure or applied physical science", has made the following grants

£2,000 to *Dr A P Anderson*, lecturer in the department of electronic and electrical engineering in the University of Sheffield, for the construction of an instrument for the measurement of energy in laser beams, £1,500 to *Dr W J Jones*, demonstrator in the department of physical chemistry, University of Cambridge, for the construction of a spectrometer employing frequency selective intensity modulation, £1,830 to *Mr A R Luxmoore*, division of civil engineering, University College of Swansea, for continuation of the construction of a 'Moiré-scope' for which he received a grant of £5,000 in November 1965 and £1,980 in June 1967, £6,250 to *Professor J D McGee*, professor of applied physics at the Imperial College of Science and Technology in the University of London, for continuation of his work on the development of a photoelectronic image device for time images for which in December 1964 he received a grant of £8,100 over three years, £4,000 to *Dr K I Mayne*, senior lecturer in the department of natural philosophy in the University of Edinburgh, for the construction of a polarized electron source.

Wolfson Foundation Grants for Technological Projects On October 14, 1967, the Wolfson Foundation made public its decision to set aside, in principle, up to £500,000 a year over the next five years to support large projects at universities in fields of applied science which, in the judgment of the trustees, would be most likely to improve the economic position of the United Kingdom and help the modernization of British industry Subsequently all universities and colleges of technology were informed of this decision The foundation now announces that applications in support of projects which conform to its intentions should be sent, in appropriate detail, to the foundation offices (Universal House, 251 Tottenham Court Road, London, W1) by July 1, 1968 It is hoped that it will be possible to decide by early October which schemes the foundation will support Applications will be judged in competition with each other on the basis of their technical merits Favourable consideration will be given to projects which are linked to industry Applicants who feel they require information about the relevance of possible projects should get in touch with the director of the foundation

An experimental Information Centre on Intestinal Absorption has been set up at the University of Sheffield with a grant from the Office for Scientific and Technical Information (OSTI) The project, initiated by Professor D H Smyth, is a joint venture of the Department of Physiology and the Postgraduate School of Librarianship and Information Science (director, Mr W L Saunders) At present the centre has a staff of three A monthly bulletin of literature references with brief abstracts is produced The emphasis is on mechanisms of transport across the absorptive epithelium, a field in which Professor Smyth's department is very active and has much experience References are collected both by conventional methods and by the computer services *ASCA*, *CBAC*, *Chemical Titles* and *MEDLARS* Author and subject indexes are produced using a computer in conjunction with offset lithography The aims of the project are 1, to investigate information needs of workers in this field and services already available, 2, to indicate ways in which a centre of this kind can provide improved information services, 3, to investigate the benefit, to users, of the association of the centre with an active group of research workers, 4, research and development in methods of information handling

During 1968 the service will be free, users will be asked to help to improve the service by providing details of their information requirements Further details may be obtained from Mr J K Barkla, Biomedical Information Project, Department of Physiology, University of Sheffield

Meetings

Biological Semiconductors, April 1–3, University of Nottingham (Dr J B Finean, Department of Medical Biochemistry and Pharmacology, The University, PO Box 363, Birmingham 15)

Heavy Particle Collisions, April 1–3, Queen's University of Belfast (The Conference Secretary, The Institute of Physics and the Physical Society, 47 Belgrave Square, London SW1)

Business Information, April 8–9, University of Aston, Birmingham (The Education Officer, Aslib, 3 Belgrave Square, London SW1)

Some Aspects of Heterocyclic Sulphur Chemistry, April 9–10, University of Salford (Drs O Meth-Cohn and B Iddon, Department of Chemistry, University of Salford, Salford 5, Lancashire)

Spectroscopy, April 17–19, Brighton (The General Secretary, Institute of Petroleum, 61 New Cavendish Street, London W1)

Erratum In the introduction to the article "Multiphase Development of the Lunar Crater Tycho" by R G Strom and G Fielder (*Nature*, 217, 611, 1968) it was stated that Orbiter V landed on the Moon, which is, of course, wrong—the satellite orbited the Moon

CORRESPONDENCE

Inside Plants

Sir,—When I read a review such as that which you publish for *Plant Anatomy* (by Professor A Fahn) in *Nature* (216, 522, 1967), I realize how low the intellectual level is sinking and the disservice which is propagated It was a sad day when *Nature* forsook Wordsworth's advice*, for this meanness would never have been reached

Yours truly,

E. J H Corner

Botany School,
Downing Street,
Cambridge

**Nature* used to bear the legend "To the solid ground of Nature trusts the mind that builds for aye "

FORTHCOMING EVENTS

(*Meetings marked with an asterisk are open to the public*)

Monday, March 4

Institution of Electrical Engineers (at Savoy Place, London, WC2), at 10 a m —Colloquium on "Pulsed Code Modulation"

University of London (at the Royal Postgraduate Medical School, Du Cane Road, London, W12), at 4 p m —Professor R D Girdwood "Folic Acid Deficiency"

Institution of Civil Engineers (at Great George Street, Westminster, London, SW1), at 5 30 p m —Informal Discussion on "The Organization of the Port Planning Team and the Role of the Engineer", introduced by Mr J E G Palmer

Institution of Electrical Engineers (at Savoy Place, London, WC2), at 5 30 p m —Discussion Meeting on "The Need or Otherwise for Suppression of Harmonics Generated by Convertor Equipment" opened by Mr H J Sheppard

University of London (at the Royal Free Hospital School of Medicine, 8 Hunter Street, London, WC1), at 5 30 p m —Docent Annica Dahlstrom (Stockholm and Goteborg) "Monoamine-containing Neurones in Mammals I Monoamine-containing Neurones in Mammals as Studied by Fluorescence Microscopy" *

Institution of Mechanical Engineers, Applied Mechanics Group (at 1 Birdcage Walk Westminster, London, SW1), at 6 p m —Discussion Meeting on "Designing Components Subjected to High Surface Pressure"

Society of Engineers (at the Geological Society, Burlington House, Piccadilly, London, W1), at 6 p m —Mr F W Hyde "Progress in Radio Astronomy"

Society of Chemical Industry, London Section (joint meeting with the Chemical Engineering and Heavy Organic Chemicals Groups, at 14 Belgrave Square, London, SW1), at 6 30 p m —Sir Kenneth Hutchison, CBE "New Sources of Natural Gas for Britain" (Jubilee Memorial Lecture)

Tuesday, March 5

Institution of Electronic and Radio Engineers, Joint IEE/IERE Computer Groups (at the Institution of Electrical Engineers, Savoy Place, London WC2), at 10 a m —Colloquium on "Large Scale Integration"

Chemical Society, Chemical Crystallography Group (at the Geological Society, Burlington House Piccadilly, London, W1), at 2 p m —Discussion Meeting on "Penta-Co-Ordination"

Institution of Civil Engineers (at Great George Street, Westminster, London, SW1), at 5 30 p m —Mr P H Steel "The Bristol Regional Foul Water Drainage Scheme"

Institution of Electrical Engineers (joint meeting with the Automatic Control Group of the I Mech E , and the Institute of Measurement and Control, at Savoy Place, London, WC2), at 5 30 p m —Mr I V Idelson "Towards Control Theory in Warehousing"

University of London (at the Royal Free Hospital School of Medicine, 8 Hunter Street, London, WC1), at 5 30 p m —Docent Annica Dahlstrom "The Monoamine-containing Neurones in Mammals II Distribution and Turnover of Noradrenaline and Storage Granules in Sympathetic Adrenergic Neurones" *

Institution of Mechanical Engineers, Thermodynamics and Fluid Mechanics Group (at 1 Birdcage Walk, Westminster, London, SW1), at 6 p m —Discussion meeting on "How Shall We Use North Sea Gas ?"

Wednesday, March 6

Royal Institution, History of Science Discussion Group (at 21 Albemarle Street, London W1) at 1 p m —Dr N E Butcher "Geology as an Applied Science in the Nineteenth Century" *

Colour Group (Great Britain) (in the Physics Department, Imperial College, London, SW7) at 2 30 p m —Meeting on "Thin Films" Dr A Thetford "Interference Filters—Theory", Mr H A Macleod "Interference Filters—Manufacture"

Institute of Petroleum (at 61 New Cavendish Street, London, W1), at 5 30 p m —Mr D W N Dolbear "Vocational Training for Graduates in Exploration"

University of London (at the Institute of Child Health, Guilford Street, London, WC1), at 5 30 p m —Dr C L Cope "Steroids and Stress" (Last of three lectures on "The Scientific Basis of Dentistry" organized by the British Postgraduate Medical Federation)*

University of London (at the Institute of Archaeology, 31–34 Gordon Square, London, WC1) at 6 p m —Mr B Greenhill "Sources of Maritime Archaeology—The Building of Schooners" *

Society for Analytical Chemistry, Microchemical Methods Group (at "The Feathers", Tudor Street, London, EC4), at 6 30 p m —Discussion Meeting on "Automatic C H N Analysers", introduced by Mr T R F W Fennell

Society of Environmental Engineers, Packaging Group (at the Euston Tavern, 73 Euston Road, London, NW1), at 6 30 p m —Mr A Thompson "Tailoring Foams for Package Cushioning'

Pharmaceutical Society of Great Britain (at 17 Bloomsbury Square, London, WC1) at 7 p m —Professor Maurice Leclerc (Faculte de Pharmacie, Paris) ' Therapeutic Use of Anticoagulants"

Thursday, March 7

University of London (in the Anatomy Theatre, University College London, Gower Street, London, WC1), at 1 20 p m —Dr O C J Lippold "Art in Scientific Research" *

Royal Society (at 6 Carlton House Terrace, London, SW1) at 4 30 p m —Dr G D H Bell FRS "Plant Breeding for Crop Improvement in Britain —Methods, Achievements and Objectives" (Review Lecture)

Institution of Civil Engineers, Education and Training Group (at Great George Street, Westminster, London, SW1), at 5 30 p m —Informal Discussion on "The Higher National Diploma in Civil Engineering", introduced by Mr R J Ashby

Institution of Electrical Engineers (at Savoy Place, London, WC2), at 5 30 p m —Discussion meeting on "Research in the Electricity Supply Industry" opened by Dr L Rotherham, FRS

University of London (in Mechanical Engineering Lecture Theatre A, Imperial College, London, SW7), at 5 30 p m —Professor A Gansser (Zurich) "Evolution of the Himalayas" (further lecture on March 8) *

Institute of Refrigeration (at the National College for Heating, Ventilating, Refrigeration and Fan Engineering, Southwark Bridge Road, London SE1), at 6 p m —Mr J Templeton and Mr J H Merritt "Tests on Flexible Connections for Vertical Plate Freezers"

Institution of Electronic and Radio Engineers, Communication Group (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, WC1), at 6 p m —Mr W D Benson and Mr B Buckingham "Integrated Circuits for Radio Receivers"

Institution of Mechanical Engineers, Steam Plant Group (at 1 Birdcage Walk, Westminster, London, SW1), at 6 p m —Discussion meeting on "Steam Generation from Refuse"

Friday, March 8

Society for Water Treatment and Examination (at the College of Preceptors, 2 and 3 Bloomsbury Square, London, WC1), at 9 30 a m —Technical Sessions of the Sixteenth Annual General Meeting

Royal Institution, Photochemistry Discussion Group (at 21 Albemarle Street, London, W1), at 1 p m —Dr A D Osborne "Transient Species in the Flash Photolysis of Some Dyes" *

Institution of Electrical Engineers, History of Technology Group (at Savoy Place, London, WC2), at 5 30 p m —Mr R J Halsey "British Contributions to Telecommunication"

Royal Institution (at 21 Albemarle Street, London, W1), at 9 p m —Mr C Maxwell Cade "Seeing by Heat-Waves"

Saturday, March 9

Inner London Education Authority (at the Horniman Museum, London Road, Forest Hill, London, SE23), at 3 30 p m —Mr Oliver S. Turner "The Canals of London" *

Monday, March 11

Society of Chemical Industry, Microbiology Group (joint meeting with the Colloid and Surface Chemistry Group, at 14 Belgrave Square, London, SW1), at 5 30 p m —Dr D A Haydon "Some Recent Developments in the Study of Biomolecular Lipid Films"

Institution of Electrical Engineers (joint meeting with the Automatic Control Group of the I Mech E , and the Institute of Marine Engineers, at 1 Birdcage Walk, Westminster, London, SW1), at 6 p m —Meeting on "Roll Stabilisation and Auto Pilots in Marine Engineering Application"

Monday, March 11—Thursday, March 14

Institute of Metals (at Church House, Great Smith Street, London, SW1) —Spring Meeting

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Senior Lecturer (with research interests in some branch of solid mechanics) in Applied Mathematics—The Registrar, University of Strathclyde George Street, Glasgow, C1 (March 9)

Lecturer or Assistant Lecturer (graduate) in Botany—The Secretary, Bedford College (University of London), Regent's Park, London, NW1 (March 11)

Lecturer or Assistant Lecturer (preferably candidate working in the fields of helicopter dynamics or mathematical physics) in Applied Mathematics—The Registrar and Secretary, The University, Leeds, 2, quoting Ref No 68/21/3 (March 11)

Lecturer in Palaeontology and Stratigraphy at the University of Durban, Natal—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (South Africa and London, March 15)

Lecturers in Applied Mathematics in the fields of continuum mechanics, control theory or other branches of mathematics of practical importance—The Registrar, University of Warwick, Coventry, CV4 7AL, Warwickshire (March 15)

Lecturer or Assistant Lecturer (with a special interest in developmental problems) in Plant Physiology—The Registrar, University College of Wales, Aberystwyth (March 18)

Lecturer in Mechanical Engineering—The Secretary, The University, Dundee Scotland (March 21)

Assistant Experimental Officer (with a degree in chemistry or an equivalent qualification) to supervise chemical analyses and to take part in research projects related to the chemical aspects of quality in agricultural crops—The Secretary, Plant Breeding Institute, Maris Lane, Trumpington, Cambridge (March 23)

Research Demonstrators (with qualifications in microbiology, bacteriology, biochemistry or related subjects) in the Department of Microbiology—The Assistant Bursar (Personnel), University of Reading, Reading, Berks (March 25)

Lecturer in Botany—The Secretary, University College, Cork, Republic of Ireland (March 29)

University Lecturer (with a good degree in an anthropological subject with sound training experience and teaching experience in material culture, including technology) in Ethnology in the Department of Ethnology

AND PREHISTORY—The Secretary of Faculties, University Registry, Broad Street, Oxford (March 30)

SENIOR LECTURER or LECTURER in the DEPARTMENT OF VETERINARY MEDICINE, University of Ibadan, Nigeria—The Inter-University Council, 33 Bedford Place, London, WC1 (April 1)

ASSISTANT PROFESSORS (3) in the DEPARTMENT OF GEOLOGY Haile Sellassie I University, Ethiopia—The Inter-University Council, 33 Bedford Place, London, WC1 (April 15)

CHAIR OF MEDICAL PROTOZOOLOGY at the London School of Hygiene and Tropical Medicine—The Academic Registrar, University of London, Senate House, London, WC1 (April 30)

CHAIR OF TROPICAL HYGIENE and the London School of Hygiene and Tropical Medicine—The Academic Registrar, University of London, Senate House, London, WC1 (April 30)

SECOND CHAIR OF CHEMISTRY—The Secretary, University of Lancaster, University House, Bailrigg, Lancaster (April 30)

ASSISTANT PROFESSOR (biochemist or plant physiologist) in the Division of Plant Physiology and Biochemistry, Faculty of Agriculture—Head, Department of Plant Science, University of Alberta, Edmonton, Alberta, Canada

CURATORIAL ASSISTANT (with a BSc or MSc in earth sciences, and preferably some artistic talent) to act as Museum Guide for school groups, and to assist in organization, care and display of rock mineral and fossil collections—Chairman, Museum Committee, Department of Geology, University of Alberta, Edmonton, Alberta, Canada

READERS, SENIOR LECTURERS, LECTURERS IN PHYSICS, CHEMISTRY, BIOLOGY or MATHEMATICS, with opportunity for Professorship—The President, Hacettepe University, Ankara, Turkey

RESEARCH ASSISTANT (preferably with experience in one of the following fields gas dynamics, electrical discharges, combustion) to study electrogasdynamic power generation—Dr J Lawton, Department of Clerical Engineering and Chemical Technology, Imperial College, London, SW7

SENIOR LECTURER, LECTURER or ASSISTANT LECTURER IN ASTRONOMY—The Academic Registrar, Hatfield College of Technology, Hatfield, Herts

HOW TO BUY NATURE

Volumes start in January, April, July and October, but subscriptions may begin with any issue

The direct postal price per subscription for one or two copies of NATURE each week is

***12 MONTHS** (52 issues and 4 indexes)

Great Britain and Eire		**£14 0 0** each
United States of America	(by air freight)	**$48** each
Canada	(by air freight)	**$52** each
Elsewhere overseas by surface mail		**£14 0 0** each

(Charge for delivery by air mail on application)
*Shorter periods *pro rata* (Minimum three months)

MULTIPLE SUBSCRIPTIONS

For subscribers who take more than two copies of NATURE each week these reduced annual rates are offered

12 MONTHS (52 issues and 4 indexes)

Number of Copies	*G B & Eire*	*U S A (by air freight)*	*Canada (by air freight)*	*Elsewhere (surface mail)*
	Each	*Each*	*Each*	*Each*
3–5	**£13 10 0**	**$46 50**	**$50 50**	**£13.10 0**
6–11	**£12 15 0**	**$44 50**	**$48.30**	**£12 15 0**
12 or more	**£12 0 0**	**$42 50**	**$46 00**	**£12 0 0**

Multiple subscriptions must run concurrently Every copy will be posted separately, and for speed of delivery each subscription can be addressed to a different individual, or department at the same address (ZIP essential for U S A)

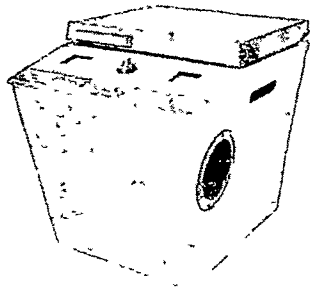
"JANETZKI"

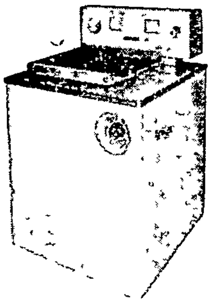
MEANS QUALITY

IN CENTRIFUGES



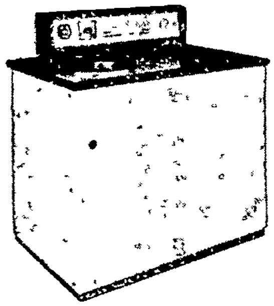
Bench Types T23 and T24

The largest of the Janetzki Bench Models Superbly engineered twin machines covering a range in speed up to 16,000 r p m in centrifugal force up to 21,500g and in capacity up to 8× 100 ml



Refrigerated Types K23/4

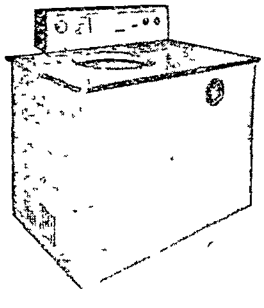
Performance and Rotors as T23 and 24 But the refrigerated versions K23 and K24 give, in addition, temperatures down to —8° C For a very modest cost, 90% of the centrifuging requirements of the average laboratory can be covered Wide selection of rotors and adapters available Naturally the machines have such features as electric speed control, brake, safety lock and revolution counter They are outstanding in workmanship and finish



Large Types S60 and K60

Swing out rotors up to 4× 1,000 ml Angle rotors up to 8×250 ml or 6×500 ml Gravitational force up to 4,800g with high speed unit 22,300g Refrigerated version K60

Down to —22° C



New and Unique Vac20

Fully automatic Programme controlled
High capacity-High speed 6×500 ml —69,500 max g For the concentration of culture liquids, bacteria, virus, enzyme preparations, production of serum, vaccines, enzymes, nucleic acids, proteohormones and other antibiotic substances Preparation and purification of organic high polymers

Elsevier's journal for papers at the forefront of research on protein fine structure and conformation

BIOCHIMICA ET BIOPHYSICA ACTA

PROTEIN STRUCTURE

Isolation and covalent structure - solution properties - subunit dissociation and interaction - immunochemistry - probing of active sites - magnetic and spectroscopic analysis of metallo- and pigment-bearing proteins - electron microscopy of proteins

A sample of forthcoming papers

A hexapeptide from pig neurohypophysis - A V Schally & J F Barrett (New Orleans, USA)

Die Aminosauresequenz des Mureins von *M lacticum* - K.H Schleifer, R Plapp & O Kandler (München, Germany)

Reversible acetoacetylation of proteins - A Marzotto, P. Pajetta, L Galzigna & E Scoffone (Padova, Italy)

α_1-acid glycoprotein variants - K Schmid, T Okuyama & H Kaufmann (Boston, USA)

Amino acid content of hyaluronic acid - D A Swann (Boston, USA)

Chemical characterization of $\mathrm{Hb}_{\mathrm{Mexico}}$ and $\mathrm{Hb}_{\mathrm{Chiapas}}$ - R T Jones, B. Brimhall & R Lisker (Portland, USA)

The associating subunit of α_{s1}-casein - D G Schmidt & B W Van Markwijk (Ede, Netherlands)

Molecular weight and subunit structure of human serum high-density lipoprotein after chemical modification by succinic anhydride - A. Scanu, W. Reader & C Edelstein (Chicago, USA)

ESR of four human hemoglobins - G Bemski & R L Nagel (New York. USA)

Proton magnetic relaxation of lamprey hemoglobins - S Mančić & N M. Rumen (Philadelphia, USA)

The interaction of troponin with F-actin and its abolition by tropomyosin - W Drabikowski & Y Nonomura (Tokyo, Japan)

Ordered as a part subscription to BBA, a personal or departmental 'Protein Structure' costs US$54.00

Subscription details for 1968
BBA-Protein Structure Vols P4, P5 & P6 9 issues, total price US$54.00, Dfl 195 00 (post-free) Airmail surcharge for USA and Canada US$0 90 (total)

Back volumes (1967)
BBA-Protein Structure Vols P1, P2 & P3 (*Biochim. Biophys Acta,* Vols. 133, 140 & 147) Total US$60 00 or Dfl 216 00 (post-free)

APPOINTMENTS VACANT

UNIVERSITY OF EAST AFRICA
UNIVERSITY COLLEGE, NAIROBI

Applications are invited for the following appointments

(a) Senior Lectureship in ARCHITECTURE Applicants should offer as their special fields of interest either (i) Physics of Human Environment or (ii) Advanced Building Technology and Building Design Management

(b) Lectureship in ARCHITECTURE Appointee required to organize courses in fundamental draughtsmanship

Appointees to (a) and (b) required to take charge of one year of the course and set and supervise studio programmes

(c) Lectureship in INORGANIC or ANALYTICAL CHEMISTRY

(d) Senior Lectureship in GEOGRAPHY

(e) Lectureship in GEOLOGY Appointee will teach branches of Geophysics

(f) Lectureship in MECHANICAL ENGINEERING Candidates should possess good academic qualifications with industrial, research or teaching experience Special interest and experience should be in the fields of Mechanical Design, Production Engineering or Dynamics

Salary scales Senior Lecturer, £EA1 950 to £EA2 615 per annum, Lecturer, £EA1 350 to £EA2 230 per annum (one EA shilling=1s 2d sterling) Salary supplemented in appropriate cases under British Expatriates Supplementation Scheme in range £345 to £505 per annum (sterling) Expatriates are usually appointed on two-year tours F.S S U Subsidised accommodation Passages for appointee and family (up to five adult passages) on appointment and termination

Detailed applications (six copies) naming three referees by March 31, 1968, to Inter-University Council, 33 Bedford Place London, W C 1, from whom particulars are available (910)

UNITED BRISTOL HOSPITALS
BRISTOL ROYAL INFIRMARY
RESEARCH ASSISTANT IN HOSPITAL BIOCHEMISTRY

Applications are invited from science graduates (or those expecting to graduate in 1968) for the post of Research Assistant in the chemical pathology section of the clinical pathological laboratory of the United Bristol Hospitals The work will involve development of methods of saturation analysis and in particular the radioimmunoassay of hormones in the blood The salary will be according to qualifications and experience within the scale for basic grade hospital biochemists (from £963 for first- or second-class honours graduates or £855 for others up to £1 210) Opportunity for taking higher degree

Applications with the names of two referees to Dr K G McGowan, Department of Clinical Pathology, Royal Infirmary, Bristol, 2 (882)

SOUTHAMPTON GENERAL HOSPITAL
(586 beds)
TREMONA ROAD SHIRLEY,
SOUTHAMPTON S09 4XY

Science Graduate or **Medical Laboratory Technician** required for new Endocrine Laboratory within a Group Pathology organization Work in the radioimmunoassay of peptide hormones particularly parathyroid hormone and in associated research Previous practical experience desirable Envisaged grading is that of Basic Biochemist or Senior II Medical Laboratory Technician

Further information obtainable from Dr R M Buckle Department of Endocrinology Applications to the Hospital Secretary at the above address (879)

CSIRO BIOCHEMIST
AUSTRALIA
DIVISION OF PLANT INDUSTRY
MICROBIOLOGY SECTION

GENERAL The Division of Plant Industry of the Commonwealth Scientific and Industrial Research Organization which has regional laboratories and experiment stations in many parts of Australia and a large staff of experimental and research scientists, carries out research in a wide range of plant sciences on problems fundamental to agricultural production The research staff of the Microbiology Section of the Division is working in a variety of fields including physiology and biochemistry of disease resistance, biochemistry of nitrogen fixation, serology and immunochemistry of *Rhizobium* species and biochemistry of spore germination in fungi The Section has a wide range of equipment available and has access to CERES, the Division's Phytotron

DUTIES The appointee will join a research group investigating the physiological and biochemical basis of disease resistance in plants using model host-pathogen systems He will be expected to undertake a research programme investigating the underlying biochemical and enzymological reactions in plants which, in response to fungal infection and to certain fungal metabolites, lead to the production in the plant of antifungal defence compounds (phytoalexins) Opportunities exist for independent and team research both with this group and with other biochemists and molecular biologists in the Division

QUALIFICATIONS Applicants should have a Ph D degree, or relevant postgraduate research experience of equivalent standard and duration, supported by satisfactory evidence of research ability Prior experience in the metabolism and regulatory mechanisms of plants would be an advantage

SALARY Depending upon qualifications and experience, the appointment will be made within the salary ranges of Research Scientist, $A5,250–$A6,622 p a , or Senior Research Scientist, $A6,892–$A7,974 p a Salary rates for women are $A428 p a less than the corresponding rates for men

CONDITIONS The duration of the appointment will be determined in consultation with the successful candidate, some applicants may prefer a fixed term appointment of three years

Fares paid for the appointee and his dependent family If the appointee is at present domiciled outside Australia, return fares will be paid at the conclusion of a fixed term appointment Applications (quoting Appointment No 130/896), and stating full name, place, date and year of birth, nationality, marital status, present employment, details of qualifications and experience, together with the names of not more than four persons acquainted with the applicant's academic and professional standing, should reach —

Mr R F Turnbull,
Chief Scientific Liaison Officer,
Australian Scientific Liaison Office,
Africa House Kingsway,
LONDON, W C 2 by the 29th March, 1968

(906)

UNIVERSITY OF GUELPH

The University of Guelph wishes to appoint a

DIRECTOR
of the Institute of Biomedical Research

The Institute is now in the planning stage, and the early appointment of the Director is desirable so that he can participate in all aspects of planning The Institute, under the administration of the University of Guelph is intended to serve the biological and medical sciences at Guelph and at the other Universities in Ontario

The Institute will provide facilities for the production of laboratory animals and for an active educational programme in laboratory animal medicine and technology The director will be expected to initiate and stimulate research and educational programmes in comparative medicine

The Director will be a member of the faculty of the University of Guelph with an academic appointment in an appropriate department

Applicants must have advanced training in biological and medical science and, preferably, considerable experience in comparative medicine

Applications and enquiries should be addressed to the **Associate Dean (Research), Ontario Veterinary College, University of Guelph, Guelph, Ontario, Canada.**

(760)

AGRICULTURE

General agriculturists and agricultural specialists of many kinds are frequently required in the effort to match the large demand from the developing countries The vacancies advertised below are a selection from the many openings which exist now While they are being filled, other vacancies are arising Salaries within the ranges quoted are assessed on qualifications and experience, and the terms of most appointments include free or subsidised accommodation, education grants, family passages, good leave on full pay, etc Most appointments are limited to nationals of the United Kingdom or the Republic of Ireland who are normally resident in those countries

AFGHANISTAN

Cotton Adviser RC 213/2/02

Duties To advise on the development and expansion of cotton production, mainly in the Helmand Valley, to design, carry out and analyse experiments, to train technical assistants and give advice to Government officials and farmers

Qualifications A good degree in agriculture or related science, with experience of the experimental agronomy of tropical field crops, especially cotton

Salary £3,000–4,000 a year, according to experience subject to British income tax, plus a variable tax-free foreign service allowance ranging at present from £345–£880 a year, depending on marital status Contract 2 years

BOLIVIA

Animal Husbandry Expert (British Tropical Agricultural Mission) RC 213/22/05

Duties To advise and work in collaboration with Bolivian technicians on all aspects of the improvement of ranch management

Qualifications A degree in agriculture, preferably with a post graduate qualification or specialisation in the animal husbandry field, and ten years' experience in cattle ranch management

Salary £2,500–£3,100 a year, depending on qualifications and experience, subject to British income tax, plus a variable non-taxable overseas allowance currently payable at rates from £540–£1,310 a year depending on marital status Contract 2 tours of 18 months

BOTSWANA

Insecticide Formulations Expert RC 213/19/07

Duties To work on toxicity of insecticides on various pests on formulation deposits and residues, to undertake work for the protection of stored grain and to train a local officer

Qualifications and Terms An Honours Degree in either Zoology or Chemistry A practical knowledge of both subjects and an interest in the practical application of pesticides for crop protection is desirable

Basic salary Rands 4,200 (£ sterling 2,450) plus an inducement allowance at present £ Sterling 312 Terminal gratuity 25% of basic salary and inducement allowance Contract 2–3 years

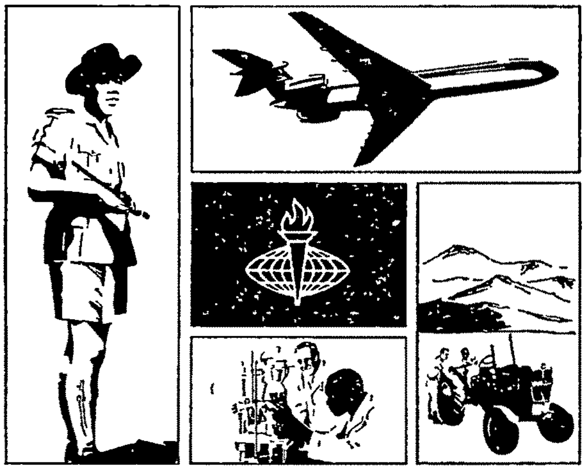
ETHIOPIA

Lecturers RC 213/58/04

Lecturers in Agricultural Science, Agricultural Mechanics, Agronomy or Farm Management are required to teach at the Jimma and Ambo Agricultural Schools

Qualifications and Terms A university degree with practical and teaching experience

Salaries £1,760–£2,700 a year, subject to British income tax, plus a variable non taxable overseas allowance ranging from £750–£1,580 a year, depending on marital status Contracts 3 years



MALAWI

Agricultural Research Officer RC 213/134/016

Duties To draw up and execute a programme investigating all aspects of rice agronomy under rain fed and irrigated conditions

Qualifications and Terms A degree in Agriculture and 5 years' experience in rice agronomy under tropical conditions

Salary £1,485–£2,600 a year, in addition a supplement of £100 a year is payable direct to the Officer's bank account outside Malawi and Rhodesia Tax free terminal gratuity of 15% to 25% Contract 24–36 months

MALAYSIA

Oil Palm Development Adviser RC 213/106/01

Duties To formulate an oil palm planting programme for the Federal Land Development Authority

Qualifications and Terms At least 15 years' practical and commercial experience in oil palm production A degree in agriculture is desirable

Salary £2,900–£3,000 a year subject to British income tax, plus a variable non-taxable overseas allowance ranging from £425–£1,275 a year depending on marital status Contract 2 years

SABAH

Agricultural Research Officers (Plant Breeders) RC 213/150/03

Duties To deal with the selection and breeding of oil palm and cocoa throughout the State of Sabah

Qualification and Terms An Honours degree in Natural Science with 2 years' post graduate training A good general knowledge of the subject is essential Field experience desirable

Salary $9,000–$17,040 a year (£ Sterling 1,226–2,321 a year) plus an inducement allowance at present in the range of £ Sterling 739–1,206 a year Terminal gratuity approximately 20% of basic salary and inducement allowance Contract 24–36 months

TRISTAN DA CUNHA

Agricultural Officer RC 213/179/01

Duties To stimulate agriculture and encourage young farmers

Qualifications A degree or diploma in agriculture with a good farming background and preferably some experience in dealing with small island communities

Salary £1,420–£1,966 a year 12½% gratuity Contract 2 years

UGANDA

Principal/Senior Research Officer RC 213/183/05

Duties To take charge of a small section of scientists investigating the breeding and selection of food crops

Qualifications and Terms At least a second class honours degree in Botany or Agricultural Botany with post-graduate training in plant breeding, and overseas experience

Basic Salary £ Ugandan 1,839–2,175 a year (£ Sterling 2,145–2,537) liable to Uganda income tax In addition an allowance normally tax free at present in the range of £ Sterling 888–936 a year will be paid by the British Government on behalf of the Uganda Government, direct to an Officer's bank account in Uganda 25% gratuity Contract 21–27 months

For further particulars of these vacancies and an application form please write giving your full name, age and brief details of professional qualifications and experience, and quoting appropriate reference number, to the Appointments Officer, Room 324/N/14 Ministry of Overseas Development, Eland House, Stag Place, London, S W 1.

MINISTRY OF OVERSEAS DEVELOPMENT

(922)

THE MEDICAL RESEARCH COUNCIL

invite applications for a newly established

SENIOR POST

in a group working on the

aetiology of tumours with special reference to man.

Applicants may be either scientifically or medically qualified and research experience in immunology, virology or genetics would be an advantage The unit has good access to clinical material and also has facilities for experimental work in virology, cell biology and biochemistry In addition to working in collaboration with other members of the group the successful candidate will be expected to develop original lines of research in this field

The salary will be in the range £1,905 to £2,630 per annum, depending on qualifications and experience

Applications giving a full curriculum vitae should be sent to the Administrative Officer, Medical Research Council, Clinical and Population Cytogenetics Research Unit, Western General Hospital, Edinburgh 4

(862)

MEDISCHE FACULTEIT ROTTERDAM

The Laboratory of Pathology of the Medical Faculty Rotterdam has available the following vacancies for senior staff-members

1. **Chief morbid anatomy service**
2. **Chief surgical pathology service and senior consultants in charge of**
3. **Cardiopathology**
4. **Pathology of the lung**
5. **Tumour pathology**

Qualified pathologists seriously interested in taking the responsibility for one of these functions are invited to send full information concerning their training and qualifications including a list of publications to Prof Dr H E Schornagel and Prof Dr M J de Vries, Academisch Ziekenhuis Dijkzigt, Dr Molewaterplein 40, Rotterdam, the Netherlands

(867)

UNIVERSITY STAFF

CALGARY, ALBERTA

The Geology Department expects to make appointments of one of the following specialists

GEOPHYSICIST Person expected to develop research and courses with emphasis on exploration for metallic mineral deposits

ENGINEERING GEOLOGIST Person expected to develop research and courses in engineering geology Experience in ground water hydrology and surficial geology an asset

Level of appointment for above positions would be commensurate with ability and experience Applicants with Ph D degrees will receive preference Presently the Department has 11 staff members and modern facilities Calgary is 40 miles east of the Rocky Mountains, has a population of 360 000 and is the centre of the oil industry in Canada

Submit applications, with résume and names of three referees to Dr P S Simony, Geology Department, The University of Calgary, Calgary, Alberta, Canada (603)

CANADA

THE UNIVERSITY OF MANITOBA

Invites applications from

LOW ENERGY NUCLEAR PHYSICS THEORISTS

DUTIES Teaching and Research

SALARIES Probably $12,000 to $18,000 per annum depending on qualifications All fringe benefits apply

FOR FURTHER INFORMATION WRITE

Dr A H Morrish,
Head
Department of Physics,
University of Manitoba
Winnipeg 19 Manitoba (498)

UNIVERSITY OF BRISTOL

DEPARTMENT OF ANATOMY

Applications are invited for a LECTURESHIP (Grade II) in the above Department, available from April 1, 1968 The duties of the post will be mainly concerned with the teaching of general and dental anatomy to dental students A good dental, medical or science degree is essential, teaching experience and ability in independent research would be an advantage Good facilities for research are available in the Department

Initial salary within the range £1,470 to £2,630 per annum, according to qualifications and experience

Applications (eight copies), together with the names of not more than two referees, should reach the Registrar, Senate House, Bristol, 2, from whom further particulars may be obtained not later than Monday, March 18 (Quote reference AL1) (919)

WOLVERHAMPTON HOSPITAL MANAGEMENT COMMITTEE

BIOCHEMIST

Applications are invited for the post of Biochemist (Basic Grade) Candidates should possess an Honours Degree in Chemistry or Biochemistry or equivalent qualifications in Chemistry In addition to routine work opportunities exist for instructon in background pathology and for research Candidates may visit the Laboratory by arrangement with Dr G Walters at New Cross Hospital, Wolverhampton

Applications, with names of two referees to the Group Secretary, Royal Hospital, Wolverhampton (918)

UNIVERSITY COLLEGE OF NORTH WALES

BANGOR

MARINE SCIENCE LABORATORIES

DEPARTMENT OF MARINE BIOLOGY

Applications are invited for three teaching posts in zooplankton, phytoplankton and marine microbiology The posts will be offered on one of the following scales

Demonstrator (two posts) £865 per annum

Assistant Lecturer £1,105 by £75 to £1,180 by £80 to £1,340

Lecturer £1,470 by £90 to £2,010 by £85 to £2,180 by £90 to £2 630

In addition there will be F S S U benefits

Applicants for the Demonstratorships should have a good Honours degree in an appropriate subject The successful candidates may register for a higher degree of the University of Wales

Applicants for the post of Lecturer or Assistant Lecturer must have relevant research experience

Two copies of the application, with the names of three referees, should be sent, not later than March 11, 1968, to the Registrar, University College of North Wales, Bangor, from whom further particulars may be obtained (843)

UNIVERSITY OF LAGOS

NIGERIA

FACULTY OF ENGINEERING

Applications are invited for the following posts tenable from September, 1968, or soonest thereafter

(a) Civil Engineering (I) Chair (II) Senior Lectureships or Lectureships in the following fields (i) Hydraulics and Hydrology and (ii) Transportation

(b) Electrical Engineering (I) Chair (II) Senior Lectureships or Lectureships in the following fields (i) Control, (ii) Power, and (iii) Telecommunications

(c) Mechanical Engineering (I) Chair (II) Senior Lectureships or Lectureships in the following fields (i) Thermodynamics and (ii) Fluid Mechanics

Salary scales Professor £N3,000 per annum Senior Lecturer, £N2,275 to £N2,575 per annum Lecturer, £N1,200 to £N2,175 per annum (£N1 equals £1 3s 4d sterling) Salary supperannuation in range £240 to £600 per annum (sterling) in appropriate cases under British Expatriates Supplementation Scheme Family passages; various allowances, superannuation scheme

Detailed applications (6 copies) naming three referees, by April 22 1968 to Inter-University Council, 33 Bedford Place London W C 1, from whom particulars are available (886)

UNIVERSITY OF THE WEST INDIES

TRINIDAD

Applications invited for (a) Senior Lectureship or (b) Lectureship in Agricultural Economics in Department of Agricultural Economics and Farm Management Competence in production economics advantageous but extreme specialisation is not sought Salary (a) £2 250 to £3,405 per annum, (b) £1,550 to £2 630 per annum Child allowance F S S U Family passages

Detailed applications (6 copies) naming three referees by April 1, 1968 by persons living in the Americas and the Caribbean area, to Secretary, University of the West Indies, St Augustine Trinidad, and by all others to Inter-University Council, 33 Bedford Place, London W C 1 Further particulars may be obtained similarly (887)

UNIVERSITY OF ST. ANDREWS

LECTURESHIP OR ASSISTANT LECTURESHIP IN PHYSICS

Applications are invited for the post of LECTURER OR ASSISTANT LECTURER IN EXPERIMENTAL PHYSICS Candidates should have special qualifications or interests in one of the following fields Low Temperature, including solid state, Laser Physics, X-ray Crystallography Further information from Professor J F Allen, Department of Physics Salary scales Lecturers £1 470 to £2,630, Assistant Lecturers, £1 105 to £1,340, starting salary in each case according to qualifications and experience F S S U, grants towards expenses of furniture removal

Five copies of applications, with the names of three referees, should be lodged with the Secretary of the University, College Gate, St Andrews, by March 23, 1968 (856)

BEECHAM RESEARCH LABORATORIES

have a vacancy for a

TECHNICIAN FOR THE TOXICOLOGY UNIT

The successful applicant will be required to work primarily on serum biochemical determination, including enzyme techniques, in a variety of animal species He or she should have had some experience of routine hospital or other pathology laboratory techniques and should have reached the intermediate I M L T. standard Experience of automated or work simplification methods would be an advantage, but is not essential

Applications are invited from young men or women, who would be given the facilities of day release if required These laboratories are recognized by the I M L T for the purpose of study for further qualifications

An attractive starting salary is offered and reviewed regularly, along with generous fringe benefits including sick pay, profit sharing, and non-contributory pension with life assurance schemes

Please write, stating briefly age, qualifications and experience, to **The Personnel Officer, Beecham Research Laboratories, Brockham Park, Betchworth, Surrey.**

(841)

UNIVERSITY OF EXETER

CHAIRS IN BIOLOGICAL SCIENCES

Applications are invited from suitably qualified persons for two Chairs from October, 1969, when, following the retirement of Professor Caldwell and Professor Harvey, the existing Departments of Botany and Zoology will be merged into a Department of Biological Sciences The Professors-Designate will in 1968/69 be expected to act in a consultative capacity in relation to planning courses and accommodation

The salary will be not less than £3,570 per annum

Further particulars may be obtained from the Secretary of the University, Northcote House, The Queen's Drive, Exeter to whom applications should be submitted (fourteen copies one copy from candidates overseas) by April 1, 1968 (846)

UNIVERSITY OF NOTTINGHAM

Applications are invited from Honours graduates in Zoology, Entomology or Agricultural Zoology (including 1968 graduands) for DEMONSTRATORSHIP IN AGRICULTURAL ZOOLOGY in the Department of Physiology and Environmental Studies, School of Agriculture Sutton Bonington Candidates should preferably be interested in Soil Zoology, Acarology or Nematology Salary scale £800 by £25 to £850 per annum

Conditions of appointment and forms of application, to be returned by March 4, 1968, from the Registrar, University of Nottingham University Park, Nottingham, NG7 2RD (842)

Organic Chemists

Vacancies exist in our Process Development Department for Organic Chemists (preferably 24 to 27 years of age) with Ph D degrees or equivalent research experience, and a lively interest in synthetic organic chemistry

The work is largely concerned with the development of processes for new medicinal products, and covers a wide field of organic chemistry The Department is closely associated with both Research Department and the Plant, and is housed in modern, well equipped laboratories in pleasant surroundings

The attractive conditions of service would be discussed at interview The successful candidates, if married, may receive a reasonable refund of removal and travel expenses and, if necessary, assistance in house purchase

Applications giving brief details of age, qualifications and experience should be addressed to

G W Peters,
Senior Personnel Officer,
IMPERIAL CHEMICAL INDUSTRIES LIMITED,
PHARMACEUTICALS DIVISION,
Alderley House, Alderley Park,
Macclesfield, Cheshire

(861)

A large industrial Company in the North of England has a vacancy for an experienced

APPLIED MATHEMATICIAN

of high ability to work on selected projects of great mathematical interest. It is expected that the first project will be the construction of a highly sophisticated mathematical model of a tidal river. The successful applicant would find himself a member of a substantial mathematical group inside a keen technical management team, and would have easy access to first class computer facilities. The starting salary would be negotiable , a salary above £2,500 p a could be offered to a highly qualified and experienced applicant Please apply to Box No 951, *Nature,* T G Scott & Son Ltd , 1 Clements Inn, Strand, W.C 2

(854)

ELECTRON MICROSCOPIST

for Industrial Research

Gillette Research Laboratories have a vacancy for an electron microscopist to work on hair structure and polymers

The work entails the use of ultra-thin sectioning techniques, as well as general electron microscopy Experience in one or both of these fields will be required, and candidates should be qualified to HNC, BSc, or equivalent standard

Please write with details in confidence to,

Dr. N C. Welsh (Ref N.4401), Head of Laboratory,
Gillette Research Laboratory,
454 Basingstoke Road, Reading, Berks.

(938)

UNIVERSITY OF MANCHESTER
MANCHESTER, 13

LECTURERS AND ASSISTANT LECTURERS IN CHEMISTRY

Applications invited for a number of posts vacant now or from October 1968 It is hoped to make at least one appointment in each of the fields inorganic, organic theoretical No field of interest excluded from consideration Salary ranges per annum Assistant Lecturer, £1 105 to £1 340 , Lecturer, £1,470 to £2,630 F S S U

Particulars and application forms (returnable by March 22) from the Registrar Quote ref 20/68/Na (914)

NEW ZEALAND

DEPARTMENT OF SCIENTIFIC AND INDUSTRIAL RESEARCH

Applications are invited for the undermentioned vacancy

SCIENTIST

Vacancy B 13/18/66/533

Plant Chemistry Division, Department of Scientific and Industrial Research, Palmerston North, New Zealand

Salary Up to $6,830 per annum is available according to qualifications and experience

The position would suit either an established Scientist or a recent graduate with training in microbiology with interests in one of the following fields—ruminant digestion, microbial ecology or ruminants, pregastric fermentation, biochemistry of pure species of rumen bacteria and protozoa or rhizobium research These are established lines of work within the Division in which an intensified effort is required

Passages Fares for appointee and his wife and family, if married, will be paid

Incidental expenses Up to £35 for a single man and £100 for a married man can be claimed to cover the cost of taking personal effects to New Zealand

Application forms and general information are available from the High Commissioner for New Zealand, New Zealand House, Haymarket, London, S W 1 with whom applications will close on March 27, 1968

Please quote reference B 13/18/66/533 when inquiring (915)

UNIVERSITY OF BRISTOL

DEPARTMENT OF ANATOMY

It is hoped to appoint two LECTURERS (Grade II) in the above Department after May 1, 1968 A good medical, dental or science degree is essential together with teaching experience and ability in independent research (e g , neurobiology cytogenetics, electron microscopy, histochemistry)

Initial salary within the range £1 470 to £2,630 per annum, according to qualifications and experience

Applications (eight copies), together with the names of not more than two referees, should reach the Registrar, Senate House, Bristol 2, from whom further particulars may be obtained, not later than Monday, March 18, 1968 (Quote reference AL23)

(920)

SIMON FRASER UNIVERSITY

(Located in the Vancouver area of British Columbia, Canada)

Department of Chemistry currently 24 faculty members has senior-level vacancy for a BIOCHEMIST or PHYSICAL ORGANIC CHEMIST

Enquiries to Brian D Pate, Head, Department of Chemistry Simon Fraser University, Burnaby 2, B C , Canada

(875)

UNIVERSITY OF SURREY

DEPARTMENT OF BIOCHEMISTRY

SENIOR LECTURER

Applications are invited for the post of Senior Lecturer in the Department of Biochemistry Candidates should have a wide experience in the teaching of biochemistry and have a research interest in pharmacological biochemistry and/or biochemical methodology

The commencing salary will be at an appropriate point on the Senior Lecturer Scale £2 520 to £3 150 (bar) to £3 415 per annum with a deduction of 5 per cent for superannuation (F S S U)

Applications together with the names and addresses of not more than 3 referees should be received not later than March 15 1968 by the Academic Registrar (LFG), University of Surrey Battersea Park Road London S W 11 from whom further particulars may be obtained (901)

UNIVERSITY OF OXFORD

LECTURESHIPS IN EXPERIMENTAL PHYSICS

Applications are invited for University Lectureships in Experimental Physics (pure or applied) in the Clarendon Laboratory and in the Department of Nuclear Physics which may be held in conjunction with Fellowships at Magdalen College or St Edmund Hall or (for a woman) at St Anne's College

Applications (four copies) with a statement of career and qualifications and the names of three referees must be received by April 15 1968 For the University Lectureships further details are available from the Secretary of Faculties University Registry Broad Street Oxford , for the College Fellowships from the President Magdalen College , The Principal St Edmund Hall , The Principal, St Anne's College, Oxford (881)

MAGDALEN COLLEGE OXFORD

OFFICIAL FELLOWSHIP IN PHYSICS

The Governing Body proposes to appoint an OFFICIAL FELLOW IN EXPERIMENTAL PHYSICS from October 1 1968 The post may be held in conjunction with one of the University Lectureships currently advertised by the Clarendon Laboratory and the Department of Nuclear Physics from the same date

Applications, with a brief statement of academic record research interests and names of three referees should be sent, not later than April 15, 1968, to the President Magdalen College Oxford from whom further details may be obtained (880)

COMMONWEALTH AGRICULTURAL BUREAUX

Vacancy for

SCIENTIFIC INFORMATION OFFICER

Commonwealth Bureau of Soils,
Harpenden Herts

Duties include preparing abstracts for the abstracting journal SOILS AND FERTILIZERS, which covers the world scientific literature on soils and soil/plant relationships dealing with scientific inquiries within these fields Essential qualifications a degree in agricultural science or in sciences basic to it ability to write good English Reading knowledge of foreign languages and experience or training in information work would be advantages Salary in scale £926 to £2 431 with provision for superannuation Starting salary according to qualifications experience and age Two extra increments after two years' satisfactory service for applicant aged 32 or under on date of appointment

Application forms and full particulars from Director Commonwealth Bureau of Soils Rothamsted Experimental Station, Harpenden, Herts (878)

POSTGRADUATE STUDIES IN PHYSICS

UNIVERSITY OF VICTORIA

VICTORIA BRITISH COLUMBIA CANADA

The Department of Physics offers assistantships for students working towards M Sc and Ph D degrees in Physics Fields of research include theoretical physics astrophysics physics of fluid geophysics and nuclear physics Financial assistance is available in the range from $2 300 to $4 600 per annum

Details of this assistance and of the fields of research may be obtained from Professor J L Climenhaga, Head, Department of Physics University of Victoria, Victoria, British Columbia, Canada (873)

Scientific Officer, Senior Scientific Officer

Metallurgy Division • A.E.R.E. Harwell

Many challenging scientific problems remain to be solved in the development of advanced reactor systems In particular, a better understanding is needed of irradiation effects in high temperature alloys and ceramic fuels Also there is need to apply the latest ideas to develop materials with improved mechanical properties and corrosion resistance for use in nuclear technology A vigorous research programme on these topics is in progress in the Metallurgy Division at Harwell and we have a vacancy for a scientist, with energy and imagination, in each of the two research teams engaged on these studies The work is closely linked both to more applied studies in the Authority's Reactor Group and to more fundamental studies at Harwell and in the universities

The facilities at Harwell for carrying out this work are among the best in the world and include three research reactors, post-irradiation examination cells, particle accelerators, computers, electron microscopes, (a 1 MeV microscope will be installed in 1969), electron microprobes, a scanning electron microscope, low-energy electron diffraction sets, field ion microscopes, and a wide range of mechanical testing equipment

Candidates should have a first or good second class honours degree, preferably in physics, metallurgy or engineering Previous experience in these fields is not essential but some experience of the mechanical and physical properties of solids is desirable There is ample opportunity to keep abreast with modern developments by attending Colloquia and courses run by the Harwell Post-Graduate Education Centre.

Starting salary will be at a point on the scales £995 to £1,685 or £1,870 to £2,310 depending upon age and experience Married officers living beyond daily travelling distance will be eligible for Authority Housing or Assisted House Purchase

Application forms and further details may be obtained from

Appointments Section 'A', A 523034
A E R.E , Harwell, DIDCOT, Berks.

(839)

SIMON FRASER UNIVERSITY

Research Opportunities in Chemistry

The Department of Chemistry of this rapidly growing university, which is situated on the outskirts of the City of Vancouver, has openings for suitably qualified students in the graduate programme leading to the degrees of M Sc and Ph D Qualified honours degree in Chemistry, or A R I C Financial assistance in the form of teaching assistantships and research assistantships, to the value of $3,100 per annum in the first year, will be available to suitable candidates The trimester system in operation at Simon Fraser University allows students to enter the graduate programme in September or January

Interested persons should write in the first place to

The Chairman, Graduate Admissions Committee,
Department of Chemistry,
Simon Fraser University,
Burnaby 2, B.C. CANADA

(874)

SCIENTIFIC INFORMATION OFFICER

(Female)

The Industrial Hygiene Research Laboratories of Imperial Chemical Industries Limited, situated at Alderley Park in Cheshire, are responsible for determining the toxicological hazards of the chemicals used by the manufacturing divisions of the Company As part of this service there is an Information Bureau staffed by female graduates who index items of toxicological interest in the literature and answer enquiries on toxicological subjects

Applications are invited for a vacancy in this department Candidates should be up to 30 years of age and graduates in chemistry (with a biological subsidiary subject), biochemistry, pharmacy or zoology (with chemistry as the subsidiary) Previous experience in information work is not essential

Progressive salary plan profit sharing scheme pleasant rural surroundings

Applications and enquiries should be addressed to **O. B. Sayer, Assistant Staff Manager, I C.I. Limited, Fulshaw Hall, Wilmslow, Cheshire.**

(840)

ANIMAL HEALTH TRUST

Applications are invited from registered members of the veterinary profession for the post of DIRECTOR of the Trust's Small Animals Centre at Lanwades Park Kennett, near Newmarket, Suffolk The applicant should have had research experience relating to the improvement of health and the control of disease in dogs cats and other small animals He should be capable of directing the work of a small but busy centre dealing with these species

Salary according to qualifications, commencing in the range of £3 600 to £4 100 per annum Superannuation under F S S U

Further particulars and form of application may be obtained from the Secretary, Animal Health Trust, 14 Ashley Place, London, S W 1 (799)

UNIVERSITY OF EXETER

ASSISTANT LECTURER IN PSYCHOLOGY

Applications are invited for a post of Assistant Lecturer in Psychology tenable from October 1, 1968

Postgraduate training or research in experimental or clinical psychology is required

Salary scale £1,105 by £75 to £1,180 by £80 to £1,340 per annum Initial salary will depend upon qualifications and experience

Further particulars may be obtained from the Secretary of the University, Northcote House, The Queen's Drive Exeter Closing date for applications (eight copies one copy from overseas candidates) April 16, 1968 (898)

UNIVERSITY OF EDINBURGH

Chair of Geophysics

Applications are invited for the Chair of Geophysics, tenable from October 1, 1968, or from a date to be arranged The Professor will be Head of a newly established department Salary within the professorial range with membership of F S S U

Further particulars may be obtained from The Secretary to the University, Old College, South Bridge, Edinburgh, with whom applications (twelve copies), giving the names of three referees, should be lodged not later than April 1, 1968 Overseas candidates need submit only one copy of their application (853)

UNIVERSITY COLLEGE OF WALES

ABERYSTWYTH

DEPARTMENT OF AGRICULTURAL BOTANY

Applications are invited for the post of ASSISTANT LECTURER in the above Department with a special interest in Genetics and Biological Statistics Postgraduate experience desirable

Application forms are obtainable from the Registrar, to whom all applications should be sent by April 1, 1968 (746)

UNIVERSITY OF EAST AFRICA

MAKERERE UNIVERSITY COLLEGE, UGANDA

Applications are invited for a Readership in the Department of Zoology Appointment may be on permanent terms (East African citizens only) or on contract terms Appointee must have interests in fresh water ecology hydrobiology and/or ichthyology Salary scale £EA2 540 to £EA2 825 per annum (one E A shilling equals 1s 2d sterling) Salary supplemented in range £495 to £485 (sic) per annum (sterling) in appropriate cases under British Expatriate Supplementation Scheme Part-furnished quarters at rent not exceeding £EA114 per annum Expatriate appointees receive up to five adult economy class air passages on appointment and leave, up to five adult sea passages on termination additional children's air passages for children educated overseas, leave of 3 months after 21 months

Detailed applications (6 copies) naming three referees, by April 11, 1968 to Inter-University Council 33 Bedford Place, London W C 1, from whom particulars may be obtained (888)

UNIVERSITY OF EAST AFRICA

MAKERERE UNIVERSITY COLLEGE— UGANDA

Applications are invited for (a) Lectureship or (b) Assistant Lectureship in Geography available from July, 1968 Specialists in any fields considered existing knowledge of East Africa advantageous Salary (a) £EA1,350 to £EA2,230 per annum, (b) £EA1,125 to £EA1 245 per annum (one EA shilling=1s 2d sterling) Salary supplemented in appropriate cases under British Expatriates Supplementation Scheme in range £265 to £410 per annum (sterling) F S S U Family passages, biennial overseas leave

Detailed applications (six copies), naming three referees by April 5 1968, to Inter-University Council, 33 Bedford Place, London, W C 1, from whom particulars are obtainable (925)

UNIVERSITY OF EAST AFRICA

UNIVERSITY COLLEGE, NAIROBI

Applications are invited for the Chair of Physics Salary £EA3,150 per annum (one EA Shilling=1s 2d Sterling) Salary supplemented in appropriate cases by £505 per annum (Sterling) under British Expatriates Supplementation Scheme Expatriates are usually appointed on two-year tours F S S U Subsidised accommodation Passages for appointee and family (up to five adult passages) on appointment and termination

Detailed applications (six copies), naming three referees by March 31, 1968, to Inter-University Council, 33 Bedford Place, London, W C 1 from whom particulars are available (909)

UNIVERSITY OF THE WEST INDIES

TRINIDAD

Applications are invited for (a) **Lectureship** or (b) **Assistant Lectureship** in Agriculture, Department of Crop Science Applicants should possess a degree in agriculture (or its equivalent) and preferably some experience in teaching and research Tropical experience very desirable but not essential Salary scales (a) £1 550 to £2,630 per annum (b) £1,250 to £1,410 per annum Child allowance F S S U Family passages Triennial study leave

Detailed applications (6 copies), naming 3 referees by April 5, 1968, by persons living in the Americas and Caribbean area to Secretary, University of the West Indies, St Augustine Trinidad, and by all others to Inter-University Council, 33 Bedford Place, London, W C 1 Further particulars obtainable similarly (924)

CAMBRIDGE UNIVERSITY SCHOOL OF Agriculture Applications invited for posts of University Demonstrator and Farm Demonstrator Qualifications an honours degree in Agriculture or Agricultural Science or an honours degree in pure science followed by an adequate postgraduate qualification in Agriculture For University Demonstrator, candidates should also have had postgraduate experience in research and/or teaching For Farm Demonstrator, preference will be given to candidates with previous training in field experimentation Salary scales University Demonstrator, £1,260 by £80 to £1,420 by £50 to £1 470 by £90 to £1,650, Farm Demonstrator, £1,050, £1 105, £1,180 by £80 to £1,420 Starting point according to age qualifications and experience Both posts pensionable under F S S U Contribution may be made towards removal expenses Further details on request —Apply in writing giving full personal particulars and names and addresses of not more than three referees, to the Secretary, School of Agriculture, Cambridge, not later than March 28, 1968 (905)

NATURE Volume 217
MARCH 9, 1968

Can Europe Stay the Same?

The third meeting of science ministers which the OECD is promoting in Paris next week will return to a theme which has not been very far beneath the surface in the past decade—the supposed technology gap between Europe and the United States. This is perhaps inevitable, if only because the ministers who will be meeting in Paris are almost all of them conscious of the need somehow to justify their expenditure in economic terms, which is often taken to imply that the object of European policies in science and technology should be somehow to make Europe as prosperous as the United States. On this occasion, it is also possible that discussion of the technology gap will provide a convenient means by which the Minister of Technology, Mr Wedgwood Benn, can explain just what is to be understood by the recently canvassed concept of a European Institute of Technology. This institute, still nebulous, seems to be most of what is left of the brave talk a year ago of how the United Kingdom would with the mainland of Europe forge what was fondly called a European Technological Community. Other governments than the British will no doubt be fascinated to know whether the institute which the Ministry of Technology has in mind will be a kind of academic body or whether, as has sometimes been suggested, the institute would emerge as Mintech writ large, and presumably diffuse. At the same time, it will not necessarily be a pointless exercise if they are induced by circumstances to consider yet again the contrast between the two sides of the Atlantic, for there is no question that Europe has much to learn.

But what? The greatest danger is that, in making the necessarily somewhat hackneyed comparisons with the United States which have almost become second nature, Europeans may be tempted to consider, as harbingers of industrial change and economic prosperity, attributes of the industrialized American society which are, in reality, no more than consequences. For one thing, it is not a trivial question to ask which comes first, the technology gap or the prosperity gap. There may even be something in the view that research and development are not only preconditions for prosperity but also luxuries which only the well-to-do can properly afford. Certainly it is no accident that both Japan and Italy, when bent on really rapid economic progress, chose to rely much more heavily on licences to exploit other people's inventions than on research and development of their own. And which but the most prosperous nation in the world would have been able to afford the exploits of the National Aeronautics and Space Administration this past decade? The trouble is that this plain truth and others like it have not been nearly as widely appreciated as they should have been. In Britain and elsewhere, there has been quite a clamour in favour, for example, of emulating the United States in unrestrained expenditure on space research and development in the fond belief that this will somehow create prosperity. To be sure, this is a trap which almost everybody should be able to avoid, but many other traps are much more carefully concealed.

The chances are that Europe has in any case already done a great deal to learn one of the most important lessons to be learned—the need to make Europe commercially competitive with the United States. In part, this objective raises problems of scale. On the mainland there is the EEC, which will in time become a powerful device for increasing industrial production and thus, in the end, for supporting a buoyant and stimulating effort in research and development. Positive feedback is what the electrical engineers would call it. In Britain, mergers between previously competing companies have become the order of the day, legislation on monopolies notwithstanding, in part at least because people seem to recognize that it has become difficult for small companies to be at once progressive and comprehensive. To the extent that the Ministry of Technology has deliberately created the climate in which mergers have become fashionable, Mr Wedgwood Benn will be able to preen himself a little in Paris. But everyone will recognize that problems of scale are not the only ones to be resolved before the technology gap will disappear. Management—its quality and skill—should come high on the list of lessons appreciated but not yet learned. Financial institutions will also have to change, and this is likely to be painfully slow. So, too, will governments and, in the long run, it is more than probable that Europe will not be able to close what seems to be the technology gap until the whole fabric of society has been in some way touched. Science and technology have an important part to play, and without them nothing would be possible, but it is folly to expect that they can be the mainsprings of the changes which the ministers wish to see.

The general truth of this proposition is splendidly illustrated by the perceptive study of the relationship between *Fundamental Research and the Universities*

INSTRUMENTATION

This is the time of the year when British universities make plans for spending money on equipment. The Labex exhibition was held in Manchester last month and next week there will be the annual exhibition of the Institute of Physics and the Physical Society at Alexandra Palace. To mark these events, this issue of *Nature* includes two articles on recent developments in laboratory technique (page 913).

which has been prepared by Professor Ben-David of the University of Jerusalem as one of the documents for the meeting of ministers. To summarize his persuasive argument is almost unjust, but it goes something like this. The disparity between the United States and Europe which Europeans are willing enough to acknowledge where the application of science is concerned is also now apparent in basic and fundamental science, however those terms are defined. Professor Ben-David splits a few hairs in adding up Nobel Prizes and published papers in the learned journals, but the essence of his case is qualitative and not arithmetical. American science is vigorous and creative because of the way in which it is organized, with plenty of opportunities for teams of people to compete against each other and to seek out new problems to solve. Not merely are there competing sources of funds for the support of research, but a variety of institutions in which people can pursue their scientific ends. Professor Ben-David calls this entrepreneurship, and in his view Europe falls behind the United States because it lacks the kind of institutional framework within which this kind of activity can be carried forward.

The most distinctive part of Professor Ben-David's argument consists of a plea for the removal of the hierarchical structure of European universities. In his view, Britain is a kind of half-way house between the rest of Europe and the United States, and what he calls the Cambridge–Oxford–London triangle is in every way comparable with the Cambridge complex in Massachusetts. The concentration around Paris of universities and other institutions for research is a similar hotbed of innovation, particularly because of the way the Collège de France provides an analogue for the reputable institutes for advanced study which have sprung up in the United States. But exceptions to the general rule that European science is organized too rigidly, and that it is as a consequence too constrained and even too inhibited, are at once fewer and less effective than they might be.

In the past few months in Europe, this has become a familiar cry. With luck, it may become a clamour in the years ahead, and there is every chance that Professor Ben-David's tract will have an important influence. His statement of the need for a structural upheaval of the administration of academic institutions is persuasive and subversive (which is, no doubt, why the OECD's introduction emphasizes that Professor Ben-David's views are not official policy). The truth is, of course, that even in Britain, which is only comparatively enlightened in these things, there is a tendency to assume that existing institutions must continue to exist substantially unchanged.

In this climate, for example, new kinds of university departments can be created only with the funds which are not required for established disciplinary structures. It is hard to shut down laboratories which already exist but which have outlived their immediate usefulness, but extremely difficult to embark on laboratories which the European Molecular Biology Organization would like to establish. Brooding over all of this is a sophisticated system of committees which has become increasingly devoted to the belief that it is possible to make supposedly judicial decisions about the spending of money in circumstances when it may well be that the only meaningful decisions are those which enable vigorous people to keep on being vigorous. And if this complaint is valid in Britain, Professor Ben-David is right in saying that Britain and France are luckier than most other European nations. He is also right to imply that it would be possible for Europe as a whole to attend to these structural problems without compromising its attitude towards other aspects of the comparison between Europe and the United States. The point is that a more flexible, and a more European, framework for the administration of fundamental research in Europe is desirable in its own right. The fact that it would help to close whatever gap there may be across the Atlantic is an extra benefit.

Science Policy Meeting

On March 11 and 12, ministers of science and education from 22 different countries will be meeting in Paris at the headquarters of the Organization for Economic Co-operation and Development. Representing Britain will be Mr Patrick Gordon Walker and Mr Anthony Wedgwood Benn. Among other subjects scheduled for discussion is one of Europe's recurrent preoccupations, the technological gap between Europe and the United States. The ministers will be discussing a report produced by OECD which sets out to establish the factual basis for the technological gap. The report, which will not be published in full until after the Paris meeting, studies nine sectors of industry—computers, scientific instruments, pharmaceuticals, plastics, non-ferrous metals, man-made fibres, iron and steel and machine tools. The report assesses the performance of the various industries both as performers of research and development and as industrial innovators, and attempts to relate these to industrial prosperity.

The ministers will also be discussing fundamental research policy, and scientific and technical information systems and policies. The discussion on fundamental research will hinge on several reports published by OECD in recent years; the most recent is an independent survey carried out for the organization by Professor Joseph Ben-David, professor of sociology at the Hebrew University of Jerusalem. Professor Ben-David concludes that European universities are inefficient; this, he says, is because chairs are established on the assumption that one man is capable of representing, more or less on his own, an entire discipline for about the lifetime of a generation. This, Professor Ben-David says, is palpably out of date, and he suggests instead the formation of large multidisciplinary research institutes able to award at least research degrees. Professor Ben-David recognizes the danger that institutes of this kind, far from being centres of innovation, often become bulwarks of traditionalism, and he suggests that they should be experiments in the true sense of the word. "Whatever schemes are adopted or considered, the expected objects should be defined and the results tested and published" The discussion next week is intended to make these ideas more precise, and the OECD is certainly hoping that a pilot scheme for a project of this sort may be approved

The final discussion will be on the problems of information retrieval As well as the technical difficulties of retrieval, there are distinct dangers that the various types of retrieval system now being developed will be incompatible If the United States devises a retrieval system which Europe is unable to plug into, many of the advantages of the system will be lost

Not Enough Uranium

THE rapid expansion of nuclear power has meant that electrical utilities, particularly in the United States, have had to take a hard look at the supplies of uranium Like most mineral resources, the stocks seem to be limited Some argue that this will enforce a much greater reliance on coal fired stations—or, at the other extreme, on the successful development of fusion reactors More optimistic observers point out that this fear of shortage is a familiar part of mining operations, without which no mining company would ever feel like prospecting Between 1935 and 1965, for example, petroleum reserves ranged from ten to fourteen times annual requirements Despite or, some might argue, because of the potential shortage, exploration kept ahead of demand

The European Nuclear Energy Agency and the International Atomic Energy Agency have now got together to produce revised estimates of uranium resources Briefly, the conclusion is that not enough has yet been found Substantial new reserves are needed if estimated demand is to be met The report says that "there is no reason to suppose that such deposits will not be found if a massive, well-financed and well-conceived prospecting effort is undertaken However, the magnitude and urgency of the effort that will be required cannot be too strongly emphasized"

Uranium is widely distributed throughout the world, although Canada, the United States and South Africa have the lion's share The report estimates that the amount of uranium available at a sensible price—less than $10 per lb of U_3O_8—is about 7,000 short tons, with a further 126,000 short tons available as by-products of other industrial processes For a higher price, of course, much more is available In the range between $10 and $30 per lb, there are probably a further 1,400,000 short tons For comparison, the US Atomic Energy Commission estimated in 1966 that the probable world demand for U_3O_8 would be 65,000 short tons by 1980 Assured reserves at a fair price probably therefore represent ten to fifteen years supply, and the estimate means that annual production will have to be more than trebled by 1980

All this is going to make uranium mining a growth industry over the next ten years. On the face of it, there is no great cause for alarm—large areas of the world have yet to be thoroughly prospected, and little is known in the West about reserves in Communist countries The sea may also provide an alternative source of uranium, and the United Kingdom Atomic Energy Authority has estimated that the sea contains some 4,000 million tons of the mineral. This could be extracted at a price, although it seems to be too great a price to make the process immediately attractive Technological development will also help, and the most important element in this is likely to be fast breeder reactors, which will make much better use of uranium-238, converting it to plutonium and burning that as fuel While modern water reactors reflect a dollar increase in the price per lb of U_3O_8 by an increase in generation cost of 0 08 mill per kWh, fast breeders will be less sensitive to raw material costs.

Science School

THE Science Foundation for Physics within the University of Sydney is to hold its second International Science School for high school students from August 26 to September 6 this year The school, directed by Professor H Messel, who first conceived the idea, will be on the general theme, "Man in Inner and Outer Space" Twenty students from the United States, Japan and Britain will join one hundred and four students from Australia and New Zealand for the course of twenty lectures given by Australian and overseas scientists—seven of the lectures, for some reason, will be on America's projected manned Moon landing

Overseas scholarships were first offered last year to ten American students This year is the first time that the scholarships have been extended to Britain and Japan The ten American students will once again receive their awards personally from President Johnson Similarly, the Japanese Prime Minister, Mr Eisaku Sato, will sponsor the five Japanese representatives The British students, on the other hand, will have to be content with the Royal Institution, under the patronage of the Duke of Edinburgh The five British recipients of the scholarships will be known as the "Royal Institution Australian Science Scholars" The five lucky students were chosen from schools all over the country with the assistance of the Association for Science Education. All the winners will get a round-the-world air ticket with a two-week stay in Sydney for the Science School

More Chemists Needed

How is industry to attract its fair share of science graduates? The chemical industry is tackling this problem by organizing a conference with the theme "Modern Chemistry in Industry", to be held at Eastbourne between March 11 and 14 An attendance of about 1,000 is expected at the conference, including representatives from industry, government and the trade unions, but the majority will be science teachers and lecturers from the schools and universities.

The problem to be faced is two-fold—the flow of school leavers into the sciences needs to be increased, and more graduates must be encouraged to work in industry The organizers of the conference point to a lack of balance in the educational system. The drift away from science in the schools continues, leaving unfilled places in university science departments, while the arts faculties are having to turn away highly qualified candidates Even if the school leaver can be persuaded to enter a university science department, he is likely to fall prey to the notion widespread among graduates that research by industrial organizations is in some way inferior to that done in the universities

The conference will try to improve industry's scientific reputation among science teachers, in the hope that some of their enthusiasm will filter through to their pupils. To this end the conference will mainly consist of a series of lectures on various aspects of contemporary industrial chemistry, designed to illustrate the volume and quality of industrial research.

The Royal Society is sponsoring the meeting through the British National Committee for Chemistry. The majority of the speakers come from the chemical and allied industries, which are also paying for the conference. The speakers include Lord Beeching, a deputy chairman of ICI, Lord Sherfield, chairman of the Industrial and Commercial Finance Corporation, and Dr M. E. Spaght, a managing director of the Royal Dutch Shell Group. The president of the conference is Lord Todd, professor of organic chemistry at the University of Cambridge.

This is not the first conference to be held along these lines. The Science Research Council, in association with the Careers Research and Advisory Centre, staged an experimental summer school in Oxford last year to persuade postgraduate students carrying out research in university science departments to consider management as a career. The students and the managers from industry who attended must have benefited from the free exchange of ideas encouraged by a summer school.

It is difficult to see how a similar exchange of views, essential if managers are to become more aware of the academic scientist's impression of industry, will be possible within the formal framework of the Eastbourne meeting. The chemical industry is nevertheless probably correct in realizing the important part played by the schools in influencing choice of careers. If it can demonstrate to the teachers that industrial research is as challenging and as intellectually demanding as academic work, it may go some way towards helping its own recruitment of scientists.

Whence Foot and Mouth?

Lamb from Argentina was the probable source of the British foot-and-mouth epidemic that first broke out on a Shropshire farm last October and has since led to the slaughter of some 443,000 animals. This conclusion—hotly disputed by the Argentinian Embassy in London—is made in the report compiled by the Ministry of Agriculture and published this week.

The report bases its case on the circumstantial evidence that Argentine lamb was supplied to the farm where the epidemic first began, and on the failure to discover any other possible source of infection. In an admirably thorough piece of detection, Mr John Reid, the Ministry's chief veterinary officer, has established that the disease could not have been introduced to the Shropshire farm by the movement of humans or animals, and he considers that, although there were 3,000 cases of the disease last year in Western Germany, it could not have been transmitted either by the winds or by birds. "The distance is too great for the disease to have been brought from Germany to Shropshire by birds", he says, and presumably—though this is not stated in the report—the route does not correspond to any migratory pattern.

Ruling out imported hay and a previous outbreak of the disease in Warwickshire, Mr Reid narrows down the possible source of infection to imported meat. The butcher who supplied meat to the Shropshire farm received New Zealand lamb and Argentine lamb from his distributor. It is not known which kind of lamb the farm received, but New Zealand is free from foot-and-mouth whereas in Argentina the disease is endemic. The owner of the farm fed bones to his dogs and although he boiled them first he "did not claim that this was always done effectively". The disease first broke out in two gilt pigs and the bones fed to the dogs "could have been carried into the yard or neighbouring fields where the gilts had been". From this reconstruction of the crime, the report says, "it was not possible to establish conclusively that imported frozen lamb carried foot-and-mouth disease virus to the farm, but, as all other generally recognized sources of infection had been eliminated, it remained the most probable vector". The majority of subsequent outbreaks were probably the result of carriage by birds and the wind, but the large number of cases which occurred simultaneously over a wide area suggests a common primary cause. The Argentine lamb supplied to the Shropshire farm came from a consignment of 770 carcasses, all from a particular establishment in the Argentine, which was distributed over a wide area of the country. This was the area of the greatest concentration of the infection in the first month of the epidemic.

The only type of virus isolated in the epidemic was O_1. Although this type is prevalent in South America, it is not yet known whether it is prevalent in the area which supplies the establishment from which the suspected consignment was supplied.

How did the virus bypass the measures for its detection? The Argentinian Embassy in London has pointed out that there is a permanent veterinary staff attached to the British Embassy in the Argentine which collaborates with the local authorities in inspecting hygienic conditions in canning factories and slaughter houses. The staff was established on the recommendation of the Gowers Report, presented in 1954 after the last serious outbreak of the disease in Britain, but it has no power to sample carcasses intended for export to Britain for the disease. This, the British Ministry of Agriculture has stated, is the responsibility of the Argentinian Veterinary Service. It is impracticable to sample the carcasses coming into Britain because the heads and feet, which bear the most obvious signs of the disease, have been removed.

The most recent cases of the present epidemic occurred on February 21. The Ministry of Agriculture hopes that these will be the last, but is keeping its fingers crossed until the three-week incubation period of the virus has passed.

Carnegie Research

A review of the research being done at the six research departments of the Carnegie Institution of Washington is given in the institution's latest annual report for 1966–67. The departments concerned are the Geophysical Laboratory and the Department of Terrestrial Magnetism, both in Washington, DC, the Department of Plant Biology at Stanford, California, the Department of Embryology at Baltimore, Maryland, the Genetics Research Unit, Cold Spring Harbor, New York, and the Mount Wilson and Palomar Observatories, Pasadena, California, operated jointly with the California Institute of Technology

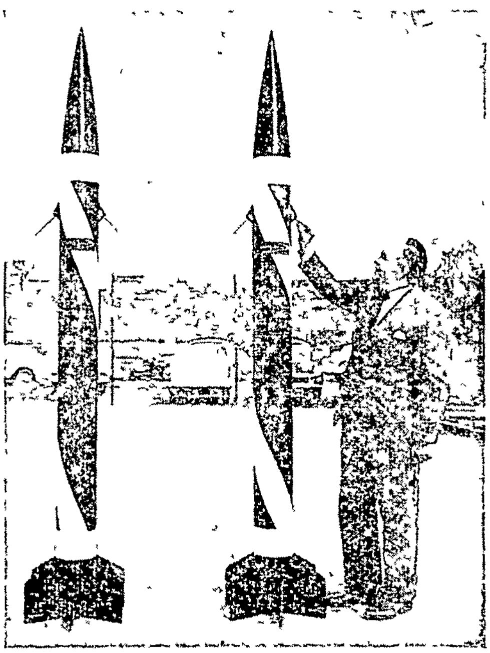
Research in the astronomical field during the year included the discovery of more information about quasars, and the discovery of a probable physical inter-galactic connexion between our galaxy and the Magellanic Clouds—scientists from the Instituto Argentino de Radioastronomía working at the radio telescope constructed by the institution at La Plata, Argentina, investigated what seems to be a bridge of neutral hydrogen between the Milky Way and the small Magellanic Cloud

Workers at the Department of Terrestrial Magnetism have found that the Earth's crust is very thin around Washington, DC They have constructed a map showing the thickness of the crust from North Carolina to central Pennsylvania The map shows that the crust varies in thickness from 30 to 60 kilometres, with the thinnest area underlying Washington and adjacent Virginia, and the thickest areas beneath the Appalachian Mountains. The Biophysics Section of this same department is interested in the biochemistry of evolution It has reported work on the search for repeated DNA sequences in different species representing all the main forms of life, from viruses to humans The investigators found that fifty-five different DNAs from plants and animals showed DNA sequence repetition In other words, in each case, a large fraction of the genetic material consists of many copies of short DNA sequences or packets of genetic information—only bacterial and viral DNA failed to show sequence repetition It is believed that the repeated DNA sequences are slowly mutated or changed during the course of evolution Thus the copies (members of families of repeated sequences) do not remain identical The degree of divergence may be a measure of the age of the family of nucleotide sequences—this divergence may be very relevant to evolutionary history From time to time certain segments of DNA are copied and new families of many identical members are produced

Among other research reported is the discovery at the Department of Plant Pathology of the way to make some common plants double their growth by reducing the amount of oxygen in the air surrounding them

New Research Rocket

THE proving trials of a new British research rocket have been completed and a series of test flights have started in which scientific experiments are carried The rocket is the Petrel, a small solid fuel vehicle designed to provide high altitude research facilities, mainly for universities, at low cost It was developed for the Science Research Council by the Ministry of Technology's Rocket Propulsion Establishment, the Atomic Weapons Research Establishment and Bristol Aerojet Ltd Petrel can reach altitudes of up to 140 km and can carry a payload of 13 kilograms, which has to be reduced if telemetry facilities are required



The first of the series of test flights was launched successfully on February 3 and a second firing took place on February 29, both from the South Uist range in the Hebrides The experiments carried on these flights were designed by the Radio and Space Research Station at Slough to investigate high speed electrons from space bombarding the atmosphere The flights were tests in the sense that their purpose was primarily to evaluate the behaviour of the rocket rather than to gather scientific information

Several more Petrel rockets are planned to be launched from South Uist this spring, carrying experiments for university research groups These include payloads from Birmingham University to investigate ions and electrons in the atmosphere, from Southampton to study sporadic layers of ionization and from Sheffield to study fine structure effects in the ionosphere

Rules for Heart Transplants

THE Board on Medicine of the US National Academy of Sciences has issued a set of guidelines for heart transplants In a statement published on February 28 it says that because cardiac transplantation in man cannot yet be regarded as an accepted form of therapy, but only as a scientific exploration of the unknown, the operation should only be carried out in institutions where a special set of criteria can be met The surgical team, the statement says, should have extensive laboratory experience of heart transplantation and a thorough understanding of the biological processes involved in rejection and its control—immunologists should be readily available to collaborate in the operation

The statement goes on to say that the primary justification for transplanting hearts, with respect to donor and recipient, is that the knowledge so gained will be of benefit to other members of society The ethical issues involved are part of the whole problem of the ethics of human experimentation, which are at present being studied intensely, as the statement says, by a number of well-qualified groups in the United States and other countries Until some ethical guidelines are available the Board on Medicine can only advise every institution to assure itself that it has protected the interests of all parties involved to the fullest possible extent. The donor, the board says, should be unanimously selected by doctors who are not directly involved in the transplantation effort Their opinion as to the acceptability of the donor should be based on crucial and irreversible bodily damage and imminent death The prospective recipient should also be examined by an independent group of doctors, including a cardiologist and an immunologist Their decision should be based on all the evidence, including the presence of advanced, irreversible cardiac damage and the likelihood of benefit from the procedure

School Leavers

VOLUME 2 of *Statistics of Education*—one of at least five volumes covering different educational subjects—has been published this week by HMSO (price 20*s*) This particular volume deals with General Certificate of Education examinations, Certificate of Secondary Education examinations, and school leavers

From the numerous lists of figures, a rising trend in the number of students qualified in GCE can be seen In fact, during the ten years ending in 1966, the number of passes at O-level almost doubled The biggest increases were in economics (and associated subjects)—490 per cent—and in the other social science and vocational subjects group—200 per cent Naturally enough, the greatest number of entrants were in English and mathematics, with geography and French not far behind Physics also seems to have been popular, with an average of 54 7 per cent passes Successes in the A-level examinations showed an increase of nearly 150 per cent during the last decade and the only decrease was in botany which fell by 9 per cent English literature and physics were the two most popular subjects The total of 140,000 CSE candidates for 1966 was more than twice the number for 1965, with entries for boys averaging 4·3 subjects each and for girls 3 2 subjects each

In 1965–66, 38 5 per cent of all leavers attempted O-level, and of these 21 per cent obtained five or more passes Of over 15 per cent who attempted A-level, 11 per cent obtained two or more passes The data also show that 16·5 per cent of leavers went on to further education 7 5 per cent each to universities and to other full-time further education, and 1 5 per cent to colleges of further education

Regional statistics show that the proportion of all leavers going to full-time further education was above the national average in Wales and in the south of England except Greater London, and that the number leaving with two or more A-levels was highest in south-east and south-west England A similar trend was shown for those leaving with five or more A-levels, with a percentage of 24 7 per cent for Wales closely following the figures of 26 8 and 26 4 for the south-east and south-west respectively

Committee on Education

THE British Parliament has now proceeded with the plan to set up a specialist committee of the House of Commons to deal with educational topics The membership of the committee, announced last week, includes ten Labour members, seven Conservatives and no others, a source of some frustration to the dozen Liberals in the House of Commons As well as being large, the select committee is also eminent. It includes a former Conservative Minister of Education, Sir Edward Boyle, and a former Labour Minister, Mr Fred Willey, who was Minister of Land and Natural Resources until that ministry disappeared Before that he was for many years a Labour spokesman on education The Labour Party, with almost as many teachers in the House of Commons as the Conservatives have lawyers, ran the risk of turning the committee into little more than a teachers' lobby. This seems to have been resisted, although several of the members are former teachers—Mr Christopher Price, Mr Trevor Park and Mr Richard Mitchell have all taught at schools, and Mr Stanley Henig is a former university lecturer Among the Conservatives there are no former teachers, except Mr Richard Hornby, who taught for two years at Eton There is, however, Mr Esmond Wright, who until his election as member for Glasgow Pollock was professor of modern history at the University of Glasgow

The final terms of reference of the committee are a compromise In its original form, the motion establishing the committee put down by Mr Richard Crossman, Leader of the House of Commons, did not mention Scotland, and the committee had no Scottish members This was later changed, and the committee is now empowered to examine the activities of the Scottish Education Department as well as the Department of Education and Science It now has two Scottish members But this has not satisfied members from Scotland, who are hard to satisfy They say, quite truthfully, that Scotland has an entirely separate system of education, and deserves a committee to itself—a committee empowered to examine the work of the Scottish Office as a whole

Mr Crossman has made it quite clear that the committee is not a committee on education. Rather, it is a committee charged to examine the activities of the Department of Education and Science and the Scottish Education Department—it is a departmental rather than a subject committee. Mr Crossman already seems halfway to admitting that it was a mistake to establish the committee on this basis "It is arguable that subject committees are, on the whole, better and easier to work It may be in the final resort that we come only to subject committees, but we were pledged to try out a departmental committee " There is now a select committee on agriculture and one on education, both organized on departmental lines This has been done, it is thought, because Mr Anthony Crosland and Mr Fred Peart were the two ministers initially most enthusiastic about specialist committees Mr Crosland has now moved on to the Board of Trade, leaving Mr Patrick Gordon Walker, still having an unhappy time as a minister, to handle the select committee as best he can Mr Peart, still Minister of Agriculture, is probably finding the committee on agriculture more of a problem than he bargained for.

The committee will be meeting in public, and its chairman will be Mr Fred Willey As its first subject, it has chosen to examine the Inspectorate of Schools This is the body which certifies the standards of all schools in Britain, and is likely to prove a tepid subject politically The committee has clearly decided to play itself in gently, and is likely to start the examination by summoning civil servants rather than ministers from the Department of Education and Science

New Degrees

RIPPLES from the permissive society are beginning in Britain to be felt in the strict world of the PhD degree, where ordinances are being revised Bristol is the latest university to relax its requirements so that graduates of Bristol of eight years standing can now submit "substantial published work pursued in the university or elsewhere" for a PhD These conditions supplement and do not replace the conventional supervised postgraduate work in the university

Other universities have already introduced similar schemes That at Cambridge has been in action for more than a year and a considerable number of applications and enquiries has been received The idea is to provide some kind of recognition for the work that individuals, such as teachers or industrial research workers, have published, often as a result of studies in their spare time

Mathematics for All

ONE of the principal recommendations of the Dainton Report, published on February 29, is that all pupils should study mathematics until they leave school It seems from the report that a high proportion of pupils with O-level passes in this subject abandon it in the sixth form, but the Dainton Committee suggests that the overwhelming majority are capable of benefiting from its continued study It considers that mathematics is a "key factor" in restoring flexibility to the present situation, and stresses that England and Wales are exceptional in western Europe in abandoning science and mathematics for a significant proportion of those in school over the age of 15

One difficulty with this proposal may be the shortage of science teachers paragraph 86 of the report itself states that there is a shortage—especially in mathematics How then is mathematical teaching to be increased when teachers are themselves in short supply ? The latest available figure for the number of mathematicians whose qualifications can be regarded as equivalent to a degree who are teaching mathematics in schools is 11,033 for 1965—an increase of only 252 over the figure of 10,781 for 1962 Moreover, in a sample of secondary schools, 36 per cent of mathematics teaching was given by teachers with no qualifications in mathematics But the report stresses that the way in which these teachers are used and the support they are given is probably as important as their actual supply It also emphasizes the encouraging fact that recent policies for the recruitment of young scientists into teaching have been quite successful, a survey in 1965 showed that 40 per cent of science teachers (including mathematics) with second class honours were under 30 compared with 33 per cent for languages

Dr Bryan Thwaites of Westfield College, this year's president of the Institute of Mathematics, feels sure that the various professional institutes will back up the proposal, and maintains that it is right both educationally and from the point of view of manpower supply He is surprised, however, at the committee's assurance that the quality of science teachers is being maintained, instead of declining In his experience, at least one headmaster has suggested that he could not obtain science teachers of sufficiently high quality

EMPLOYMENT OF MATHEMATICS GRADUATES IN MAINTAINED AND DIRECT GRANT SCHOOLS—UNIVERSITY GRADUATES ONLY

	1962	1963	1964
1st class honours	512	504	507
2nd class honours	1,523	1,581	1,663
3rd class honours	3,445	3,434	3,432
Total	5,480	5,519	5,602

The headmaster of the City of Bath Boys' Grammar School, Mr L H Scott, thinks that "everyone ought to know the language of mathematics", but thinks that a great many pupils will not be willing to be pushed into it He emphasizes the necessity for a new type of course, particularly in the sixth form Like Dr Thwaites, he believes that there is a definite fall in the quality of science teachers and expressed concern that the shortage is likely to become more acute within the next ten years—a study of the age distribution of teachers has shown that a high proportion of those with first class honours are approaching retirement He thinks that teachers in this age bracket are still to a large extent holding the fort

Professor Sir Nevill Mott of the University of Cambridge is also an advocate of a new mathematics course What the report fails to bring out, he suggests, is that pupils are unlikely to study mathematics beyond O-level unless they are good at it, for the simple reason that they do not think it will help them in securing a university place He suggests that there should be a new, less advanced mathematics course which makes use of mechanical aids and films, and that universities should be encouraged to accept reasonable performance in such a subject offered by pupils hoping to read biological subjects at university

Parks and Countryside

THE eighteenth report of the National Parks Commission for the year ended September 30, 1967, has recently been published (HMSO, 8*s*. 6*d*) This is probably the last time that the report will appear in its present form, for the commission's functions will be altered when the Government's Countryside Commission comes into being—though when this will be is uncertain, for a parliamentary standing committee is still considering the Countryside Bill which had its second reading in November 1967 The National Parks Commission, which reports to the Minister of Housing and Local Government and the Secretary of State for Wales, gives the impression in its report that it does not welcome the proposed Countryside Commission with open arms—"it seems certain that the Bill will not give us all that we asked for in the way of financial and executive independence " The commission, however, "looks forward" to the wider responsibilities implicit in the new Bill

At present, the National Parks Commission is continuing its job of preserving the ten National Parks and other "areas of outstanding natural beauty" in England and Wales Last year, orders designating two new areas—Anglesey and the South Hampshire coast—were made by the commission, and plans were advanced for further areas including the Kent Downs, the Norfolk coast and Dedham Vale Some of these orders have since been confirmed Early in 1967, when a large estate in the heart of the Snowdonia National Park came on to the market, the commission urged the Government to purchase an area to which public access could be secured Though the estate was sold privately, the Secretary of State for Wales announced in November 1967 that the Government had purchased from the new owners a critical area of some 13,000 acres including the summit of Snowdon and Llanberis Pass. The Countryside Commission will replace and extend this work of the National Parks Commission in the context of the promotion of the countryside generally The National Parks Commission seems to think, however, that the National Parks will continue to occupy a central position in the new organization The progress made in each park during the year is recorded in the report

During the year under review, links with the Council of Europe were strengthened by the appointment of the National Parks Commission as the United Kingdom correspondent to a new European Information Centre on Nature Conservation As a result of the work of the Standing Committee set up by the second "Countryside in 1970" conference, the commission has also been invited to act as the United Kingdom "focal point" for all information activities relating to the countryside

One of the functions of the commission is to make proposals for the creation of long-distance footpaths and bridleways In this connexion the commission submitted information and recommendations to the Committee on Footpaths appointed by the Government in 1967. An important job of the commission is the consideration of proposals for development affecting the landscape in designated and other areas of coast and countryside During the year, 302 such proposals were considered, of which one-third were within areas of outstanding natural beauty One of the most important of the proposals was one for a North Sea gas terminal at Bacton on the Norfolk coast (see *Nature*, **217**, 10, 1968) At the public inquiry, at which the commission was represented, the Minister of Housing and Local Government agreed that the works proposed would involve "a massive and alien intrusion into the coastal landscape". He allowed the development, however, to the "great distress" of the commission The commission points out that the inquiry did at least establish the technical possibility of taking sea gas treatment plant away from the coast, previously considered impractical

Science in Parliament

The Parliamentary and Scientific Committee, an organization which sets out to keep both Houses of the British Parliament informed on scientific and technological subjects, has elected a new chairman He is Mr David Ginsburg, Labour Member of Parliament for Dewsbury since 1959, and he takes over from Mr Arthur Palmer Mr Ginsburg, who is 47 this year, was educated at University College School and Balliol College, Oxford, where he got a degree in politics, philosophy and economics For some years he was secretary of the research department of the Labour Party. Mr Ginsburg, whose political views are in the mainstream of the Labour Party, has been a member of the Select Committee on Science and Technology since its formation His contributions to the sessions of the committee are always pleasant and well informed, which suggests that he is admirably equipped to be chairman of the inter-party Parliamentary and Scientific Committee

Parliament in Britain

from our Parliamentary Correspondent

Mr Robert Woof, a mining Member of Parliament, won a tiny victory on February 23, when he asked the Minister of Power which nuclear power station he expected to be producing electricity at 0·54*d* per unit by 1970. Mr Marsh had to admit that none would, and was generous enough to point out that the best coal-fired stations, Ratcliffe and Cottam, coming on stream in 1968, would generate at 0 54*d* and 0·56*d* per unit respectively Dungeness B, the advanced gas cooled station due to start in 1971, would produce power at 0 57*d* per unit (Written answer, February 23)

Concorde

Mr Wedgwood Benn, Minister of Technology, announced approval for the production financing of the Concorde supersonic airliner The amount of money would be large, he warned The net working capital needed over the next five years would be of the order of £100 to £125 million, and the companies were arranging for their banks to advance up to £25 million, which the Government would guarantee Mr Benn said that the rate of production would be three a month, although it depended to some extent on firm orders Only Mr Hugh Jenkins struck a dissident note Did the minister not agree that the proposal was a gross misuse of public funds ? That depended, Mr Benn said, on whether it was a success If it was a great success, he said, it would be a profitable investment (Statement, February 27)

Bristol Siddeley

Later in the week, Mr Benn made a statement about the report of the committee of inquiry into the pricing of contracts made with Bristol Siddeley Engines The committee, under Sir Roy Wilson, said that the company had budgeted for, and achieved, exorbitant profits on overhaul contracts "The approximate extent of the profitability on these contracts was, at the time, known to the company at all levels of management We do not accept that the overcharging has been justified by any of the arguments put forward by the company " The negotiations amounted to intentional misrepresentation, despite this, Mr Benn said that the Attorney General, after consultation with the Director of Public Prosecutions, had decided that the evidence did not justify proceedings The company had already paid back some £3 96 million (Oral answer, February 27)

Chapelcross Breakdown

Mr Tom Swain asked the Minister of Technology how long it would be before the nuclear reactor at Chapelcross would be in operation again It was shut down after an accident in May 1967. Mr Benn said that remedial work was making good progress, but the Atomic Energy Authority could not say how soon the station would be back on stream The loss of sales of electricity up to the end of February had cost £0·8 million Mr Benn also told Mr Swain that the growing volume of exploration work should ensure enough uranium for the United Kingdom nuclear power programme at reasonable prices A price variation of 10 per cent meant a change of 1 25 per cent in generating costs, he said (Written answer, February 29)

NEWS AND VIEWS

Biosatellites are a Waste of Money

THE National Aeronautics and Space Administration (NASA) is currently asking the United States Congress for $32 5 million to finance bioscience programmes during the fiscal year 1969 It is perhaps no coincidence that NASA also convened a symposium at the National Academy of Sciences in Washington on February 23 and 24 to publicize the preliminary results of the Biosatellite II mission, even though the data from most of the experiments were still only incompletely analysed and essential post-flight controls had not even begun That might not have mattered, of course, if there had been particularly exciting results But there were not, and the proceedings of the symposium are unlikely to win the biosatellite programme many new friends among the scientific community Indeed, they give more ammunition to the many and eminent biologists who believe Biosatellites I and II were a waste of money and time Congress, however, even though it is cutting the budgets of many government agencies, may not think the same way

Biosatellite II was essentially a repetition of Biosatellite I, which was successfully launched in December 1966 but which, because of a failure in retro-rocket ignition, was not recovered And as the NASA engineers and administration explained in the first session of the symposium, Biosatellite II has also had its technical problems First, during the final count-down on September 7, 1967, there was a delay of about three hours because of minor faults in the spacecraft and launching vehicle which unfortunately meant that the biological experiments were kept on the Earth three hours longer than expected This greatly reduced the value of an experiment with fertilized frogs' eggs Second, although the satellite was successfully launched into a nearly circular orbit at 315 km, the planned three-day flight had to be curtailed to 45 hours because of a storm threatening the recovery area in the Pacific so that the experiments were not run to completion. Third, and most important, the vibrations to which the satellite was subjected during the launch were apparently greater than anticipated, so that the pre-launch controls of the effects of vibration and acceleration on the experiments have to be repeated at the Ames Research Center beginning on March 12

The thirteen experiments which were flown in Biosatellite II were apparently selected from some two hundred proposals submitted to NASA, and they fall into two main classes First, those designed to study the effect of weightlessness (or, more accurately—at least until the effects of vibration have been cleared up—space flight conditions) on the growth and development of the plants and frogs' eggs The rationale behind these experiments is clear, because both plant growth and frog embryogenesis are known to be sensitive to gravity The second class of experiments was designed to tell whether organisms are more deleteriously affected by radiation under space flight conditions than on Earth Presumably the experimenters argued that if weightlessness has any effect on cellular metabolism, this might show up as an increased mutational rate which is indicative of an upset in the cellular repair mechanisms

Without going into great detail—the full symposium proceedings are to be published in *Bioscience* later this year—the results of the first class of experiments involving plants can be summarized briefly All the responses during the flight, the epinasty of pepper plants, the growth and orientation of wheat root and coleoptiles, the behaviour of the so-called statolith starch granules in wheat seedlings as revealed by histochemistry and the distribution of a few enzymes in wheat seedlings, also occurred in controls on klinostats on the Earth's surface As Dr K. V Thimann, the general chairman of the symposium, said in his summary, there is no real basis for believing that zero gravity causes any responses different from those due to balanced gravity Equally, space flight has no effect on an experiment to measure the growth, feeding and cell division of the multinucleate amoeba *Pelomyxa carolinensis*

Perhaps the most interesting experiment flown on Biosatellite II was the one intended to find out whether frogs' eggs (sp *Rana pipiens*) develop normally under zero gravity Since Schultze's classic experiment in the late nineteenth century, evidence has accumulated that gravity plays a part in determining bilateral symmetry and normal development of the embryo The stage of development most sensitive to disorientation with respect to gravity is immediately after fertilization, and sensitivity decays steadily during the onset of the first cleavage The best experiment for Biosatellite II would clearly have been to fertilize the eggs in space This apparently was too difficult, so eggs were fertilized before launch, held at 6° C and then heated in space Unfortunately, the three-hour delay in the launch was critical to the experiment It meant that by the time the eggs were in orbit, they had reached the middle of the first cleavage stage, although they had not completed cleavage The result of the experiment was that the eggs developed quite normally from this stage during the flight and subsequently after recovery Weightlessness and the vibrations during launching do not therefore affect development beyond the first mid-cleavage stage That is not a trivial statement, but because of the three-hour delay the most gravity sensitive period in development was not tested

The six experiments designed to test for an enhancement-effect between radiation and space flight conditions involved a fairly wide range of organisms two plants, *Tradescantia* and *Neurospora*, and three insect species, *Drosophila*, the flour beetle *Tribolium*, and a parasite wasp *Habrobracon* As expected, the response of cells to radiation in space flight varies greatly from one type of cell to another depending on the metabolic state of the cells, just as on Earth. But what was not expected was that there does seem to be a slight but statistically significant increase in the sensitivity of some cells to radiation damage under space flight conditions The biggest effect detected was with *Drosophila* scored for ' dumpy wing" mutation The flight group had 14 mutants out of the total 20,562, whereas the ground control had 4 mutants out of a total of 24,838 Strontium-85 in the satellite was the source radiation in all these experiments

These radiation experiments at first sight do suggest that weightlessness has some enhancing effect on radiation damage, but the interpretation is complicated because vibration or some other factor in the space flight environment may be responsible Clearly there can be no definite conclusion until thorough post-flight vibration tests have been performed at the NASA Ames Laboratory And NASA might be more highly respected if, in its public statements on Biosatellite II, it had not tried to gloss over this and other problems NASA blandly asserts that "the only condition flight organisms experienced was weightlessness", yet Dr O E Reynolds, Director of Bioscience Programs, in his summary of the symposium in Washington, said the immediate problem was to clear up the vibration radiation interaction problem which he described as the "muddiest issue" Similarly, the NASA public statement asserts that "all 13 experiments carried on the satellite were successful", but does not mention the critical three-hour delay which greatly reduced the significance of the experiment with frogs' eggs

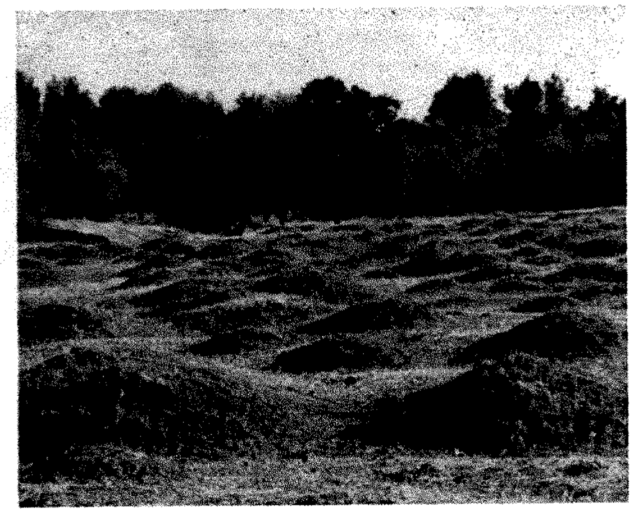
Have the results of the Biosatellite II justified the cost of the mission ? And what implications do they have for future biosatellite programmes ? Dr C A. Wilson of the Ames Research Center, who was in charge of the launchings of Biosatellites I and II, estimated that about three-quarters of the NASA bioscience programme budget was being spent on biosatellites and that the combined cost of Biosatellites I and II was $50 million But according to at least one of the experimenters, this is a conservative estimate Obviously it is impossible to get a unanimous decision about how much money any particular scientific fact or piece of research is worth, but the $50 million NASA has spent has really shown only two things First, zero gravity and balanced gravity have the same effect on plant growth and development, and, second, that some factor in the space flight environment appears to enhance the deleterious effect of radiation on some cell types There is always the argument that it is impossible to predict the effects of space flight, so the experiments had to be done once But how many biologists honestly believed that $50 million would not have produced far more significant information if it had been spent by the National Science Foundation, the National Institutes of Health or even on the exobiology sponsored by NASA ? Dr Thimann must surely have been voicing the thoughts of most American biologists, including many of the most eminent, when he said forthrightly at the end of the symposium that there was no real basis for requesting further flights carrying experiments similar to those on Biosatellite II Unfortunately, that is unlikely to deter NASA

What implications do the results of the Biosatellite II have on the four biosatellites that are scheduled for flight in the next three years ? Dr Reynolds said there was nothing in the results of Biosatellite II which suggested to him that the experiments already scheduled for the next four flights should be changed That may well be true for the two thirty-day missions to study the physiology of Macaque monkeys during space flight Those are legitimate experiments in which the bioscience programme could contribute significantly to the manned space flight programme, space medicine and basic physiology What other justification can there be for the biosatellite programme, especially at a time when the budgets for NSF and NIH are being held back ? The two other flights already planned, however, are for 21 days, and two of the proposed experiments must surely be critically re-examined The first is to observe the morphogenesis of the plant *Arabidopsis thaliana* under weightless conditions, and the second is to study the effect of weightlessness on human cells in tissue culture In the light of the Biosatellite II results, can either of these experiments be justified ? If NASA really wants its biosatellite programmes to be taken seriously by the scientific community, and that is certainly not the case so far, it would do well to abandon both these experiments, possibly replacing them by a proper experiment on frog embryogenesis with fertilization during flight If NASA perseveres with its biosatellite programme unchanged, it can only expect that most biologists will remain determined not to be associated, no matter how big a financial carrot is dangled in front of them

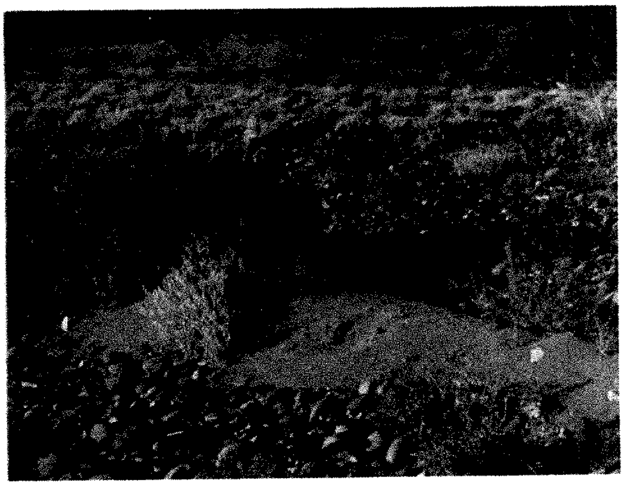
Earth Mounds

PICTURES of sand dunes formed in the lee of a hedge during a Yorkshire dust storm and reproduced recently in *Nature* (**216**, 20, 1967) have stimulated Harold A Gangmark and F Bruce Sanford of the United States Bureau of Commercial Fisheries, Seattle, to write in support of their theory for the formation of earth mounds (*Fishery Bulletin* Vol 6, No 1) These earth mounds can be found in the flood zones of rivers in many parts of America and probably other parts of the world, but none of the many theories of how they are formed has yet been universally accepted. Mr Gangmark and Mr Sanford, as fishery biologists, are interested in flooding and soil erosion because of the effect on fish and incubating spawn, and believe that an explanation of the way in which mounds are formed will indicate how streams behave and which one will be most suitable for fish rearing.

Plants such as brickellbush growing in the flood path of a stream are believed by Mr Gangmark and



Mounds near Red Bluff, California.



Silt being deposited downstream of a plant.

Mr Sanford to be the primary cause of the mounds. During flooding, the plants slow down the stream to such an extent that the mud being carried along is deposited and a pile of silt builds up in an elongated shape downstream from the plants. The stream flow produces ellipsoidal mounds with their axes parallel in the direction of flow. Any plant in a flood plain is thought to produce the beginnings of a mound, but only brickellbush and other plants with strong roots and long lifespan will stand up to continuous pressure to form large mounds, some of them more than three feet high and twenty feet long. Mounds have been found in places where streams no longer run, even when in flood. In many cases this change of environment kills the plant which caused the mound, leaving no visible remains, but Mr Gangmark and Mr Sanford have found old roots at the upstream end of all the mounds investigated.

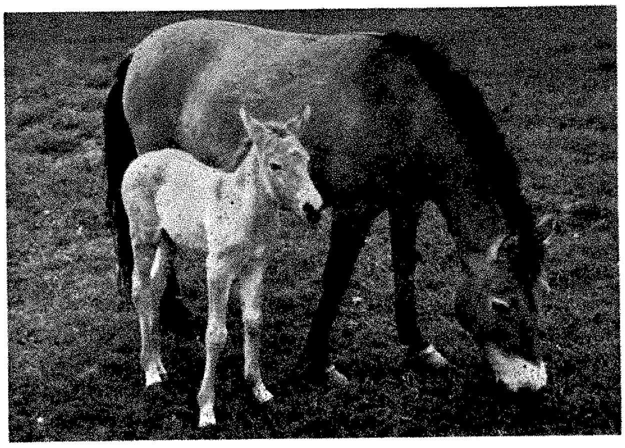
This theory for the method of formation of the mounds is reinforced by comparison with the dunes formed in dust storms. The transport medium is different: air for dunes and water for mounds, but the dunes build up in ellipsoidal shapes behind clumps of hedge like large-scale mounds, suggesting that the methods of formation are similar.

Rare Horses

THE Przewalski horse, one of the rarest mammals in the world, has excited interest for several reasons. It is believed to be the horse pictured in the Caves of Lascaux by Stone Age man ten to fifteen thousand years ago and it is considered by most authorities to be the ancestor of modern breeds. At one time herds roamed wild over Europe and Central Asia, but the numbers gradually declined as civilization spread. The modern form was found less than a century ago, in 1879, by Colonel N. Przewalski in a restricted area in the region of the Gobi Desert on the borders of China and Outer Mongolia.

It was named *Equus przewalskii* by Poliakof in 1881 to distinguish it from the modern domestic horse, *E. caballus*. Unfortunately, once discovered, the numbers of Przewalski horses in the wild declined further. Many were captured and sent to zoos. Quite recently it was thought that the truly wild horse had become completely extinct and the species was only to be found in captivity—even those in zoos are not all true Przewalski horses, because many of those originally captured were thought to have been hybrids between Przewalski horses and Mongolian ponies run wild. There may still be some horses left, however, for in 1966 a herd of eight (a stallion and seven mares) was sighted in Mongolia near the Chinese border. Unfortunately, the herd galloped off into China and so little may be known about it for some time. Several skeletons of course remain, and zoos have bred from the original captured horses. The latest *International Zoo Yearbook* gives figures of 64 male and 83 female Przewalski horses living in 35 zoos between February and August last year. The mare and foal pictured here are in the Zoological Society of London's garden. The foal was born in 1966, but it is not certain whether it is a true Przewalski horse as it has a lighter mane and tail than usual.

There have been several papers and books written on the Przewalski horse and its phylogenetic relationships. The Prague Zoo has been outstanding in keeping records of the horse, and a pedigree book is compiled there every year. Dr R. M. Stecher of the Western Reserve Medical School, Cleveland, Ohio, has been particularly concerned with the anatomical characteristics of *E. przewalskii* which distinguish it from other Equidae. In a recent paper (*Acta Zoologica et Pathologica*, No. 43, 45 ; 1967) he gives results of vertebrae



Przewalski mare and foal (The Zoological Society).

counts from spines of 61 skeletons of the Przewalski horse and he correlates these with counts from four other horses—the domestic horse (*E. caballus*), mule (*E. caballus* × *E. asinus*), donkey (*E. asinus*), and hemione (*E. hemionus*). He has found that Przewalski horses are differentiated from other Equidae by having the longest thoracic segment of the spine, the next-to-the-longest lumbar segment, the shortest sacral segment and the next-to-the-smallest number of lateral joints in the lumbar region. Stecher attempts to correlate the spinal characteristics of the five horses with their chromosomal complements. The chromosomal counts of the horses are found in the following descending order: Przewalski horse $2n=66$, *E. przewalskii* × *E. caballus* $2n=65$, *E. caballus* $2n=64$, *E. caballus* × *E. asinus* $2n=63$, *E. asinus* $2n=62$, and *E. hemionus* $2n=54$. Stecher has found that there is a complete correlation between the decreases in chromosome counts and the decrease in presacral vertebrae. There is also a partial correlation with the increase in the anatomical as well as the functional length of the sacrum, additions to the functional length of the sacrum by ankylosis of caudal vertebrae, and the increase of lateral joints in the lumbar region. It may be, therefore, that in the course of equine evolution the chromosome number and the number of presacral vertebrae have decreased, and the numbers of sacral vertebrae and lateral joints have increased.

More Plant Taxonomy

Some of the latest developments in plant taxonomy were discussed on March 1 when the Experimental Plant Taxonomy Group of the Linnean Society held its tenth annual symposium.

The section Eu-Cochlearia of the genus *Cochlearia*, scurvy-grass, has always given trouble; Linnaeus described four species and since then there has been considerable taxonomic confusion. Mr J. J. B. Gill of the department of genetics in Liverpool has been investigating cytologically the relationships between thirteen species of *Cochlearia*. Within these species chromosome numbers of 12, 14, 25, 26, 36, 42 and 48 occur, and Mr Gill has found that hybridization between chromosome levels is easy, except when crosses are made between diploids ($2n=12$ or $2n=14$) and octoploids ($2n=48$). Analysis of chromosome pairing in hybrids showed Mr Gill that all the diploid species which he examined are essentially the same; the species with two sets of seven chromosomes have arisen from those species with two sets of six, by aneuploidy—one chromosome has been added to the basic number of six. Evidence for this comes from intercrossing these species, when at meiosis the chromosomes show three pairs and one trivalent or six pairs and one univalent.

Mr Gill found that all thirteen species of *Cochlearia* are related, and that autoploidy has been very important in their evolution. For example, *C. officinalis* ($2n=24$) when crossed with a $2n=12$ species shows between one and six trivalents, and in a cross between two populations of *C. officinalis*, one from Sweden and the other from Italy, there was strong secondary association of bivalents. This clearly suggests that *C. officinalis* developed by autoploidy from a $2n=12$ species.

Miss Brenda Matfield of the department of botany at Westfield College, London, has been hybridizing species of the sub-series Tormentillae of the genus *Potentilla*. The species concerned are *P. reptans* ($2n=28$), *P. erecta* ($2n=28$) and *P. anglica* ($2n=56$). The last is thought to be an alltetraploid of the other two—at meiosis it shows only trivalents—but Miss Matfield has so far been unable to synthesize it. Hexaploid natural hybrids are common and three have been given binomials: *P.X. suberecta* (*P. anglica* × *P. erecta*), *P.X. italica* (*P. erecta* × *P. reptans*) and *P.X. mixta* (*P. anglica* × *P. reptans*). Experimental hybridizations have indicated that *P.X. mixta* may arise in two ways, by hybridization between *P. anglica* and *P. reptans*, or by the fusion of an unreduced gamete of *P. reptans* with a reduced gamete of *P. erecta*. Miss Matfield has shown, by backcrossing *P.X. suberecta* with the parent species, that introgression is theoretically possible from *P. erecta* to *P. anglica* through the hybrid, although this is not known in the field.

Attempts to hybridize *P. erecta* and *P. reptans* were unsuccessful, and Miss Matfield suggests that *P.X. italica* is not a separate species and that the name is a synonym for *P.X. mixta*—the descriptions for the two are very similar.

Dr M. J. Lawrence, Dr J. S. Gale and Mr A. E. Arthur at the department of genetics in Birmingham have been investigating the causes of genetic diversity in *Papaver dubium*, the long-headed poppy. The character which they have studied is time of flowering, and for the purpose they set up a synthetic natural population in 1964. In this, natural conditions were simulated as nearly as possible—hand raking and light weeding were carried out in the autumn, but no fertilizer was used. Outbreeding was dismissed as a possible cause of genetic diversity when no overall difference between the mean expression of flowering time was found between crossed and selfed progeny of seven plants sampled from this population. The possibility that genetic variation is a result of environmental heterogeneity of habitat was also discounted when poppies were sampled from a fairly wide climatic range and showed no correlation of climate with flowering time.

The third possible cause of the genetic diversity is selection, and Dr Lawrence and his colleagues have found that this is the operative factor. They found that early flowering poppies seem to be the fittest in that they produce the most viable seed, but populations do not become uniformly early flowering because dormancy is also involved.

Some of these poppies germinate in the autumn and some in the spring, and many of the former are the early flowering types. Thus when the winter is mild and many autumn germinators survive, these will be the fittest, but when the winter is severe there will be more spring germinators, and these, which will in this case produce the most viable seed, will be the fittest. Because the selective advantage fluctuates from one season to another, progress towards the fixation of one genotype with respect to flowering time is retarded and genetic diversity is maintained.

Voltes Face

from our Molecular Biology Correspondent

Last week (*Nature*, **217**, 803; 1968) I described three papers dealing with the sub-unit structure of aspartate transcarbamylase and its relation to the function of the enzyme The central finding (Gerhart and Schachman, *Biochemistry*, **7**, 538, 1968) was that there are six subunits, two bearing catalytic and four bearing regulatory sites This unique situation was considered in terms of an allosteric scheme for the enzyme Hard on the heels of these papers comes a study of the same enzyme by Weber (*J Biol Chem*, **243**, 543, 1968) from which it appears that these results are in error, inasmuch as aspartate transcarbamylase has in fact a rather more commonplace constitution, being made up of four regulatory and *four* catalytic sub-units

Whereas Gerhart and Schachman worked with the fragments obtained when the enzyme is dissociated by treatment with an aromatic mercurial, and assumed these products to represent monomeric chains, Weber performed molecular weight determinations in 8 M urea Sedimentation equilibrium led to values of some 42,000 and 23,000, respectively, for the catalytic and regulatory chains These results were supported by N-terminal residue determinations and amino-acid analysis one N-terminal alanine and one threonine were found for an equivalent weight of 73,000, and the amino-acid compositions for the two sub-units together reproduced closely the composition of the intact enzyme It therefore now seems safe to conclude that the protein is an octamer and that the catalytic and regulatory chains each possess one active site The number of sites (four of each kind in the native enzyme) was reported by Changeux, Gerhart and Schachman, who have discarded an earlier estimate of eight regulatory sites

The moral yet again would seem to be that it is hazardous and unnecessary to assume that monomeric chains are present under any but extreme denaturing conditions Numerous molecular weight determinations of proteins in guanidine hydrochloride solutions—the use of which has been urged notably by Tanford and by Harrington—are now known to have given correct monomer molecular weights, and it is, one must suppose, an indication of the success of this approach that its re-discovery on this side of the Atlantic should already have been described (Ullmann, Goldberg, Perrin and Monod, *Biochemistry*, **7**, 261, 1968)

It may be mentioned that Sia and Horecker (*Arch Biochem*, **123**, 186, 1968) are now in agreement with the four-chain structure of the enzyme aldolase, long a subject of contention They elaborate, moreover, on the remarkable degradation of the polypeptide chain of this enzyme in quite mildly acid solution The possibility that such phenomena may seriously vitiate molecular weight determinations in special cases must be recognized

T_4 Regulation

from our Cell Biology Correspondent

DURING the replication of T-even phages, gene functions appear in a time sequence, which is why most viral functions have been classified as either early or late Refinements in methods of analysis have, however, shown that this is an oversimplification Levinthal, Hosoda and Shub, for example, have found that early proteins are synthesized asynchronously, they are not a single co-ordinately controlled set There are also sequential changes in the population of phage *m*RNA molecules (see *Nature*, **216**, 117, 1967) But only recently, with the improvements in the sensitivity of DNA/RNA hybridization techniques, has it been possible to measure accurately gene control at the level of *m*RNA transcription In *J Mol Biol* (**31**, 325, 1968), Bolle, Epstein, Salser and Geiduschek describe DNA/RNA hybridization experiments which begin to show the complexity of the regulation of T_4 transcription

Twenty minutes after infection, a third to a half of the phage *m*RNA molecules are late *m*RNA species The remainder of the population of *m*RNA at 20 minutes consists of early-type molecules which are also present 5 minutes after infection, when the late species are between a hundred and several thousand times less abundant There is no difference in the average stability of early and late *m*RNA It is also clear that the whole T_4 genome is not translated for a brief period immediately after infection, some late species seem not to be made at all in the first 5 minutes after infection Bolle *et al* also mention briefly other results to be published in detail later Apparently there are three classes of early *m*RNA molecules which are turned on rapidly in succession during the first 5 minutes of infection Synthesis of the majority of these RNA species is then reduced several-fold after between 5 minutes and 20 minutes, during the period in which the late *m*RNAs are switched on Even so, a few of the RNA species present after 5 minutes increase during this period

It is clear that regulation of T_4 gene expression cannot be solely at the translational level, and the most reasonable explanation of the 200 to 4,000-fold increase in late *m*RNA between 5 and 20 minutes is that late *m*RNA transcription is specifically switched on in this period What the switch mechanism is and whether all late genes are activated at the same time remains to be seen

In the same issue of *J Mol Biol* (**31**, 463, 1968), Chrispeels, Boyd, Williams and Neidhardt report that during T_4 infection of *E coli*, a new valyl *t*RNA-synthetase activity appears with an accompanying decrease in the amount of the original *E coli* valyl *t*RNA-synthetase The T_4 induced enzyme differs in sedimentation properties and thermal stability from the *E coli* enzyme, but heavy labelling experiments prove that it is formed from polypeptide chain synthesized before infection Chrispeels *et al* believe that the phage-induced enzyme is a modified form of the host enzyme, possibly a dimer This conversion is specific (arginine, aspartic, leucine, phenylalanine, and serine-*t*-RNA synthetases of *E coli* are not modified by T_4 infection) and it is sensitive to chloramphenicol For these reasons, Chrispeels *et al* suggest as a working hypothesis that a new or altered valine *t*RNA produced by T_4 promotes the conversion of the host enzyme Whether the new enzyme plays an important part in the physiology of the phage is undecided, but since conversion of all the host enzyme occurs by about 15 to 20 minutes after infection, it is just possible that the conversion is involved in the regulation of early and late protein synthesis

Globin Metabolism in Thalassaemia

from our Medical Biochemistry Correspondent

THALASSAEMIA is a chronic haemolytic anaemia which is quite common in some parts of the world, particularly around the Mediterranean. The condition is due to an abnormal recessive gene which affects haemoglobin synthesis. Heterozygotes (with only one thalassaemia gene) usually show a mild chronic anaemia with a low haemoglobin concentration in the red cell. This condition, known as thalassaemia minor, can be more serious if the patient also has some abnormal haemoglobins. The homozygous condition known as thalassaemia major or Cooley's anaemia is a very serious disease which is usually fatal before the patient is adult.

The obvious explanation is that this is a serious defect of haemoglobin synthesis in thalassaemics, which have a substantial amount of foetal haemoglobin in their blood. It seemed probable that there was also a defect in the structure of the red cell stroma (the insoluble part of the red cell), for the cells have an abnormally short life-span. Recent work has shown that homozygous thalassaemics cannot synthesize the β-chain of haemoglobin, and that they also produce much more of the α-chain than is necessary for combination with the γ- and δ-chains synthesized. Labelling experiments have indicated that, in erythroid cells, the ratio of α-globin to γ-globin plus δ-globin was 3·0, but this ratio was never found in mature cells. The ratio there was 1·0, corresponding to the presence of normal haemoglobin A_2 and haemoglobin F.

It has now been shown (Bergollesi, Pontremoli, Manini and Conconi, *European J. Biochem.*, **3**, 364; 1968) that the excess of α-globin formed in reticulocytes from patients with thalassaemia major becomes associated with the stroma. Blood samples from nine patients with thalassaemia major and two normal controls (and bone marrow samples from two patients) were incubated in an amino-acid mixture containing tritium-labelled valine, leucine and lysine. In the control preparations, the activity of both cytoplasmic and stromal proteins increased for two to five hours and then remained constant, with very little label in the stromal proteins. In the patients' samples, the total cell label remained the same after five hours but the label was redistributed. The label in the cytoplasmic proteins increased rapidly for the first five hours and then decreased slowly, while the label in the stromal proteins increased slowly throughout the twenty-five hour incubation period.

Chromatographic separation of the cytoplasmic proteins showed that initially the ratio $\alpha/\gamma+\delta$ globins was 3·0, but as the tritium concentration in the cytoplasm decreased the ratio dropped to 1·0. Nearly all the labelled protein in the stroma was α-globin. The authors could find no α-globin in the stroma of mature red cells from thalassaemics, indicating that the α-globin must be further metabolized or firmly associated with the membrane in some way. It is tempting to assume that this reaction is the reason for the fragility of thalassaemic erythrocytes. Certainly further work on this interaction may indicate some of the factors affecting red cell stability.

Regulation of Lambda Genes

from a Temperate Bacteriophage Correspondent

It looks as though the temperate coliphage lambda is becoming another gold mine for molecular biologists. The phage has recently been attracting increasing attention, largely because it provides an experimental system for tackling problems of gene regulation at a higher level of complexity than those presented by the venerable lactose operon of *E. coli*. In the lactose operon, a single repressor protein prevents the expression of the three structural genes of the operon; similarly a lambda repressor prevents the expression of the entire phage genome, which has some thirty to fifty genes (see *Nature*, **217**, 509; 1968). Unlike the lactose genes, however, the genes of lambda are not all expressed co-ordinately after the repressor is removed, but instead they divide into several groups which differ in both the time and the level of expression during phage growth. Thus current interest in lambda centres on the mechanisms which control this ordered expression. Which lambda genes are controlled directly by the lambda repressor and which are controlled by other means during phage growth? A possible alternative to direct repression could involve regions of the phage genome which can be transcribed only by a phage specific RNA polymerase which might appear after the initial stages of infection.

Pereira da Silva and Jacob (*Virology*, **33**, 618; 1967) have just reported an investigation of the control of the expression of two genes, $C_{\rm II}$ and O, which function early in the growth cycle. $C_{\rm II}$ is involved in the establishment of the lysogenic (totally repressed) state and O is required for the vegetative replication of the phage DNA. Pereira da Silva and Jacob asked whether $C_{\rm II}$ and O are under direct repressor control or whether they are controlled by some other gene which is in turn under repressor control. Thomas (*J. Mol. Biol.*, **22**, 79; 1966) has proposed that the N gene, which maps adjacent to the lambda repressor gene and is itself controlled by the repressor, may control the expression of other lambda genes; he suggested that the expression of O requires the presence of the N gene product so that O is only controlled indirectly by the repressor through the mediation of the N protein. Pereira da Silva and Jacob's experiments, however, indicate that both O and $C_{\rm II}$ are directly controlled by the repressor and that they can be expressed in the absence of the N protein.

In their first experiment, they used lysogenic *E. coli* in which the prophage (the totally repressed phage chromosome) had a defective N gene; they irradiated these cells with ultraviolet light to inactivate the repressor and then showed that the $C_{\rm II}$ and O functions appeared in the cells. They detected the presence of $C_{\rm II}$ and O gene products by showing that they were supplied to superinfecting phages which lacked functional $C_{\rm II}$ and O genes. For both $C_{\rm II}$ and O the magnitude of the "rescue" effect increased if they delayed superinfection after irradiation, which implies that the $C_{\rm II}$ and O gene products accumulate after inactivation of the repressor.

In a second and similar experiment they used a cell lysogenic for the defective prophage *t*11 which, after induction, fails to produce a functional O gene product. These rescue experiments showed that the *t*11 genome also does not produce the $C_{\rm II}$ function; this finding lends further support to previous suggestions that $C_{\rm II}$ and O belong to a single operon.

Pereira da Silva and Jacob have thus shown that the $C_{\rm II}$ and O genes can be expressed in the absence of the N gene product, although their experiments do not eliminate the possibility that the N gene product enhances the expression of $C_{\rm II}$ and O during normal infection.

Memory and the Increase of Knowledge

by

J. Z. YOUNG

University College, London

In his Henry Tizard Memorial Lecture, delivered at Westminster School on February 29, 1968, Professor Young discussed the increase of knowledge and its storage in the brain.

THIS is an absurdly wide canvas I like to think that Henry Tizard would have approved of its objectives, though he might have been suspicious of its breadth I got to know him fairly well when he became president of Magdalen and I was his vice-president It was not altogether an easy task. His aims and ideas were on such a scale that I think he found it hard to be patient with our donnish concern with detailed studies, especially those not apparently directly relevant to current problems It is indeed difficult for the technologist, anxious to make immediate practical improvements, to know how to be patient with those who claim that theirs are the fundamental investigations, although they are not at present of any use. This is one of the problems that lies at the root of our worries about how to organize our search for knowledge and how to assess the results of research

I propose that we should handle it by considering that this is a problem about how the brain works This, of course, involves a whole host of questions about the nature of knowledge—whether it is a proper use of words to say that the brain acquires knowledge, if so, how does it do it, and many more questions In view of all that philosophers have said on these topics it is obvious that the scientist cannot really have the information to handle them But this knowledge about the brain, though it is so rudimentary, is growing very fast indeed. We have got to begin to get used to living with it.

A great deal is known by psychologists about the conditions under which memory operates, especially in man and the rat Almost nothing is known about its physical basis in the brain We do not even know what sort of thing or system the record or engram may be Before we can hope to find it, we must answer the very awkward question "What is the status of the concept of 'a record' ?". We are so familiar with the use of books, pictures, computer memories and other forms of physical records that we may find it hard to realize how complex they are They are all physical systems that in some sense have been made to represent or stand for other systems. What is meant by saying that one system represents another ? The words only have meaning of systems that have been devised by certain operations involving some conventional system of coding and addressing The process by which words of, say, the poet Dylan Thomas written on a page, represent for the reader a village in Wales is really most complex Similarly, a given point in the memory of a computer only represents part of, say, a bank overdraft if the numbers that pinpoint its position in a set of registers are activated at the right position in a sequence essentially of questions asked according to the programme with which the record in the memory was written The point in the computer memory in no other sense represents the bank balance, any more than the blot of ink of the L in Llaregyb represents the village of Laugharne in West Wales

Is the memory of the brain, like written or computer records, something highly addressed, with each point only of significance within the programme ? We do not know the answer to this and that is why I say we have almost no information about the physical nature of memory There is a strong presumption from what we do know about the organization of the nervous system that each unit for receiving and storing is specific for some particular feature that is relevant to the animal's life The method of encoding used is, in general, to put each item of information into a distinct channel. Thus in the cat the visual field is dissected in the sense that each cell of the primary visual cortex responds to an illuminated bar or contour, set at a particular angle. Other cells respond to more complex figures, but we do not know how the response to a whole scene, say, a saucer of milk or a dog, is computed by this multiplicity of channels There can be little doubt that within a few years we shall find out, and so perhaps gain great help with one of the most important technological problems of today—the design of machines for pattern recognition. Only when we have got far enough to know what the record is like shall we really be able to study how it becomes changed by learning But we can begin by dealing with units such as we know are present for the detection of particular features How could they be changed as a result of experience ?

The value of a memory to any system depends on the presence of more than one possibility of action in any given situation In the Pavlovian conditioned reflex the sound of a given note can produce either more saliva or less, or no change We have investigated the means by which such changes occur in octopuses, which, when a figure such as a horizontal rectangle is shown to them, can be taught either to come out to attack it or to retreat We can localize the part of the brain in which the record is written Moreover, octopuses can also learn to pull in a rough plastic ball and reject a smooth one, and the record ensuring this has been shown to be in a different part of the brain from the visual record

Remembering how the nervous system encodes, we postulate that for, say, horizontal rectangles there are special detector cells in the visual memory, and similarly there are detectors of roughness in the tactile memory

Each detector (or "classifying cell") must then be able initially to produce either the positive or negative action, whereas after training it produces only one or the other We have some evidence about how this limitation of possibilities occurs—perhaps through the secretion by certain small cells of substances that inhibit the unwanted channel Each classifying cell and its attendant cells thus constitute a unit of memory or mnemon, storing one bit of information Each mnemon is switched in one direction or the other by the action of nerve fibres signalling that a good taste or a trauma has occurred There is thus built up what may be called a model in the brain (following Kenneth Craik) This model indicates which of the possible actions that the animal can take is likely to be appropriate in the light of what has happened to it in the past

This concept of a model is quite helpful in a general way But the problems remain of finding out how it is used, how items of information are retrieved from it If it is made of units such as I have mentioned, how are they addressed, how is the action of millions of them combined to produce the behaviour of the whole organism ? We simply do not know the answers to these questions and it may be that it is wrong to try to isolate units of any sort Evidence is conflicting as to how far the records of particular events is localized Since Lashley it has been traditional to regard engrams as dispersed, because local lesions do not remove the record for individual items An attractive suggestion is that the record is like a hologram, in that it is dispersed and that activation of a part (in the appropriate way) evokes the whole There is, however, some evidence that there is more localization than Lashley supposed Thus electrical stimulation of one particular point on what Penfield calls the experiential cortex of the hemisphere of a patient under local anaesthesia may repeatedly elicit reports of a single scene Of course, these sites may not contain the actual record but be functionally connected with the neuronal record The nature of what is reported suggests that the report is itself part of the classifying system Reports are often of watching or hearing, seldom of acting, speaking or feeling

Perhaps what we have to think of is not so much how items are looked up in a great brain book as how the brain operates to solve each problem. We can even see a little of how the model grows in the developing brain, all the time serving the child's needs every day Children do not learn to speak by rote Finding the right words at 10–15,000 neuromuscular events/minute is not a matter of some demon darting about the brain looking them up in an addressed dictionary It is the result of the use of a speech-producing system, developed partly by maturation, partly by learning[1] First, the child's babblings acquire tonal contours, then single words are used as whole sentences, such as "daddy", with various intonations Then, strictly in sequence, come the use of two and three words, often one strong word, a so-called grammatical functor or "pivot", such as "it", "here" or "more", paired with a word from the growing vocabulary At each stage the speaker is making the response to input that is most likely to produce a satisfactory result in view of past experience The input finds the address by operating the system in the way that has been successful in the past

Such a system might be developed by the switching of mnemons There are said to be twelve places in the airway where antagonistic muscles produce speech Any classifying cell, say, one recording red light, may influence (indirectly) each of these points If it gives the "correct" response when red light occurs, the child will make a noise a bit more like "red" and will be rewarded, if only by approval, and the probability of this channel will be increased Once again we must be careful not to assume that what is being learned is a simple set of conditioned responses as Skinner once tried to demonstrate This position was subjected to a devastating criticism by Chomsky, but we need not be so frightened by his polemic as to give up the search for the changes that take place during the acquisition of speech It is not impossible that "at its origin grammar may well be acquired by mechanisms as naive as those of object-learning"[2] It is well to remember that object naming itself remains to some extent a flexible and creative process The category "a house" does not really refer simply to the class of all houses It is a word used in a certain way in speech—including, for example, house of God or House of Lords As Lenneberg[1] puts it, "Words are not the labels of concepts completed earlier and stored away, they are the labels of a categorization process or family of such processes"

Probably, however, the machinery of the brain contains systems the very nature of which we have not yet glimpsed. The timing devices and temporal sequences that are involved in nearly all behaviour patterns have been completely left out here, but may be essential features of the memory record Whatever the systems may be, we shall not find them unless we look And in order to look we must have words and hypotheses with which to describe and discuss our findings

This is the state of the study of one aspect of cerebral function today I have used it because, of course, it is the only subject that I know even a little about But perhaps it may serve as an example of what one field of research means today and of its significance for all of us Such studies of the brain have their immediate practical usefulness in education and medicine and surgery, by no means negligible But it would be grotesque to say that we only investigate them with these uses in mind The methods by which we think, remember and know are the background of all our activities A sound system with which to discuss them is likely to be productive of useful and satisfactory ways of proceeding in almost any other field of human action, certainly in all those that involve the brain

Of course, the achievement of such a system has been the aim of philosophers and scientists at least since Plato It seems to me that improvement of our system has been proceeding at an accelerating rate in recent years We may, of course, be deceived in this and certainly not all parts of our society show even a relatively secure confidence about the bases on which life can be lived I think this is a great pity and that we should actively proclaim that such insecurity need not continue.

The bases on which a useful system can be built become more secure every year, from the discoveries—for they are truly discoveries—of philosophy, linguistics and aesthetics, as well as those of science and technology How are we to ensure at the same time the further progress of discovery and the making widely available of its fruits both of detailed practice and of general theory ?

It has been in British academic life that many of the most important intellectual and scientific developments have begun I will not try to make a list for either philosophy or science, but I venture to think that in both fields our system has carried us far ahead of most countries, and many in those countries think so too. The combination of teaching and research that is made possible in our universities through the UGC system is in many ways the envy of the world We want to open it for large numbers of people and to give them a broader training, but let us be very careful that in doing so we do not give up its special virtues and relapse into mediocrity As some students put it to me the other day "We fear they want to turn the universities into battery farms for broiler technicians". Most people will agree that we need technologists, business administrators and many sorts of specialist, and that it is a large part of the function of universities as well as technical colleges to supply them Students themselves are anxious that their studies shall enable them to find their role (as they put it) in society Those who take degree courses that do not satisfy this role-seeking are the focus of unhappiness in universities all over the world[3] They complain that their courses do not prepare them to operate in the real world Interestingly enough, one group of complaints is against the breadth of education (as many as twelve subjects in one term in one course) Such complaints are common not only in North as well as South American universities but in those of Europe, which we are often asked to emulate by reducing our specialization This question should not be one of "taking sides" for or against specialization We should find out what the student needs in order to develop best at each stage At a given age, say, sixteen, he may begin to want to get down to details about some things and also to continue to widen his knowledge. Can this not be arranged ? In the university, can specialist teachers not arrange their subject matter so as to open wider horizons ? Certainly medical science provides a marvellous opportunity for a general education as well as a special one, if only we really insist that the student's growth requires both equally, and act accordingly They do not want to be part of battery farms What is the answer ? Do we want more different types and grades of education with segregation of the best ? The élite solution is appealing to many and is used in some countries, but I believe we should go the other way I have the greatest admiration for what our élite system has done for us in the past, and we can build on it Our best has been very good

But there is no reason why we should not make many more who are like them, provided we take real trouble to make sure that development is encouraged and not thwarted Let us get rid of the whole concept of a pool of ability, first and second class and so on Heredity has, of course, an influence on the brain, some studies would say "up to a half"—but half of what? No one really knows how to train the different sorts of brain or to estimate their productivity anyhow Let us find out before we condemn anyone as second-rate Let us say every day in every school and university that we are determined that our output shall be the very best Many "practical" people will say that this is unrealistic nonsense, that the less able will dilute and thwart the able I say in all seriousness and from thirty years of teaching that I do not believe it is necessarily so

Of course there are dangers in expansion Mediocrity is ready to creep in with the excuse that more must mean worse No one is likely to minimize the danger. But this is not, as some people seem to think, a law of nature. More can mean better, indeed, most concerns welcome more customers. We should be proud and glad that people want to go to universities Very sensible of them, I think But we must make sure that what we offer continues to be up to standard. This should be the main aim of all of us who want to improve university productivity I hope that the vice-chancellor of Lancaster and his colleagues who are investigating aspects of academic productivity for the Vice-Chancellors Committee will put the problem of standards at the very front of their studies and statements. We know how hard it is to measure amounts of knowledge—absurd to try, most people will say But yet we all admire some academics more than others, so we must be applying some sort of measure. At any rate we must give special attention to finding ways to ensure the maintenance of standards, however difficult it may be We should make this our first priority. Unless we do so, education becomes a fraud Counting heads is a poor method of measurement if you neglect to consider what you are putting into them

The majority of people will reach astonishingly high standards of intellectual interest and understanding, provided they are challenged with the highest by meeting not complex dogma but problems to be faced in a manner they can understand We have hardly begun the detailed study of how to help the development of the brain as a problem-solving device. The child learns to speak by experimenting with additions to his grammar and vocabulary as his needs expand The six year old nowadays learns set theory by doing experiments with numerods The university student will learn to understand and operate with complex concepts if he is taught by someone who is himself wrestling to improve those concepts He is much less likely to do so if he is presented with them as material to be learned dogmatically

How does all this affect the problems with which we started as to how knowledge increases and how the increase may be assessed? We have seen that studies of the brain suggest that it is not a classified record like a book but a calculating machine that gives useful answers when it is operated by the demands of experience. The specification is terribly vague and could be greatly improved even now, but it is interesting to compare it with a definition of a modern view of epistemology "Belief, like knowledge, is not an act . . . it is a disposition or tendency to act (including to speak) in certain ways under certain conditions"[4] Looked at from our point of view, the knowledge of an individual is the organization incorporated in the model in his brain. The details of this model, of course, are built largely by the influence of other people on him, but what then is new knowledge? It can only be the acquisition of new tendencies or dispositions to act and these can only be acquired by experience and trial and error and practice. When any student acquires "new dispositions" there is an increase of knowledge, provided, of course, that these are "correct", in the sense of enabling him to operate more usefully (though we might have further trouble defining that word). I believe that all learning proceeds best when it is a form of research and that all research is a form of learning. The activities cannot and should not be separated at any stage, from the work of the youngest child to that of the oldest don. No method has been devised by which the increase in knowledge from teaching and research can be measured. Yet schools and especially universities are places whose function is the increase of knowledge, the improvement of "dispositions to act" so that more correct and useful decisions shall be reached And in case anyone should condemn this as utilitarian, I will agree with them that increase of knowledge is good for its own sake There is perhaps nothing more beautiful or satisfying than to learn, to know and above all to find out new facts and pass on new ways of thinking to others. Our university system will continue to be healthy in spite of expansion so long as those who are responsible for sponsoring academic productivity and assessing its output continue to emphasize loudly and repeatedly that the aim of the system is the increase of knowledge, jointly by teaching and research.

Optical Identification of the First Neutron Star?

by
M. RYLE
JUDY A. BAILEY
Mullard Radio Astronomy Observatory,
Cavendish Laboratory,
Cambridge

A more precise position for one of the rapidly pulsating radio sources has been found. This has suggested that the source is associated with an eighteenth magnitude blue star

In a recent communication from this observatory, Hewish *et al*[1] have described the discovery of a new class of celestial radio source of very small physical size which emits short pulses of radiation with an extremely constant repetition frequency It was suggested that the radio signals might be associated with the gravitational vibration of a white dwarf or neutron star which could excite repetitive shock disturbances in the stellar atmosphere.

The discovery and detailed study of a neutron star would prove of the greatest importance, both in relation to the properties of super-dense matter and in the mechanism occurring in the gravitational collapse of a star. The possibility that the object discovered by Hewish and his collaborators is indeed a neutron star is thus of great interest, and further investigations by all available methods and over the widest possible range of wavelengths are now required.

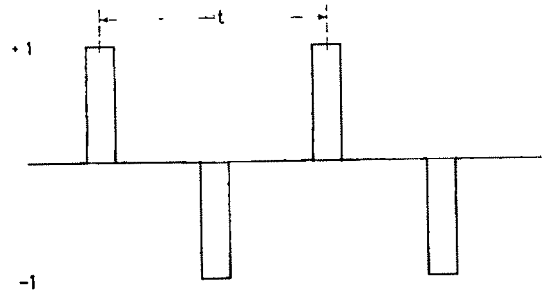

Fig. 1 The time sequence of the commutator

The original observations at 81.5 MHz allowed the position to be determined with an accuracy $\Delta\alpha = \pm 3^s$ $\Delta\delta = \pm 30'$. The measurement of the variation of the received repetition frequency caused by the Earth's orbital motion over a period of a month gave an independent value of the declination which was in good agreement with that obtained from the directivity of the aerial system, but the errors were still too large to allow the recognition of any faint optical object which might be associated with the source.

Observations have recently been made at higher frequencies of 408 and 1,407 MHz using the one-mile radio telescope in order (*a*) to establish a more precise position and (*b*) to obtain information on the radio spectrum of the pulses. The 81.5 MHz observations have shown that the source is very weak with a flux density in the pulse which varies both from minute to minute and over the months of observation. During most periods the power received from each pulse is $\sim 0.5\times10^{-26}$ J m^{-2} Hz^{-1}, so that the mean flux density $S_{81.5} \simeq 0.35\times10^{-26}$ W m^{-2} Hz^{-1}. Special recording methods have therefore been used with the one-mile telescope, both to allow the measurement of the small mean flux density and to distinguish the source from the more powerful normal sources which are likely to be found in its neighbourhood. The method makes use of a filtering process based on the characteristic recurrence frequency of the signal both to reject the response due to constant sources and to permit the use of a long effective integration time. In order to avoid the necessity for recording at a high sampling rate, which would be necessary if the filtering were carried out entirely in the computer, the reduction was performed in two stages.

(*a*) The output of the receiver was switched, using commutating relays, in the time sequence shown in Fig. 1, where the widths of the positive and negative gates are each one-eighth of the total period t, which was made close to the known period of the pulses observed at 81.5 MHz. The commutator was driven from the sidereal crystal clock.

If the commutator is synchronized so that the incoming pulses fall in one or other of the gates, the output from the relays contains a d.c. component proportional to the mean flux density, and integration can be used to increase the signal to noise ratio; the noise level is also reduced relative to that of an unswitched receiver output, while all constant sources produce alternating outputs at the switching frequency which will be rejected by the low-pass filter.

By choosing the period t to differ slightly from that of the incoming pulses (t_0), the output from the filter will alternate with a waveform similar to that shown in Fig. 1, but with a greatly increased period T given by

$$\frac{1}{T} = \frac{1}{t} - \frac{1}{t_0}$$

In practice a value of $t = 1.344328$ sidereal seconds (equal to 1.340654 solar seconds) was used, giving a value of $T \sim 520$ s and the signal from the commutator was smoothed with a time constant of 10 s and sampled at intervals of 20 s. This signal was digitized and recorded on punched paper tape in the manner normally used with the one-mile telescope[2].

(*b*) The reduction in the computer followed that normally employed in the determination of the position of a source[3] except that a convolution operation was first carried out using a function similar to that shown in Fig. 1 but having a periodicity close to T. This operation was necessary because the phase of the incoming pulses and hence of the signal of period T is unknown. The convolution, which corresponded to integration over a period of 30^m, was carried out with displacements of $T/16$. The results were presented as a series of 12^h plots giving the amplitude and radio frequency phase relative to that of a source at an assumed position, the residual variation of the phase then allowed the difference between the true and assumed positions of the source to be determined.

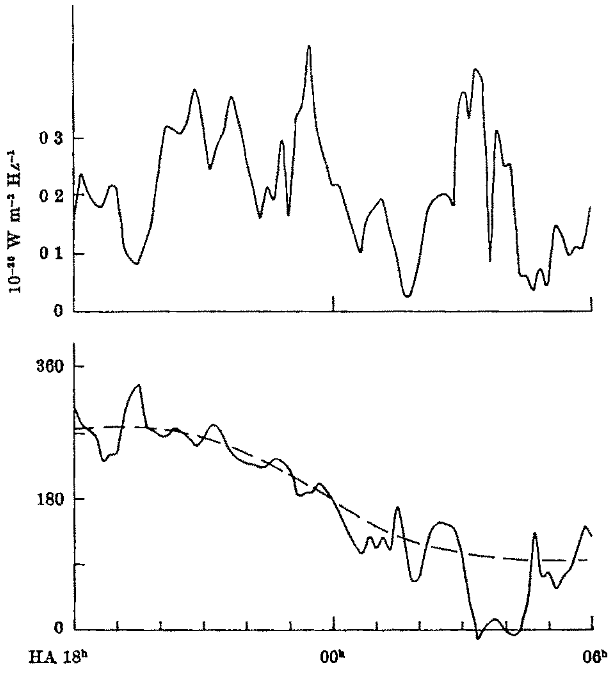

Fig. 2 Record obtained at 408 MHz using an aerial spacing of 900 λ on January 23, 1968. The top trace shows the variation of flux density during the 12^h observing period. The lower trace shows the variation of the radio-frequency phase relative to that of a source at an assumed position close to the actual position. The dashed curve shows the variation of phase computed for a source at the final adopted position.

If the values adopted for t and T are sufficiently accurate, the signals will continue, with particular displacements of the convolving function, for the whole 12^h period. If the adopted value of T is incorrect, the signal on any one output will disappear during the run and reappear with another displacement.

One of the output records for the observations of January 23, 1968, with a value of $T = 532.773$ sidereal seconds, which is very close to the optimum value, is shown in Fig. 2, the assumed position was about 4′ arc south of the true position, and the dashed line shows the variation of radio-frequency phase appropriate to the final adopted

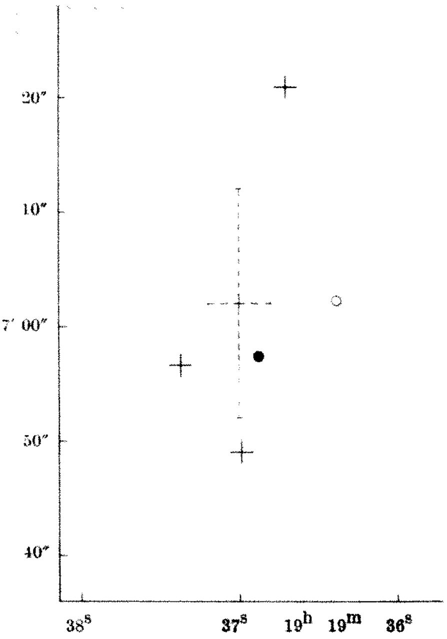

Fig. 3. The positions of the source obtained from successive observations at 408 MHz are indicated by the crosses; the dashed cross represents the mean position and error. The 18^m blue star is indicated by the disk and the faint red object by the open circle.

position. From this record and from others reduced with a slightly different value of T (525·0 sidereal seconds) the periodicity of the incoming pulses was derived; when corrected for the orbital velocity of the Earth, a value of $P_0 = 1{\cdot}337283$ solar seconds was obtained in good agreement with the more accurate value of 1·3372795 derived by Hewish *et al.*

The small flux density and the variability of the source make it difficult to obtain an accurate measurement of its position, but the results from three 12^h observations at 408 MHz are presented in Fig. 3. The mean position is

$$\alpha(1950{\cdot}0) = 19^h\ 19^m\ 37^{s}{\cdot}0 \pm 0^{s}{\cdot}2$$

$$\delta(1950{\cdot}0) = 21^\circ\ \ 47'\ \ 02'' \pm 10''$$

A search has been made using an overlay technique[4] to locate the source on the prints of the Palomar Sky Survey, and enlargements of both red and blue prints are shown in Fig. 4. These photographs show that close to the position of the radio source there is an 18^m blue star, with a fainter red object some 8″ arc north-west. More precise positions of these objects were therefore obtained by measuring the distances from a number of *AGK*2 stars. The results support the association of the radio source with the blue star the co-ordinates of which are

$$\alpha(950{\cdot}0) = 19^h\ 19^m\ 36^{s}{\cdot}88 \pm 0^{s}{\cdot}1$$

$$\delta(1950{\cdot}0) = 21^\circ\ \ 46'\ \ 57''.4\ \pm 1''{\cdot}5$$

Although this position corresponds to the epoch of the Sky Survey (1950·5) the interpretation of the observed dispersion of the 81·5 MHz signals in terms of the effect of the interstellar medium suggests a distance of 50–100 pc so that any proper motion is unlikely to exceed 3″ arc.

The discrepancy in the measured position of only 5″ arc suggests strongly that this blue star should be associated with the radio source and further optical observations are now needed. It is possible that measurements of its spectrum and proper motion will provide further evidence to relate it to the radio source. Conclusive evidence would, however, be provided if it were found to exhibit fluctuations of light intensity having the same period as that of the radio emission; the radial oscillations of the star may excite shock fronts in the atmosphere which are responsible for both optical and radio emission. It is possible that electromagnetically accelerated electrons might account for the very high optical surface brightness required without the intense X-ray emission which would accompany thermal excitation; in this case the optical emission might well exhibit the same pulsed characteristics.

Observations at 1,407 MHz, while not having sufficient signal to noise to provide an improved position, have given some evidence on the flux density, and the results have been combined with those at 81·5 and 408 MHz to provide information on the radio spectrum. The spectrum of a given pulse would be of particular interest, and could be determined in principle by correcting for the different times of travel (amounting to some 8 s) derived from the observed dispersion. Such a measurement is not, how-

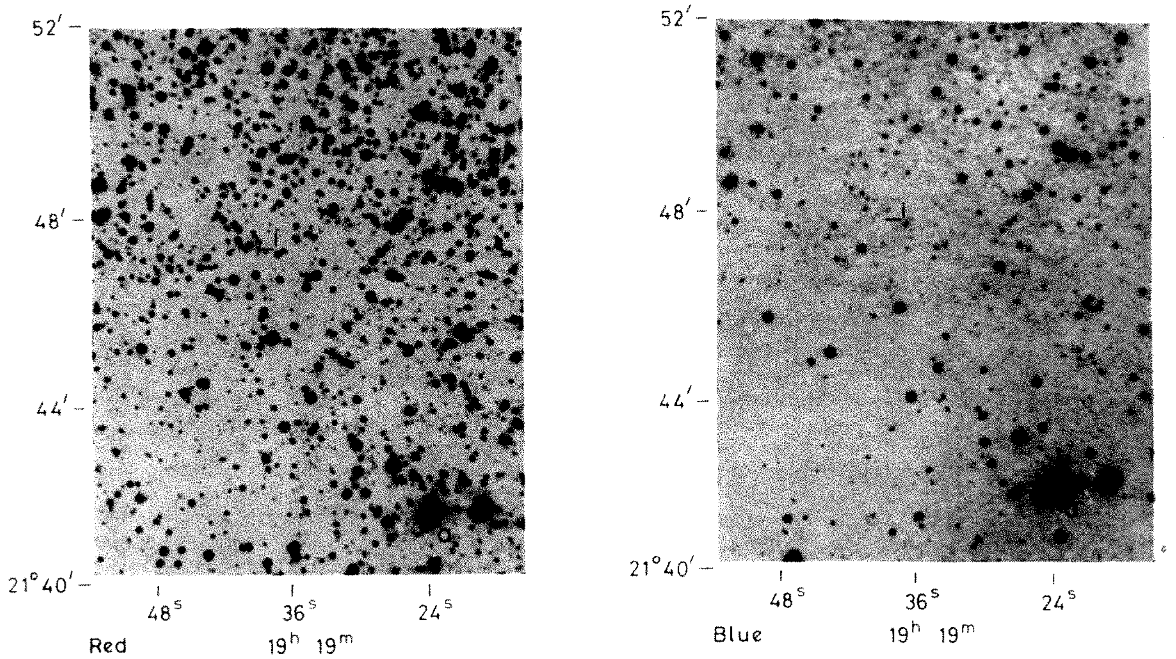

Fig. 4. Enlargements of the red and blue prints of the Palomar Sky Survey showing the radio position. The bright star (*a*) in the south-west of the area is *AGK*2 + 21°. 1963. (© 1957 National Geographic Society—Palomar Observatory Sky Survey.)

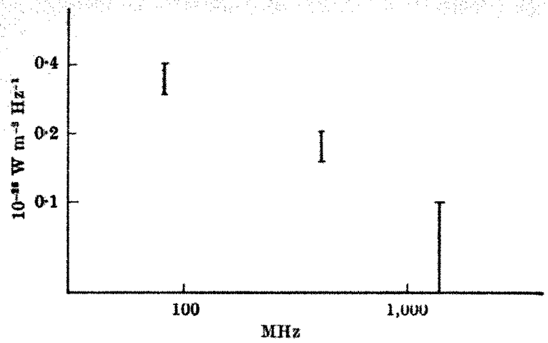

Fig. 5. The mean flux density of the source at the three observing frequencies.

ever, practicable both because of the poor signal to noise ratio in the present observations, and because of the effect of interplanetary scintillation[5] at 81·5 MHz. Instead a mean spectrum has been derived by comparing the average flux densities over the 12^h observing periods with the average flux density observed at 81·5 MHz over a comparable total time during the period December 1967 to February 1968.

The results are shown in Fig. 5. The very high surface brightness (which is probably some 10^5 times greater even than those occurring in QSS) and the absence of a cut-off at low frequencies indicate that the emission cannot be attributed to the synchrotron mechanism[6]; as with the emission from sunspots and from the compact low frequency source in the Crab Nebula[7], it is more likely that it is due to coherent electron motion in plasma oscillations.

Although this new class of object probably only represents about 1 in 5,000 of the total source population at a given flux density, the remarkable character of their emission makes it possible to distinguish them for a more detailed examination of their characteristics.

We thank Drs P. F. Scott and D. M. A. Wilson for helping to assemble the special recording system, and Mr C. D. Mackay and Dr D. Wills for locating the position of the source on the Sky Survey prints, and for making accurate measurements of the position of the blue star.

Received March 4, 1968.

Pulsating Radio Source at $\alpha = 19^h 19^m$, $\delta = +22^\circ$

Signals from one of the rapidly pulsating radio sources have been recorded on three frequencies using the mark I radio telescope at the Nuffield Radio Astronomy Laboratories. The size of the source, deduced from the form of the signals, again seems consistent with an origin in a white dwarf or neutron star.

At the time of publication of the remarkable discovery by a group of Cambridge radio astronomers[1] of the pulsating radio source at $\alpha = 19^h 19^m 39^s \pm 3^s$, $\delta = +22^\circ \pm 30'$ (1950), the mark I radio telescope was equipped for reception at frequencies of 151, 240 and 408 MHz. The receivers were intended for studies of flare stars and interplanetary scintillations, and an Argus 400 digital computer was in use for the on-line analysis of the receiver outputs. It was therefore decided to search for radio pulses from this source at these receiver frequencies, which were above that of the original observation at 81 MHz. Radio pulses were found at all three frequencies, the first observation being on February 24, 1968. The position of the source agreed well with the original observations; the declination was measured as 21° 40′ ± 7′ (1950).

The method of analysis was to obtain an average pulse shape at each frequency by superposing receiver outputs over a number of cycles of the pulse repetition period of 1.33724 s. Each cycle was divided into shorter intervals, originally of 20 ms duration. When the position of the pulse within the period became clear, the interval was reduced progressively and the time scale was expanded, until for some experiments only 64 ms of each period were examined, with a time resolution of 1 ms. Most of the observations were made using three receiver channels simultaneously, recording the average in 32 intervals of 10 ms on each channel. Integration of pulses by this technique usually lasted for periods of 2 min.

Observations were then directed toward measurements of pulse shape at the three frequencies, and to the measurement of the relative times of arrival. The source was also followed for some hours on several days to record the variations of pulse amplitude which occurred on all three frequencies.

Shape of the Pulses

Fig. 1 shows mean pulse shapes at 408 MHz. Individual pulses at 408 MHz have also been recorded directly on a fast ultraviolet recorder, using a receiver time constant of 1 ms. These are shown in Fig. 2.

The average pulse shows a very sharp rise on all frequencies. This steep rise may have been appreciably slowed in these measurements by the differential time of arrival across the receiver bandwidth, which was 1 MHz. At 151 MHz this effect would stretch the pulse by 22 ms, at 240 MHz by 7 ms, and at 408 MHz by 1·5 ms. It appears that the initial rise may in fact occur within 2 ms at 408 MHz, and there is no evidence that the rise is slower at the lower frequencies.

The pulse lasts for about 35 ms on all three frequencies. This duration is consistent with the measurements on

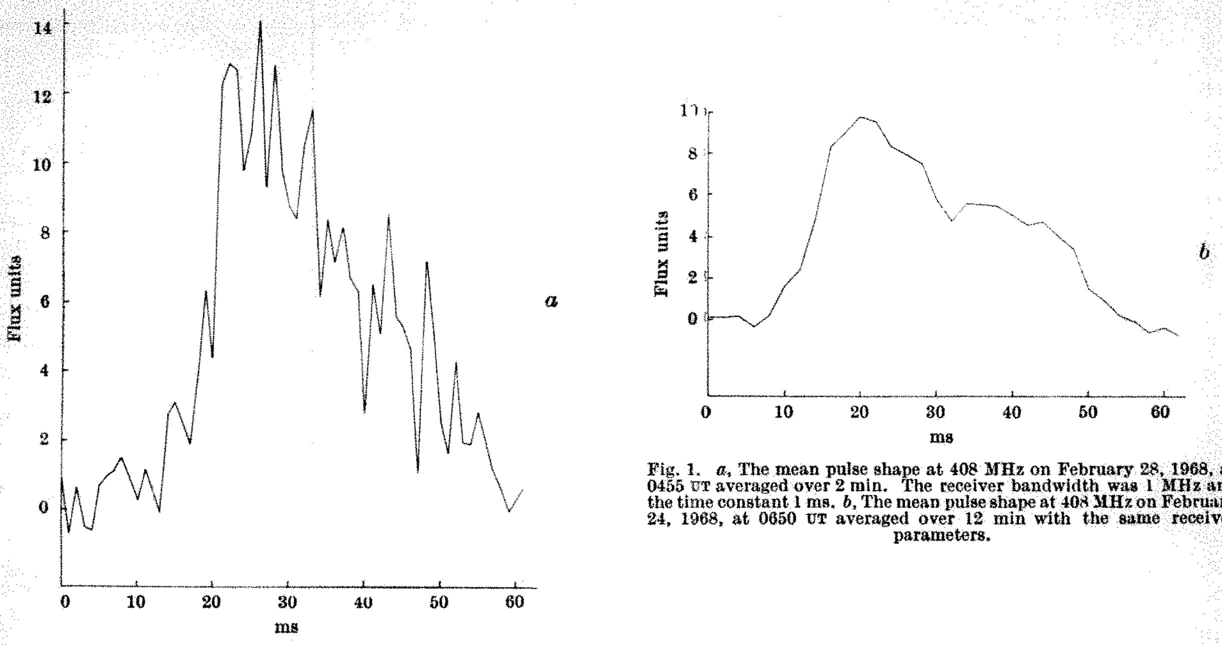

Fig. 1. *a*, The mean pulse shape at 408 MHz on February 28, 1968, at 0455 UT averaged over 2 min. The receiver bandwidth was 1 MHz and the time constant 1 ms. *b*, The mean pulse shape at 408 MHz on February 24, 1968, at 0650 UT averaged over 12 min with the same receiver parameters.

81 MHz, where a delay technique was used to measure the autocorrelation function of the pulse envelope. The autocorrelation function was originally interpreted in terms of a gaussian shaped pulse with width 17 ms. The roughly triangular pulse shape now observed gives a similar width of autocorrelation function, and we conclude that the duration of the pulse is in fact the same at all frequencies so far observed. There is no sign of any impulsive emission outside the normal duration of the pulse.

The measured pulse shape is variable in detail, both between successive pulses, as seen in Fig. 2, and also on averaged pulse shapes. Fluctuations are observed on

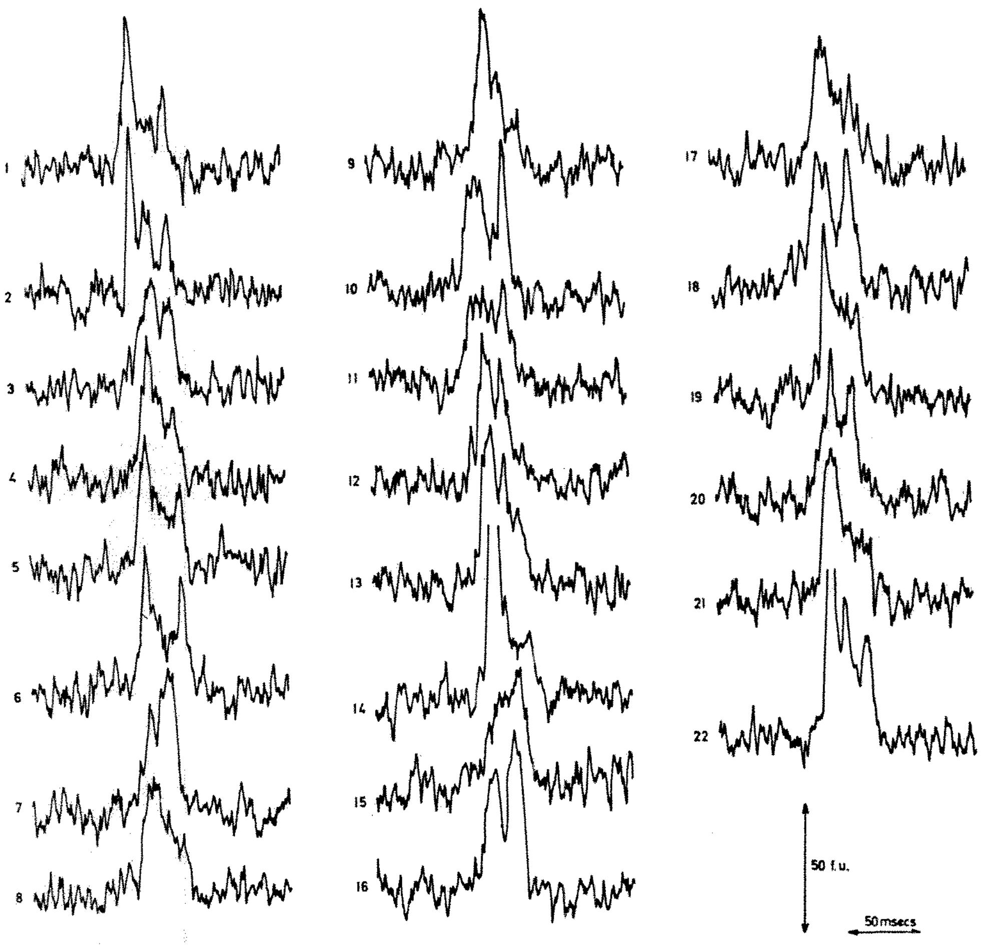

Fig. 2. A series of pulses recorded directly at 408 MHz (bandwidth 4 MHz, time constant 1 ms) on February 29, 1968.

time scales down to 1 ms, the limit of time resolution. The time of onset within the period of 1,337 ms is, however, stable within about 5 ms, a remarkably small limit considering the wide variability of pulse amplitude which is observed on all frequencies.

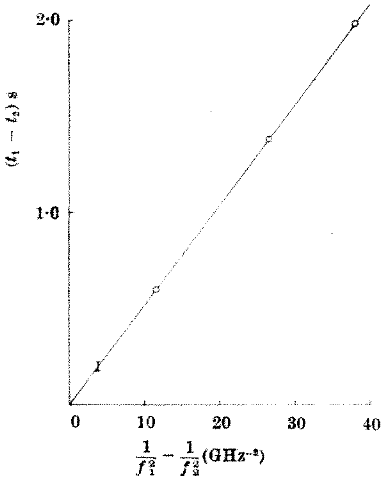

Fig. 3. Dispersion in arrival time of pulses at 151, 240 and 408 MHz. The errors are too small to show. An additional point at 0·2 s delay is obtained from the Cambridge observation at 80·5 and 81·5 MHz.

Pulse Delay

Differences in arrival times of the sharp leading edge could be determined with an accuracy of about 5 ms. We therefore tested the suggestion that the dispersion in arrival time on the three frequencies was due to group delay in the propagation path through ionized interstellar gas. If the pulse at frequency f_1 was emitted at time T_1 and observed at time t_1, then

$$t_1 - T_1 = A + \frac{B_2}{f_1^2}$$

where A is the free-space travel time and B is the dispersion constant. Fig. 3 shows the difference $t_1 - t_2$ plotted against $\left(\frac{1}{f_1^2} - \frac{1}{f_2^2}\right)$. The points lie on a straight line whose intercept with the vertical axis is 0 ± 5 ms, showing that the differences in emission times over the frequency band are either very small or that they themselves follow a similar dispersion law. We suggest that the emission in fact takes place nearly simultaneously on all frequencies.

The observed dispersion constant B yields a measure of the integrated electron density in the line of sight equal to $12{\cdot}55 \pm 0{\cdot}06$ pc cm^{-3}.

Pulse Amplitude

It is difficult to determine the spectrum of the radio emission, because the amplitudes on all three frequencies are variable, and the variations are not obviously related between the three frequencies. On all three frequencies the flux density during the pulse was usually between 2 and 20×10^{-26} W m^{-2} Hz^{-1}, measured as the peak of the mean profile averaged over 2 min. The direct recordings of single pulses on 408 MHz show short peaks of over 100×10^{-26} W m^{-2} Hz^{-1}.

Fig. 4 shows the variation of pulse amplitude on 408 MHz for a period of 6 h on February 28, 1968. Variations occur on a wide range of time scales. The most prominent feature is a rapid rise by a factor of more than 10, which may persist for 10 min or more and recur after 1–2 h. Variations over a period of 10 s seem to be less than those reported at 81 MHz. No truly periodic variability has been observed.

A receiver at 2,695 MHz on the mark II telescope was also used, and it soon appeared that the flux density of the pulses was much lower at this high frequency. Observations for a period of 3·25 h (1316–1631 UT on February 29, 1968) would have detected a flux density during the pulse, averaged over any one minute, of $0{\cdot}1 \times 10^{-26}$ W m^{-2} Hz^{-1}, but nothing was detected on this frequency.

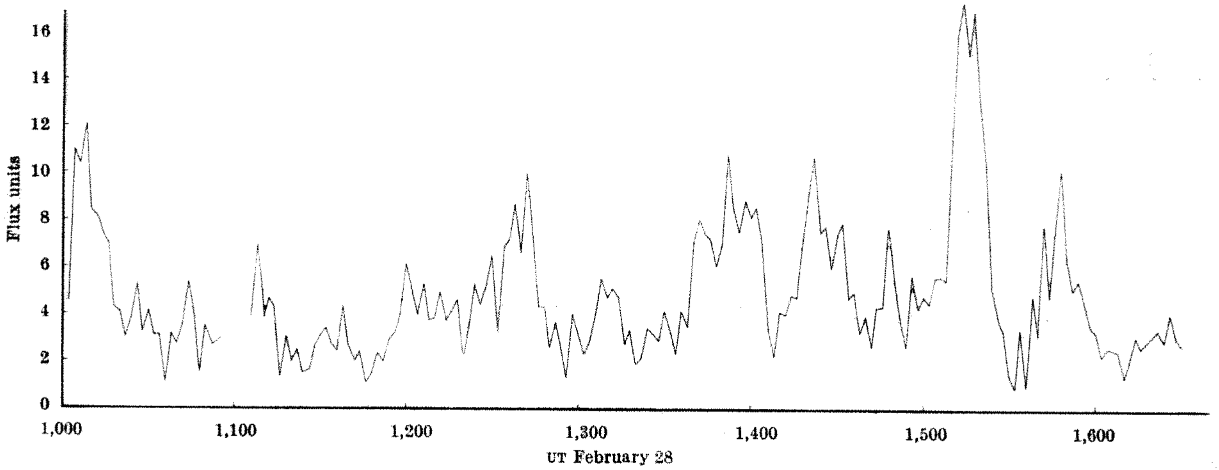

Fig. 4. The variation of pulse amplitude at 408 MHz, averaged over 2 min, for an observing period of 6 h on February 28, 1968.

Nature of the Source

The observation of the nearly simultaneous onset of emission of the pulses on three widely spaced frequencies suggests that the pulses on the various frequencies originate in regions which are separated by less than 1,000 km. Again, the total duration of the pulse, which is the same at all four frequencies, indicates that all sources of the emission lie within a distance of 10,000 km. These distances are consistent with an origin in the very condensed corona of a collapsed star, such as a white dwarf or neutron star, as suggested in ref. 1.

If the origin of the radiation is at a distance of 60 pc, as was suggested to explain the dispersion of arrival time, the simultaneous generation of pulses over a wide bandwidth implies a radiated pulse power of about 10^{21} W and a pulse energy of 2×10^{19} J. If the source is a star with radius 10,000 km, the power flux at the surface is about 3×10^{5} W m^{-2}, corresponding to a field strength of 10^{4} V m^{-1}. These values would, of course, be even larger for a smaller star.

Received March 2, 1968.

INSTRUMENTATION

Development of High Energy Neutrino Experiments at CERN

by

C. A. RAMM

CERN, Geneva,
Switzerland

Equipment at present under construction and the new developments foreseen will increase neutrino event rates by large factors. Neutrino experiments will become a major field of high energy physics, leading to a further understanding of the interactions of these important particles.

RECENTLY the interactions of high energy neutrinos with free protons were photographed for the first time. This is the latest of a series of experiments which started some 40 yr ago in the Cavendish group when Ellis and Wooster were so perplexed by an apparent violation of the Law of Conservation of Energy that they devised an apparatus to determine whether a new form of neutral radiation accompanied the electrons from β-emitters. Their experiment was at least 10^{20} times too insensitive; it was not until a quarter of a century later, after the invention of the atomic reactor and much more perceptive detectors, that the existence of free antineutrinos was confirmed experimentally by Cowan and Reines and their co-workers. Still another decade elapsed before the first interaction of high energy neutrinos was observed.

There are probably more neutrinos than there are atoms in the universe; nevertheless, Pauli, who first postulated the existence of the neutrino to conserve momentum, energy and angular momentum in β-decay, wagered they would never be detected. The cross-sections for neutrino interactions, which are governed entirely by the weak force, must have seemed to him impossibly small for laboratory experiments. Bethe and Peierls first estimated that the capture of low energy antineutrinos by protons had a cross-section of about 10^{-43} cm². Lee and Yang showed that the cross-section for such a process of inverse beta decay increases with energy and reaches a maximum of about 10^{-38} cm², at about 1 GeV for neutrinos ($\nu_e + n \rightarrow e^- + p$), and at a somewhat higher energy for antineutrinos ($\bar{\nu}_e + p \rightarrow e^+ + n$). The weak interaction rates are so low that it is very difficult to invent experiments to observe them for particles which also exhibit strong and electromagnetic interactions. Before 1961 all experiments with the weak force had been concerned with the spontaneous decay of nuclei or particles, or the capture of reactor antineutrinos by protons. Although significant discoveries and deductions were made, including the violation of parity in weak decays of nuclei, and the two-neutrino hypothesis, the understanding of the weak phenomena was faced with a handicap analogous to that which would exist if the strong force could only be studied in low energy nuclear interactions.

The simplest theoretical approach to the weak process—and still the most successful—is the concept of the interaction of four leptons at a single point in space and time. To resolve certain impossible consequences of the theory, such as the ever increasing interaction cross-sections with energy, the concept of the intermediate boson was developed as a means of giving such an interaction a spatial distribution. Experimentalists saw this situation as an additional compulsion to study directly weak interactions at high energies to try to understand the fundamental phenomena; the only evident means was by the direct observation of high energy neutrino interactions.

Many unstable nuclei and particles have some mode of decay which produces neutrinos. The most energetic nuclear processes produce $\bar{\nu}_e$ of less than 15 MeV; pions, kaons and muons at rest yield higher energy neutrinos: $\pi^+ \rightarrow \mu^+ + \nu_\mu + 34$ MeV, $K^+ \rightarrow \mu^+ + \nu_\mu + 388$ MeV, $\mu^+ \rightarrow e^+ + \nu_e + \bar{\nu}_\mu + 105$ MeV. Both pions and kaons also produce ν_e, but only kaons ($K^+ \rightarrow e^+ + \pi^0 + \nu_e$, $K^0 \rightarrow e^+ + \pi^- + \nu_e$) have useful branching ratios. The cosmic neutrino flux comes from such origins, and others too, particularly ν_e from the formation of the elements in the Sun and other stars. Although these fluxes have a large total intensity—more than 10^{14} m^{-2} s^{-1} from the Sun—they are diffuse and the interaction rates are small so that no interaction of low energy neutrinos and only a few tens of interactions of high energy cosmic neutrinos have so far been detected. Nevertheless, as always, cosmic ray experiments have access to the highest possible energies.

Laboratory experiments have become feasible with ν_μ and $\bar{\nu}_\mu$ derived from the secondary beams available from the most powerful proton accelerators, the 31 GeV AGS at Brookhaven, the 25 GeV PS at CERN and the 12·5 GeV ZGS at Argonne. In the first high energy experiment[1] in 1962, the Brookhaven–Columbia group, with an allocation of about 1,000 h of the AGS, succeeded in recording 51 muons generated by muon neutrinos in 10 tons of spark chambers. This mixed beam of ν_μ and

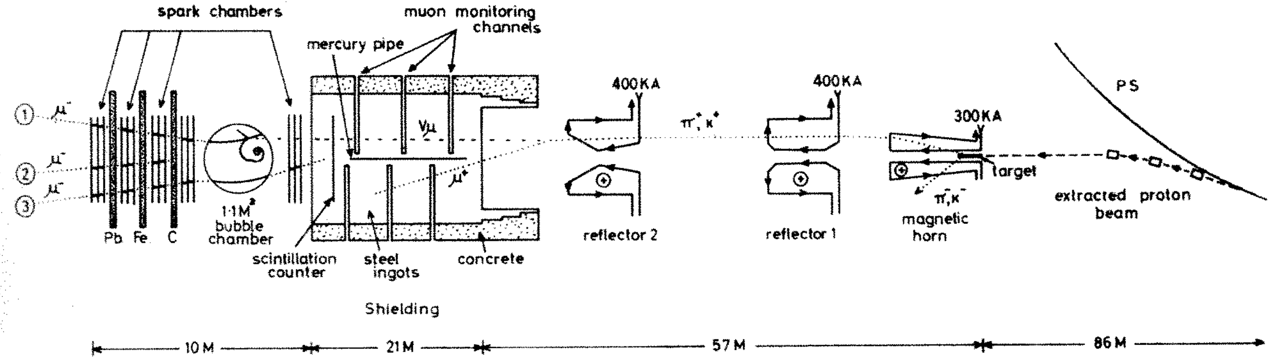

Fig. 1. CERN—new neutrino facility. The disposition of the various elements is shown schematically, including the 6,000 tons of steel shielding. Three types of ν_μ events are shown; (1) is an event produced in the bubble chamber, (2) is an event in a carbon plate in the spark chamber installation and (3) is an event in which the muon produced in a part of the shielding traverses the bubble chamber, where its sign and momentum can be distinguished.

$\bar{\nu}_\mu$ was derived at 7·5° from a fraction of the pions and kaons produced in an internal target. Due to the construction of the accelerator, most of the neutrino parents, which are concentrated near the forward direction, were lost. After a free flight of 21 m all particles except neutrinos were absorbed in a massive steel shielding in front of the detectors, otherwise the very rare neutrino interactions could never have been detected against the overwhelming background of accompanying particles. Almost no evidence of interactions producing an electron was seen and so it was concluded that interactions of ν_μ and ν_μ produce muons and not electrons. Thus the two-neutrino hypothesis that ν_μ and $\bar{\nu}_\mu$ are different particles from ν_e and $\bar{\nu}_e$ was confirmed. It was evident also that much higher neutrino interaction rates were essential for further work in this field.

In the subsequent experiments at CERN[2,3] and later at Brookhaven[4] and Argonne[5], two fundamental technical advances were made; the proton beam was extracted[6] from the accelerators, so that forward going neutrino parents could also be used, and focusing devices were developed to direct the parents towards the detectors so that the neutrinos had the highest probability of traversing the detectors. Neutrino parents from various parts of the target in which they are produced by the protons have a broad distribution in energy and direction. By means of computer explorations, various toroidal magnetic lenses have been invented for guiding such parents; the first such device, called a "magnetic horn", was developed at CERN[7] and also used at Argonne; it is shown in Fig. 2a and b. While the proton beam bombards the target, the two conical coaxial conductors carry a current

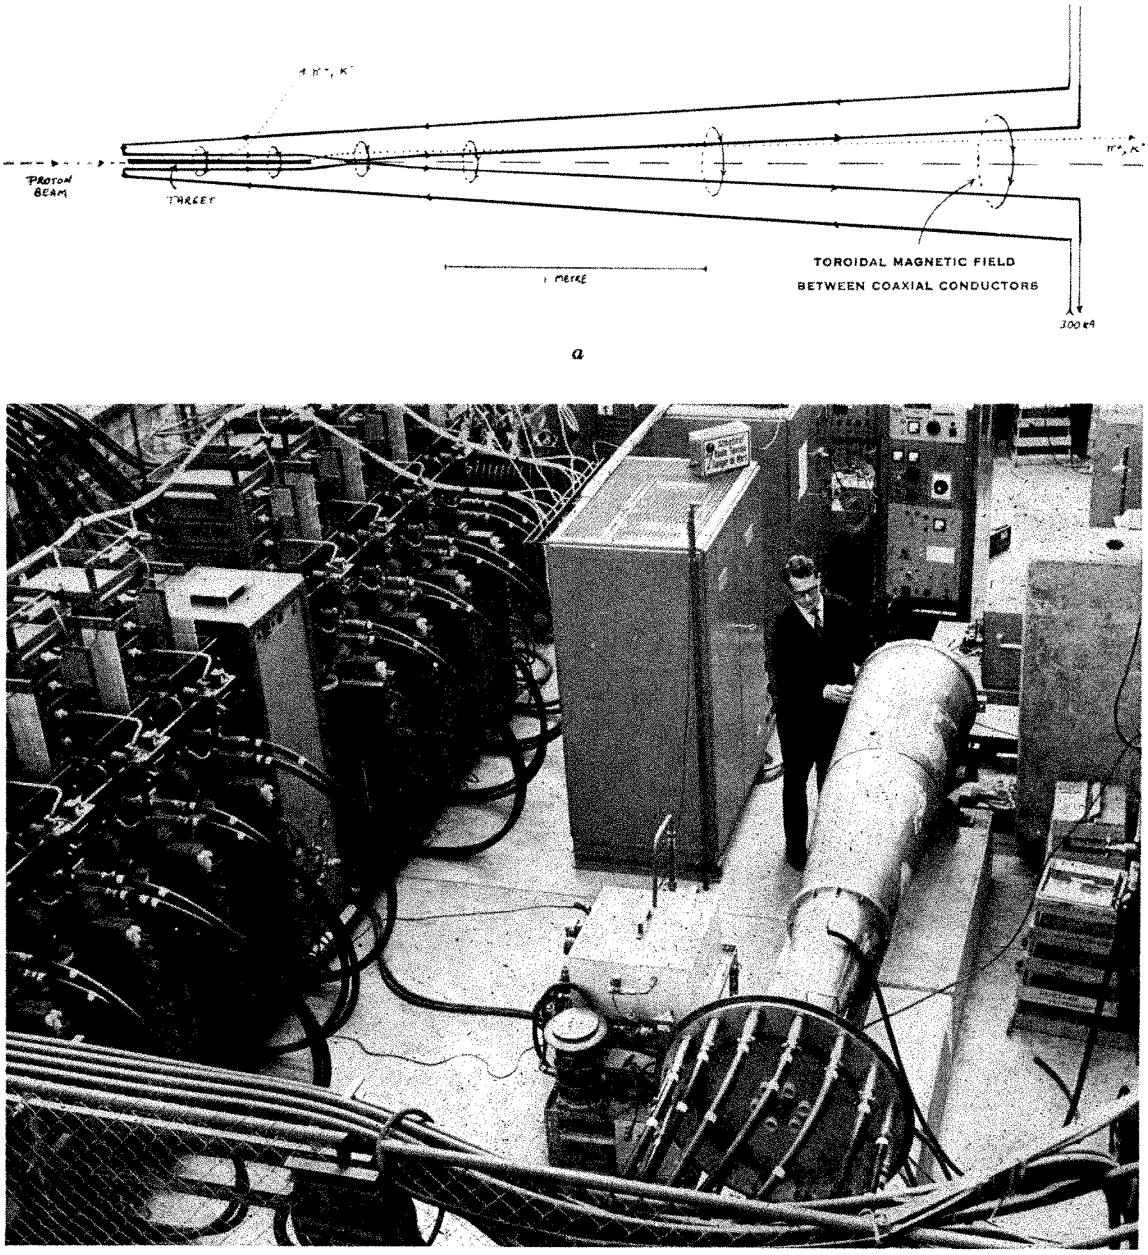

Fig. 2. *a*, Principle of the magnetic horn. The current pulse in the two axial conical conductors produces an azimuthal magnetic field between them which deflects charged particles towards or away from the axis according to their sign. The outline is the latest version of the magnetic horn. *b*, Testing the first magnetic horn. The condenser banks and ignition switches are on the left, the multiple coaxial cables which carry a total current of 300 kA are in the foreground. (CERN Photo 317-1-63.)

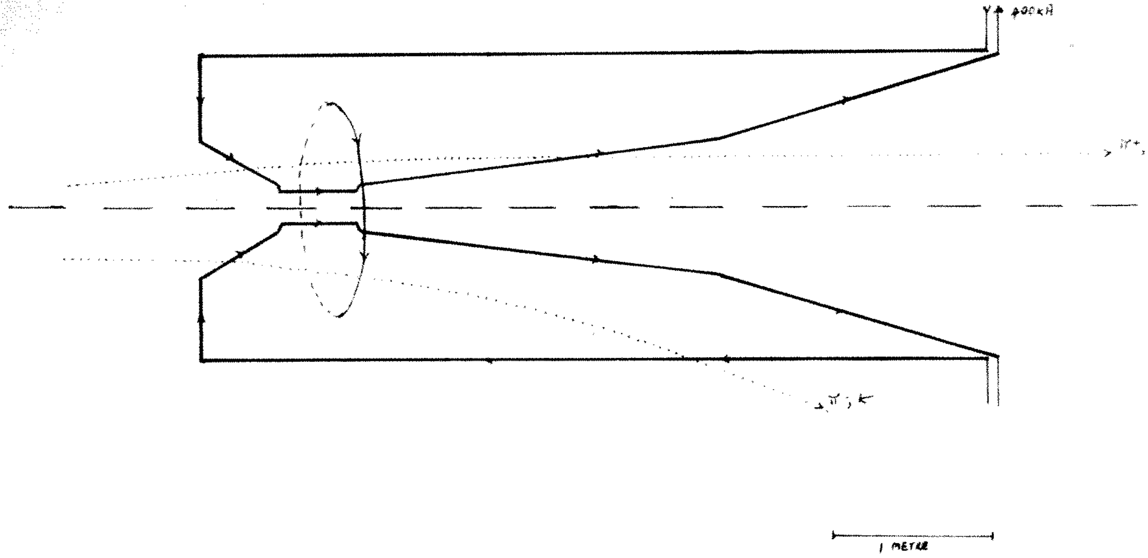

Fig. 3. Principle of the magnetic reflector. The major difference between this device and the magnetic horn shown in Fig. 1*a* is that the source of neutrino parents is some distance away.

of 300,000 A. With the current in the inner conductor in the direction of the neutrino parents, the magnetic field deviates the neutrino parents nearer to the axis, and the antineutrino parents further away, so that the neutrino flux at the detector is enhanced, and the antineutrino flux reduced to a very low value. At its narrowest place the inner cone is about 15 mm in diameter; such a conductor can carry a current of 300,000 A only momentarily. The mechanical shock, from the magnetic field and from the sudden heating by the passage of the current, produces such high stresses that a long development was needed, both for the magnetic horn and its energy storage system, to obtain the operating life of more than a million pulses necessary in an experiment.

The neutrino flux derived from the pions and kaons, produced from the extracted PS beam and focused by the magnetic horn, was almost two orders of magnitude higher in the experiments of 1963–64 than in the first neutrino experiment at Brookhaven. Thus it was possible to use a bubble chamber as a detector of neutrino interaction and a total of about 1,000 events in freon (CF_3Br) were photographed; a spark chamber of 30 tons operating at the same time recorded about 10,000 interactions. Many results were obtained, including a confirmation of the Brookhaven observation that ν_μ and ν_e carry independent quantum numbers. The ν_μ beam was contaminated by 0·5 per cent of ν_e, principally from kaons. The number of ν_e events was consistent with similar interaction cross-sections for ν_e and ν_μ, which was a new test of "μ–e" universality, not as precise as in decay processes, but in a quite different range of momentum transfer. From the statistics of the possible production of μ^+ by the ν_μ, it was concluded that any such interactions violating lepton conservation are less than 0·5 per cent of the total. There were several other conclusions, including that neutrinos from kaon parents seem to have the same properties as neutrinos from pion parents.

Of particular interest was the possibility of searching for the intermediate boson. Its expected signature was a muon pair in the spark chamber from the process $\nu_\mu + Z \rightarrow \mu^- + W^+ + Z$, followed in about 10^{-18} s by $W^+ \rightarrow \mu^+ + \nu_\mu$; or a μ^-, e^+ pair in the HLBC from $W^+ \rightarrow e^+ + \nu_e$, or perhaps pions from decay modes of the type $W^+ \rightarrow \pi^+ + \pi^0$ or $W^+ \rightarrow \pi^+ + \pi^+ + \pi^-$. No such evidence was found and it was concluded that, if the W as predicted exists at all, M_W must be greater than 2 GeV. To raise this mass limit appreciably requires neutrino beams of much higher energy.

From the bubble chamber data a preliminary determination was made of the nucleon form factors involved in the elastic interaction: $\nu_\mu + n \rightarrow \mu^- + p$. Although the neutron was bound in a nucleus of the CF_3Br, the analysis was valid because the muon escapes from the nucleus where it is produced without interaction and the proton has only a low probability of a disturbing interaction in the same nucleus. For pionic events the possibilities of analysis were much less favourable, since a pion is likely to be absorbed in the nucleus where it is produced. This aspect, together with clear evidence of a substantial inelastic event rate, made it obvious that the next experiment at CERN should investigate the neutrino interactions on free protons in propane in the bubble chamber.

To make such an experiment feasible, a new and substantial increase in the neutrino event rate was again imperative. It was achieved, partly by rebuilding the bubble chamber body to give a visible volume of 1·1 m³, and partly by constructing the new neutrino facility, depicted in Fig. 1. In this facility, the PS beam was extracted by the same apparatus as previously, but an entirely new system of elements for neutrino parent focusing was developed. The shielding was also rebuilt with provisions for monitoring the muon absorption. A new magnetic horn was designed with an efficiency about 1·3 times greater than the first one (unpublished results of D. H. Perkins and W. Venus). The essential modification, determined from more elaborate computer studies, was that parents were accepted from a longer, lighter target, actually of boron carbide instead of copper, as previously used. Particular attention was given to reducing the losses from interactions of the neutrino parents in the horn conductors, which they actually traverse. To focus the protons for the PS to a beam only 2 mm diameter at the horn target 90 m away was another essential requirement which has required much technical development. Some ten magnetic elements are pulsed simultaneously so that during the passage of the protons their guiding fields are precise to about 0·1 per cent.

The principal increase in the neutrino flux in the new facility has come from the invention of two toroidal lenses[8], called reflectors, which correct the trajectories of neutrino parents which are not focused adequately by the horn. The beam optical principles of the reflectors are similar to those of the magnetic horn. The essential developments have been to discover from computer studies that elements with such shapes, currents and locations can contribute so effectively to the neutrino flux, and then to excite them with the enormous currents required. Fig. 3 shows the principles of the first reflector.

The flux on the axis at the detector is inversely proportional to the shielding length. The best shielding therefore is the shortest consistent with sufficient stopping power, which for high energy experiments is determined by the maximum energy of the unwanted muons from the ν_μ parents. The disposition of the 6,000 tons of steel ingots, lent by the Swiss Government, and the many thousands of tons of concrete is shown in Fig. 1. For testing the synchronization and sensitivity of the neutrino detectors, mercury can be let out of an axial iron pipe to provide a controllable muon leakage through the shielding. The muon flux distribution can be scanned by detectors which can be moved in radial channels in the shielding. When the data obtained from these are finally reduced it will be possible to estimate a neutrino spectrum, which can be compared with that deduced from a knowledge of the parent production spectra in the target in the horn, the computed trajectories and the effects of absorption in the focusing devices. During the actual experiment, the muon monitoring equipment also enabled a rapid study of the optimum target material and best operation of the neutrino parent focusing elements. This CERN installation is at present the most intense high energy neutrino facility. In pulses 2 s apart about 10^{10} neutrinos traverse the detectors, to produce about five interactions per ton of material per hour.

For the first experiments in the new facility, in 1967, the 1·1 m^3 bubble chamber was used with propane, C_3H_8. Such a chamber installed in the experiment in which the existence of the two neutrinos was first demonstrated would have recorded only two events. In an allocation of accelerator time similar to that experiment about 1,000 events have been obtained in $1 \cdot 1 \times 10^6$ pictures. Simultaneously the PS beam was shared with several independent experiments, and the neutrino beam with two spark chamber experiments, the success of which depended on requirements which reduced markedly the maximum neutrino flux. About 80 per cent of the neutrino interactions in C_3H_8 are in carbon nuclei, but of those on free protons, about 100 will be good candidates for analysis as events of the type: $\nu_\mu + p \rightarrow \mu^- + \pi^+ + p$, shown in Fig. 4. By a kinematical study of the momentum unbalance, these events can be distinguished from interactions on bound protons in the carbon nucleus, which have appreciable Fermi momentum. For the final analysis a more refined fitting procedure will be used and a determination of the rate of production of N^*_{33} on free protons will be possible, together with a preliminary estimation of the appropriate form factors. Because of the more precise momentum determination possible in C_3H_8 compared with CF_3Br, the new bubble chamber data will permit a thorough re-examination of many of the conclusions of the 1963–64 experiments. The advantages of the lighter nuclei are, however, also accompanied by many disadvantages. The total event rate in C_3H_8 is only about 0·3 of that in CF_3Br and the manifestation of γ-rays is much rarer. Because the surroundings of the chamber and the shielding were of the same density in both series of experiments, the ratio of interactions due to neutral particles in equilibrium with the neutrino flux, to true neutrino interactions, is higher in C_3H_8 than in CF_3Br. This reduces the certitude of identification of events in propane. It is evident that in future experiments, according to the particular features of the interactions which are being studied, both heavy and light working fluids in bubble chambers will each have their useful roles.

Spark chambers operated in association with the bubble chamber will elucidate two further questions. The first question is—does the ν_μ ever produce a μ^+ instead of a μ^-? From the previous experiments this happens less than once in a hundred times. The present data should explore a much lower limit. For this aspect of the operation part of the neutrino shielding was defined as a target for ν_μ interactions by means of a scintillation counter. Emerging particles were located by a spark chamber, the charge of those which traversed the bubble chamber was identified and their range determined in the subsequent spark chambers; thus muons could be distinguished from pions, and μ^- from μ^+. During most of the operation an absorber was placed in front of the target in the magnetic horn to eliminate antineutrino parents which otherwise would not have been rejected by the focusing fields. The spark chamber group is at present analysing the relative significance of the residual muon leakage through the shielding, $\bar{\nu}_\mu$ interactions and any possible production of μ^+ by ν_μ. The other question it is investigating with the same installation is how the total neutrino interaction cross-section depends on the atomic weight of the interacting nucleus. This is done by measuring the interaction rate per unit mass in plates of carbon, iron and lead in the spark chamber array.

The equipment already under construction and the developments foreseen will increase event rates by such large factors that neutrino experiments will become a major

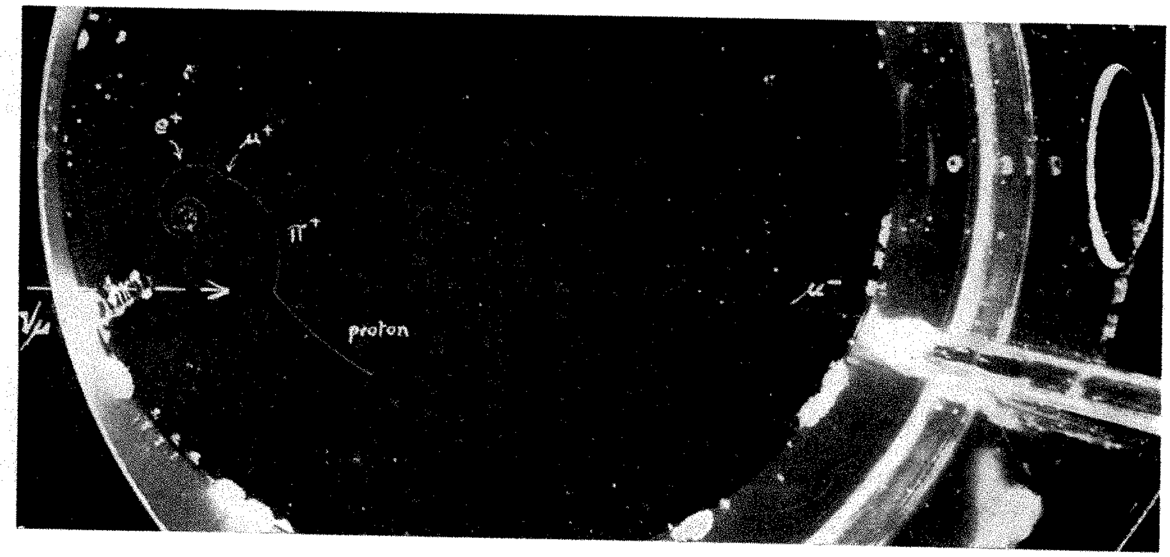

Fig. 4. Candidate for an interaction of a ν_μ of energy 2·62 GeV with a free proton $\nu_\mu + p \rightarrow \mu^- + \pi^+ + p$. The μ^- leaves the chamber, the proton is the heaviest track and the decay of the pion at rest ($\pi^+ \rightarrow \mu^+ + \nu_\mu$, $\mu^+ \rightarrow e^+ + \nu_e + \nu_\mu$) can be seen as the middle track.

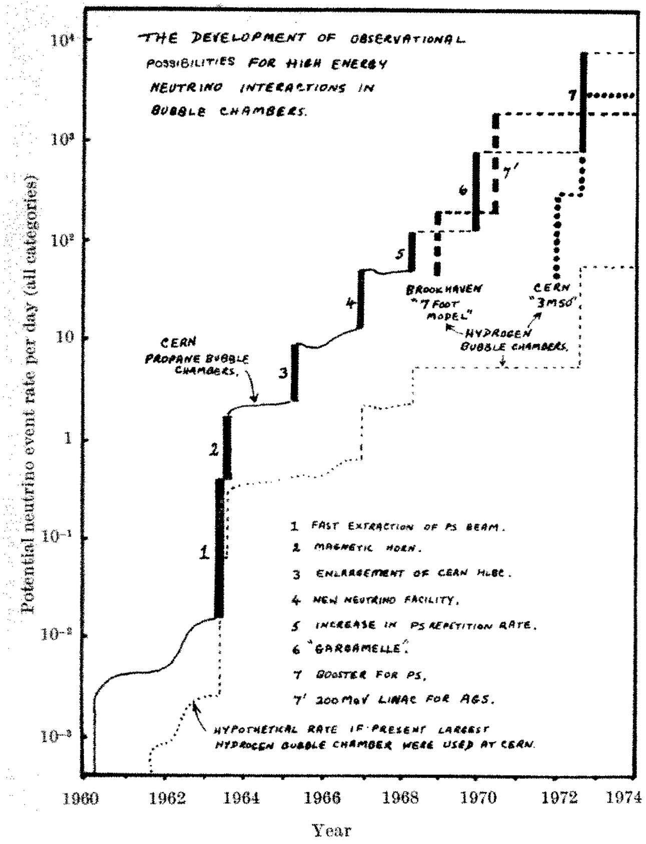

Fig. 5. Potential neutrino event rates at the PS and AGS: The diagram refers to the propane and hydrogen bubble chambers. The steps represent the various contributions to the event rate and already planned future developments. No account is taken of possible improvements in the accelerated proton beam except for the new injectors, or for possible improvements in neutrino parent focusing devices.

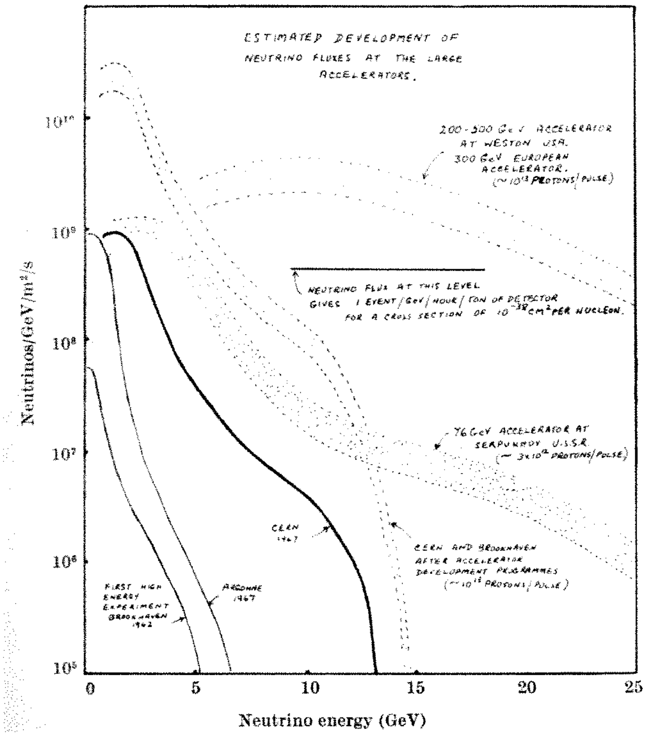

Fig. 6. Estimated development of neutrino fluxes at the large accelerators: The fluxes already used in three experiments are shown together with tentative estimates of the future fluxes for the accelerator intensities shown. A spectrum at the level indicated produces one event per GeV, per hour, per ton of detector for an interaction cross-section of 10^{-38} cm² per nucleon.

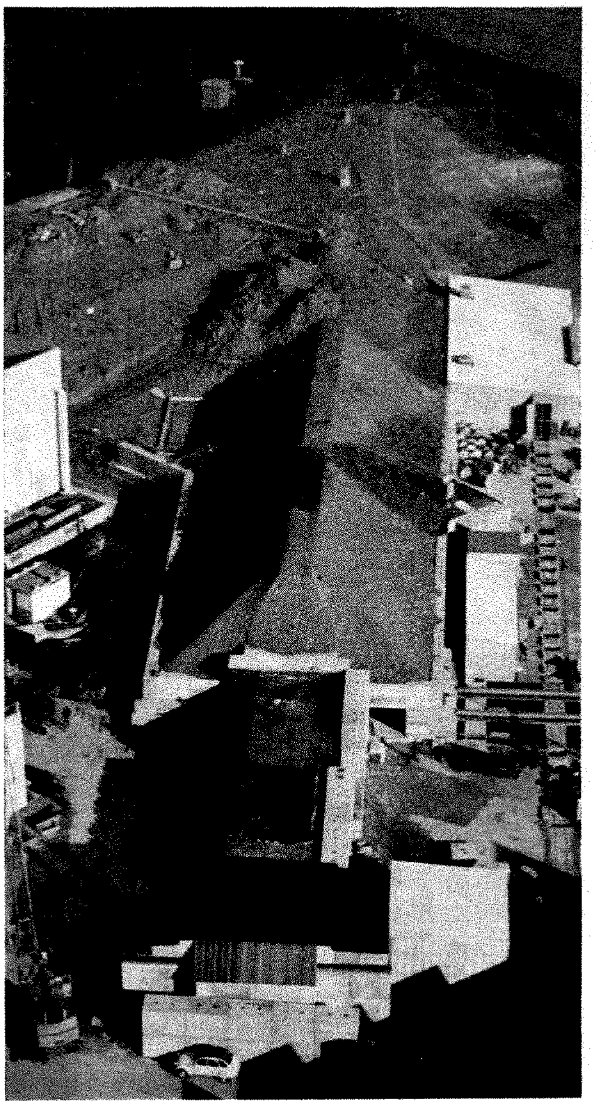
field of high energy physics. The AGS and the PS have development programmes to raise their intensities. Both accelerators will have new power supplies to increase the cycling rate of their magnet systems and both will have new injectors. A factor of twenty in the average extracted proton current will be gained within five years, with a corresponding gain in neutrino fluxes. A neutrino experiment is first priority on the experimental programme of each of the very large bubble chambers being built for the AGS, PS and ZGS. Gargamelle, the 10 m³ heavy liquid bubble chamber being constructed for CERN by the French Atomic Energy Commission, will increase the neutrino detection efficiency by a factor of about 7 compared with the present 1·1 m³ chamber. The half scale model of the projected "14 ft." hydrogen bubble chamber for the AGS will probably be operational near the end of this year. After testing, it will be used immediately for a neutrino experiment, probably with a deuterium filling, which will permit a refined study of form factors both in the process $\nu_\mu + n \rightarrow \mu^- + p$ and $\nu_\mu + p \rightarrow \mu^- + \pi^+ + p$. A great advantage of these larger chambers will be the increased efficiency of identification of the high energy reaction products. The previous results, which cannot be regarded as other than preliminary, will be improved by



Aerial view of the CERN neutrino facility: The annular earth covered tunnel of the 25 GeV PS can be seen at the top left. The neutrino beam tunnel is also earth covered, for radiation protection, and leads to the 6,000 ton shielding of steel ingots and finally the bubble chamber block-house in the foreground. (CERN Photo 115-10-66.)

the better statistics. A hundred-fold increase in the present event rates will probably be sufficient to study the polarization of some of the reaction products. With a thousand-fold increase it may be possible to study the neutral interactions of neutrinos: $\nu + e \rightarrow \nu + e$ and $\nu + p \rightarrow \nu + p$, which have never yet been seen but which are predicted to take place. Success will depend crucially on a detailed and accurate understanding of the background due to the neutral particles which are in statistical equilibrium with every neutrino beam passing through shielding material. The development of bubble chamber observations of neutrino events is shown in Fig. 5.

In parallel with the increases in neutrino event rate which the new developments will bring, neutrino beams with a smaller spread in energy[9] will be feasible. Until now the parent focusing devices have been designed to produce broad spectra, but given sufficient event rates neutrino beams with a narrow energy spectrum are also possible. The usefulness of such beams will depend greatly on what will be learned about neutrino interactions. It is of the greatest interest to experiment with higher energy neutrinos because at this stage even a knowledge of the variation of the total interaction cross-section with energy is of fundamental theoretical importance. The next major extension of laboratory neutrino spectra will be made at Serpukhov[10] which now has the highest energy proton accelerator in the world. If the mass of the W is less than 3 GeV, and its properties are as predicted, it can be found at Serpukhov. The interaction $\nu_\mu + e^- \rightarrow \mu^- + \nu_e$, which has a threshold of about 10·7 GeV, should be seen for the first time at Serpukhov. A less spectacular but extremely important aspect of the Serpukhov neutrino spectra will be the high flux in the region above 5 GeV which is also accessible at CERN and Brookhaven. At Serpukhov, given adequate facilities, it will be possible to obtain data equivalent to that of all preceding experiments in this region in a very short time of operation. Somewhat further into the future will be the neutrino facilities of the American 200–500 GeV proton synchrotron already being planned at Weston near Argonne, and the possible European 300 GeV accelerator. From such accelerators, very high neutrino fluxes[11] can be derived as shown in Fig. 6. With the detectors foreseen, total event rates 10^3 to 10^4 times greater than those possible today will be feasible. In this field, where even Pauli misjudged the future, it is improbable that we can foresee the problems which will be studied in the future. We know instinctively, however, that the new observational possibilities will lead to profound contributions to the understanding of the interactions of these particles, which seem to be the most abundant material constituent of nature.

Recent progress in the fields of magnetic circular dichroism (MCD) and magneto-optical rotatory dispersion (MORD) is reviewed and these techniques are contrasted with those of natural circular dichroism and optical rotatory dispersion. Apart from the fact that MCD and MORD do not require optically active compounds (optical activity being induced by the magnetic field), these physical tools offer spectroscopic information which is different or impossible to obtain by other means.

OPTICAL rotatory dispersion (ORD)[1] and circular dichroism (CD)[2] have become important tools in organic, inorganic and biological chemistry for the solution of many structural and stereochemical problems. This, in turn, has stimulated renewed interest in the phenomenon of magnetically induced optical activity[3,4] (the Faraday effect), which can be produced in all substances by exposure to a properly oriented magnetic field, whereas ORD and CD are applicable only to substances possessing natural optical activity. It will be shown that the utility in chemistry of magneto-optical rotatory dispersion (MORD) and magnetic circular dichroism (MCD) is quite different from that of ORD and CD.

The principle of the Faraday effect is illustrated in Fig. 1. Left (L) and right (R) circularly polarized light (for the sake of convenience plane polarized light is employed because it is equivalent to the sum of the R and L circularly polarized components) is passed through a medium, and a magnetic field (H) is applied along the direction of propagation of the light beam. Because the magnetic field possesses helical symmetry, circular dissymmetry will be produced in the medium with the result that a different response will be elicited by optical stimulation with right and left circularly polarized light. Consequently, the refractive indices (n_L and n_R) as well as the molar extinction coefficients (ε_R and ε_L) will be different for the two (L and R) circularly polarized components. The angle α, which is proportional to $n_L - n_R$, is called the magneto-optical rotation, while $\Delta\varepsilon = \varepsilon_L - \varepsilon_R$ refers to the magnetic circular dichroism.

The magnitude of the Faraday effect phenomenon is proportional to the intensity of the magnetic field. In

order to obtain maximal signals with a minimum of material the most recent experiments[5-9] have been conducted with superconducting magnets capable of field strengths in the neighbourhood of 50 kgauss. Experimentally the same instruments are employed for the measurement of MORD and MCD as for ORD and CD, the only requirement being that the sample compartment is of sufficient size to accept the appropriate magnet. The spectacular success of ORD with naturally optically active compounds has been associated with measurements performed through the region of the relevant absorption bands of the appropriate compounds, thus leading to anomalous dispersion (the well known "Cotton effects"[1]). Similarly, the most interesting results in MORD work[10,14] have been encountered in the region of maximum absorption. In the case of CD or MCD, this is an absolute requirement, because no circular dichroism is encountered outside the region of the absorption bands. Because most measurements are performed in solution utilizing optically transparent solvents (water, methanol and iso-octane, for instance), the MCD signals will only be associated with the absorption bands of the solute. On the other hand, magneto-optical rotation (related to refractive index, rather than just absorption—see Fig. 1) is also observable outside an absorption band, so the solvent also becomes optically active and its contribution must be subtracted from that of the solute in order to obtain the latter's MORD curve. This is one of the reasons why MCD is generally preferred over MORD.

Characteristics of MCD and MORD Spectra

In order to illustrate the areas of chemical applications, it is first necessary to point out the main features of the spectra encountered in measurements through absorption bands, MCD rather than MORD being chosen for the sake of convenience. The phenomenon is associated with an electronic transition, that is, with the promotion of an electron from the ground state to an excited one. An account of the dispersion curves can be given by considering the perturbation by the magnetic field of the various states and electronic transitions. In the absence of a magnetic field, a given transition at frequency ν_0 (Fig. 2*a*) gives rise to a corresponding absorption band (Fig. 2*b*). When the magnetic field is turned on, however, three perturbations are produced.

(1) The ground state may be split (in paramagnetic materials) and lead to two sub-levels; theory then predicts that the R and L circular absorption components occur at frequencies $\nu_0 - m_G H$ and $\nu_0 + m_G H$, respectively, where m_G is the so-called magnetic moment of the ground state, the magnitude of the splitting being $2H$ times m_G.

(2) R and L components have different probabilities of transitions, one being $\varepsilon_m(1 - aH)$ and the other $\varepsilon_m(1 + aH)$, because the perturbation is linear with the field.

(3) The sub-levels in the ground state have a different population, for example, 1 for the lower and $1 - 2m_G H/kT$ for the upper (according to the Boltzmann law). ε_L and ε_R can now be expressed as shown in Fig. 2*c* and the resulting expression for $\Delta\varepsilon$ becomes

$$\Delta\varepsilon = \varepsilon_L - \varepsilon_R = 2\varepsilon_m H \left\{ -m_G \frac{\mathrm{d}f}{\mathrm{d}\nu} + \left(\frac{m_G}{kT} + a\right) f(\nu) \right\}$$

In general, however, the excited state can also be split by the field, with a corresponding m_E value. It can then be easily established that $\Delta\varepsilon$ becomes

$$\Delta\varepsilon = 2\varepsilon_m H \left\{ -(m_G + m_E) \frac{\mathrm{d}f}{\mathrm{d}\nu} + \left(\frac{m_G}{kT} + a\right) f(\nu) \right\} \qquad (1)$$

This formula is similar to that obtained by more refined treatments[4].

Three important results follow. First, it shows that $\Delta\varepsilon$ is proportional to H. Second, an MCD experimental dispersion curve can be mathematically analysed as a linear combination of the absorption curve (this term often being referred to as $B + C/kT$) and its first derivative (A term). In other words, an MCD curve resembles a bell-shaped or an S-shaped curve, depending on the relative magnitude of the two terms (see, for example, Fig. 3). Third, B and C/kT can only be separated by measurements at various temperatures because they have the same frequency dependence. As in the case of natural optical activity[1,2], there is a Kronig–Kramers (K.K.) relation between MCD and MORD. The angle of rotation, α, is therefore expressed in a manner similar to $\Delta\varepsilon$, the K.K. transforms of $f(\nu)$ and $\mathrm{d}f/\mathrm{d}\nu$ being substituted in equation (1) and every other term being left unchanged. It follows that the MCD and MORD curves (for relationship, see Fig. 3) provide the same information, namely, the magnitude and sign of the three parameters A, B and C. It should be stated, however, that they are more easily extracted from MCD curves[6].

Comparison of Natural and Magneto-optical Activity

Equation (1) is appropriate for describing natural as well as magneto-optical activity. In the former case,

however, the B term only is non-zero—that is, a CD curve has the typical bell-shape. It is then clear that MCD provides new information through the A and C parameters. Moreover, it should be kept in mind that CD and MCD are of a different physical origin[11] and that the quantum mechanical expression of B is different in the two cases. This aspect can be illustrated by considering an inherently symmetric chromophore, in which optical activity is induced by disturbance from a dissymmetric substituent which does not form part of the chromophore itself (a typical example being the saturated carbonyl group[1,2]). Such a chromophore is very sensitive to the relative position of the substituent and the extrachromophoric part of the skeleton. This is why the sign and magnitude of the ORD and CD Cotton effects are so dependent on the conformation of the molecule and why ORD and CD have found such utility in stereochemistry. This does not apply to magneto-optical activity because the circularly dissymmetric perturbing field (leading to B terms) is now external and not inherent to the molecule. One can therefore predict that MORD and MCD will not usually be useful in the solution of conformational problems. This does not mean that Faraday effects are useless for solving chemical problems. Two examples bearing on this question will be considered briefly, one referring to an optically active and the other to an optically inactive substance.

In Fig. 4 the circular dichroism[6] of a chlorophyll-like molecule is reproduced without and with a magnetic field. It is clear that MCD signals are here far more intense than CD ones. Moreover, it has been established that the magnitude of the MCD peak around 539 nm depends considerably on the nature of the substituents attached to the skeleton. A similar conclusion can be reached from the MCD spectra (Fig. 5) of two optically inactive corrins[12] related to vitamin B_{12} in which the MCD peak at

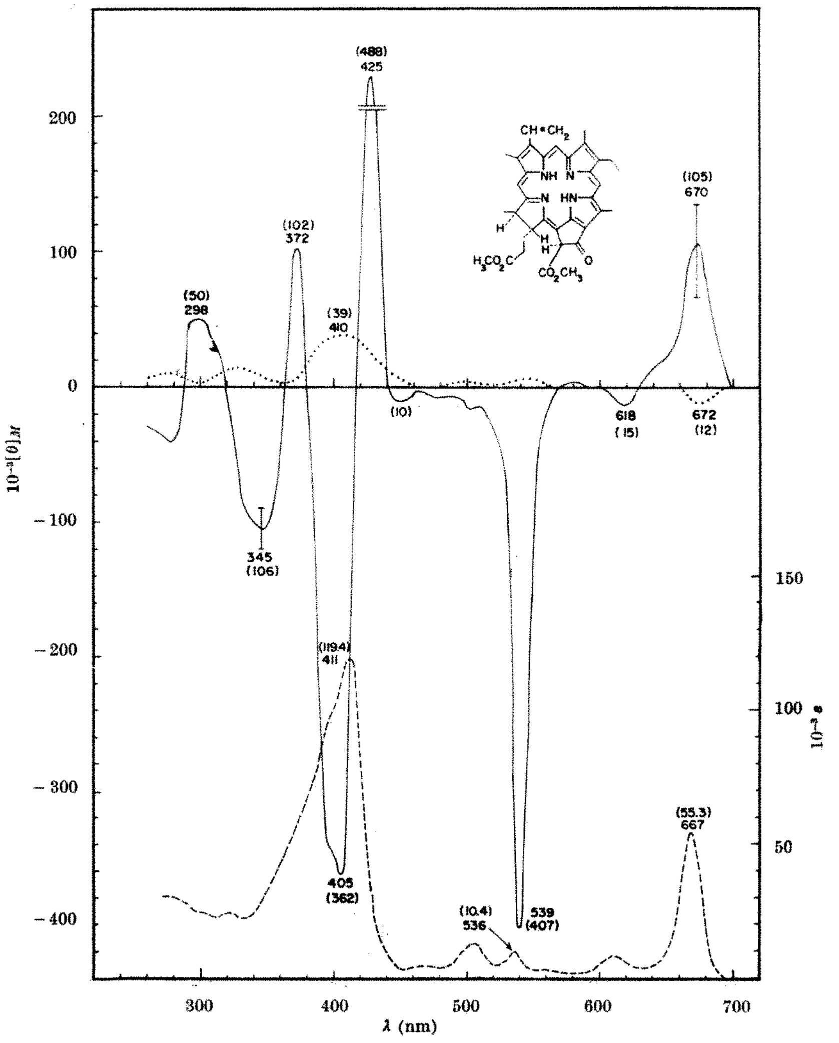

Fig. 4. Absorption (– – –), circular dichroism (. . . .) and magnetic circular dichroism (———) of methylpheophorbide a. MCD $[\theta]_M$ is reported for a 41·7 kG magnetic field. (Taken from ref. 6.)

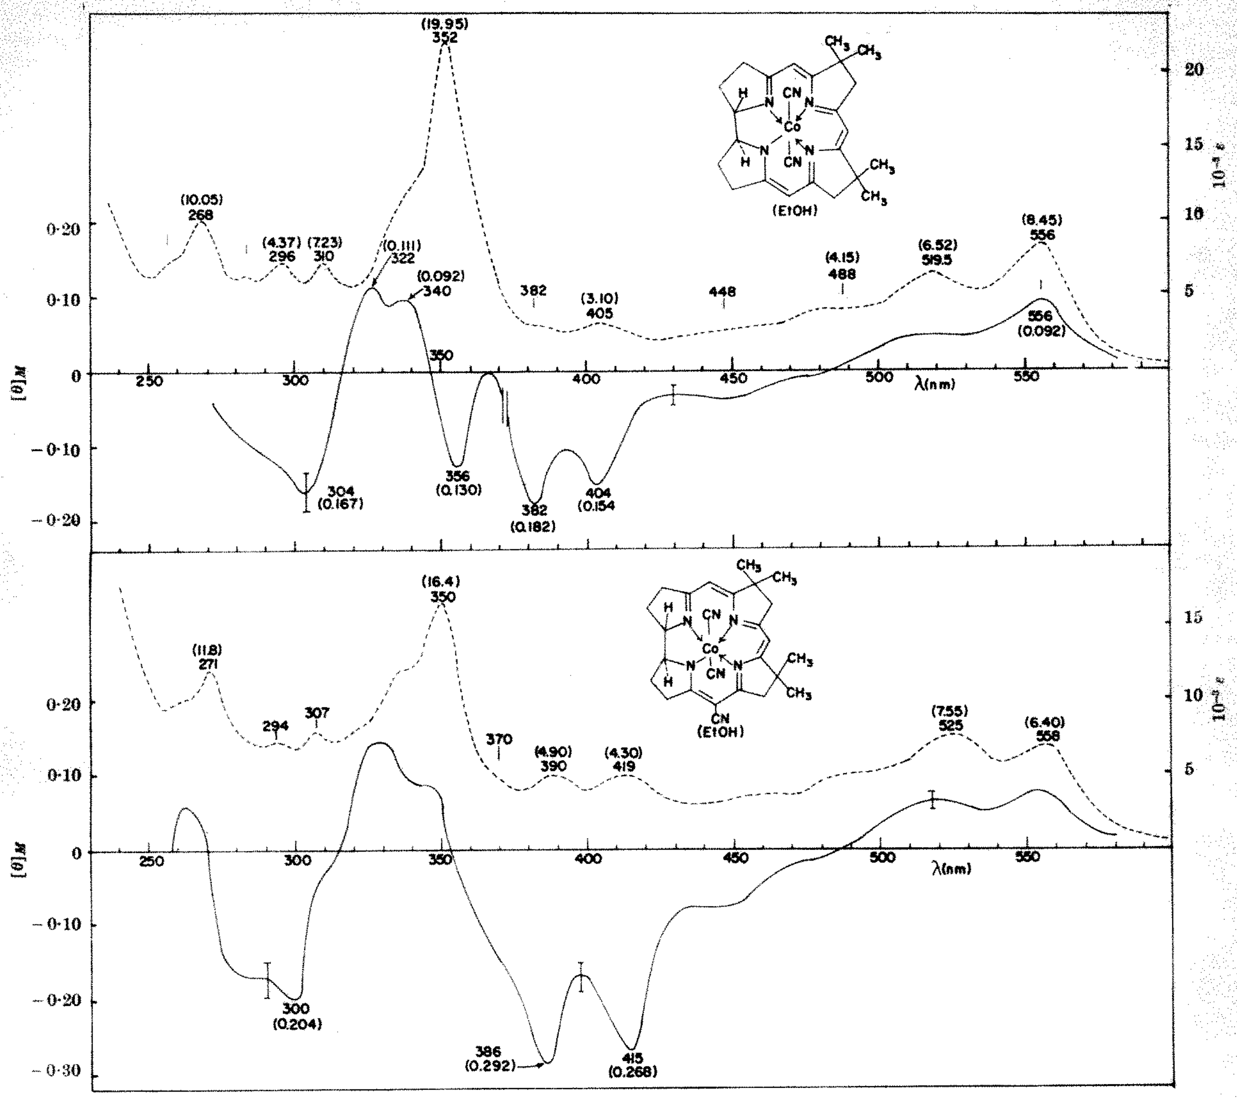

Fig. 5. Magnetic circular dichroism (———) and absorption spectra (– – –) of two optically inactive corrins.

356 nm disappears when one of the nuclear hydrogen atoms is replaced by a cyano group.

Unpublished studies in the nucleotide field by Voelter, Bunnenberg and Djerassi have also demonstrated the utility of MCD measurements with optically active as well as inactive molecules. The CD signals of optically active nucleosides and nucleotides are greatly magnified in the presence of a magnetic field (similar to the example of Fig. 4), so that one can obtain good MCD curves with quantities of material on which no CD signals can be discerned. The analytical and structural implications of such results are obvious. Furthermore, the MCD curves of the optically inactive purine and pyrimidine bases corresponding to these nucleotides and nucleosides can also be employed for purposes of structural differentiation, whereas ordinary CD or ORD cannot, of course, be employed because of the lack of natural optical activity.

Some Spectroscopic Applications of MCD and MORD

The utility of Faraday effect measurements can be demonstrated by considering again equation (1), and by comparing them with a few other techniques. The *C* and *A* terms allow the magnetic moment of the ground or excited states to be determined experimentally, *C* referring to the ground state only. The absolute value of *C* is already known from electron paramagnetic resonance (EPR) measurements, but its sign depends greatly on the nature and symmetry of the excited state corresponding to a given electronic transition. MCD and MORD therefore constitute a very powerful tool for aiding in assigning excited states. As shown recently in the case of the ferricyanide ion[8], this offers a new challenge to the study of charge transfer transitions. The *A* term is especially useful when it demonstrates the presence of a magnetic moment in the excited states. This is of great value because EPR—except for a few occasions—does not provide information on excited states. Zeeman effect measurements, which would solve such a problem, are limited to very sharp lines (gas or crystals at very low temperature) while Faraday effect measurements are possible on wide absorption bands, even at room temperature. Already a number of practical applications of these observations have been published pertaining to the assignment of excited states[8,9] and to the experimental determination of their magnetic moments[7,9]. These data allow in turn a quantitative verification of various molecular orbital calculations and constitute significant support for the theoretician. It is worth emphasizing that the substances studied so far range from inorganic complex ions to biological systems or complex conjugated organic molecules. Several general conclusions have been drawn from recent experimental work. It has been shown that the *A* and/or *C* terms are predicted to be non-zero in the case of molecules or complex ions possessing at least a three-fold axis of symmetry. Their sign and absolute value can be determined for allowed electronic transitions from group theory and quantum mechanical calculations respectively. On the other hand, the *B* term is the only one expected when the symmetry is lower, which is actually the case for most molecules. Theory then predicts[11,13] the *B* term to be large when two energy levels exist strongly coupled by the magnetic field and close together, while each of them is coupled to the ground state via an electric dipole moment. Group theory again shows that a large number of molecules, relevant to both chemistry and biology, exhibit such properties. Recent examples include various (ten) annulene systems[13] and vitamin B_{12} derivatives[12]. Although *B* is very difficult to estimate theoretically, its existence (and its sign) or non-existence is very significant by itself. For example, absorption bands which are hidden in the absorption spectrum can sometimes be revealed in the MCD spectrum[13]. Furthermore, the sign of the *B* terms permits the relative polarization of electronic or vibrational absorption components to be predicted or verified.

No attempt has been made to review all the recent MCD and MORD studies[14–16] of organic and inorganic compounds. Judging from the ever increasing tempo of activity in this field since 1965, one may anticipate rapid advances, and because there is practically no overlap between ORD and CD on the one hand, and MORD and MCD on the other, it is likely that the latter two techniques will soon be added to the instrumental repertoire of many chemists. Fortunately, this requires only the addition of a suitable magnet to existing instruments rather than the purchase or construction of completely new ones. In view of the wide distribution of spectropolarimeters and circular dichroism instruments, publications on many different types of compounds from numerous laboratories will surely be forthcoming with concomitant broadening of the scope of these two techniques.

We thank Mr A. M. Babcock for assistance with the figures and the US National Science Foundation for financial support.

Native Australian and introduced species of animals are adapted to severe sodium deficiency. Effects of such a deficiency are aggravated by pregnancy and lactation, and it has been shown that mechanisms controlling sodium homeostasis in wild rabbits are subject to profound stress.

THERE are many reports of wild animals exhibiting an appetite for salt in nature, but there are few data concerning the metabolism of these animals which would establish beyond doubt that they are, in fact, salt depleted.

Stags, deer, chamois and other plant eaters are reported to have licked out caves in the salty slates of the Altai Mountains[1], and hunters lie in wait for them near salty pools, as they do with kudu and other buck near salt licks in Africa[2]. Rooseveldt elk and deer, bighorn sheep, goat, moose, caribou, mule deer and white tailed deer all seek out natural dry or wet licks in the Rocky Mountains in spring or summer or are attracted to salt blocks[3,4].

Game expose themselves to predation by black and grizzly bears and mountain lions when they leave open country and traverse the trails leading to licks. As many as 200 elk collect in a day at licks in Idaho. Cows and yearlings are most numerous at licks which are usually not shared, and the dominant bull elk exercises choice. Fighting occurs, and elk drive deer away and are themselves displaced by cattle[3]. Analyses of Canadian licks showed a high sodium content but other trace metals were present. In Montana only three of twenty-five potential licks were used by wild ruminants, and sodium bicarbonate and sodium sulphate were the only compounds significantly more abundant in these licks[5]. In Alaska, snow shoe hares will gnaw wood which has been immersed in salt water, and other animals will damage buildings where wood has been impregnated with salt from evaporated urine (personal communication). Reindeer are reported to drink sea water, and sheep made sodium deficient in the field by a unilateral parotid fistula will selectively graze plants with a high salt content[6]. Schaller observed that, on occasions, mountain gorillas ate soil which, on analysis, showed a high salt content[7].

Cattle and kangaroos in the mountains of south-eastern Australia exhibit an appetite for salt, and Bott *et al.*[8] showed that cattle which were eating pasture with only 1–2 mequiv. of sodium/kg wet weight excreted urine that was virtually free of sodium, and had a reduced salivary ratio of sodium to potassium indicative of increased aldosterone secretion. Myers[9] has found that a large increase of the zona glomerulosa occurs in the adrenals of wild rabbits in sub-alpine and sub-tropical regions, and that this can be associated also with the formation of cortical nodules. In the alps, these striking adrenal changes occurred in spring and early summer, and were associated with an avid appetite for wooden pegs impregnated with various salts. Sodium chloride and $NaHCO_3$ were particularly attacked, and some gnawing of $MgCl_2$ and KCl occurred if the pegs were exposed over a long period.

This article describes an attempt to analyse comprehensively the spectrum of adaptations by both native Australian and introduced species of animals to ecological conditions involving severe sodium deficiency. The studies of behaviour, physiological and biochemical processes, and morphology were made in the Snowy Mountains of southern Australia—an area larger than Switzerland—where analyses of soil and plants showed that the environment was severely sodium deficient. Control observations on similar parameters were made on an ocean coast region of Victoria, where the high sodium content of rain water provided vegetation with a high sodium content, and in a desert region near Broken Hill, central Australia, where the salt content of vegetation was high. A temperate grassland region with a moderately low salt content near the national capital, Canberra, was also studied. A principal aim was to evaluate salt appetite in relation to the verified sodium status of the animals as reflected by sodium excretion, and also the hormone secretory processes which are concerned with sodium balance. We have found some striking morphological changes concurrent with the functional observations. Some interesting seasonal, as well as regional, differences have emerged in relation to the alpine areas.

In examining the physiological effects of, and adaptive

* Hard pellets are normal faeces voided directly onto the ground. Soft pellets, resulting from caecal fermentation, are eaten from the anus.

reactions to, a sodium deficient environment, it may be noted that, if the sodium content of the diet is virtually nil, conservatory processes may not be adequate to avoid a progressive depletion of body sodium. There may be species differences in this respect. Cattle are more prone to suffer severely from sodium deficiency because of the high sodium content of their semi-liquid faeces[10] than sheep which are able to reduce faecal sodium content to very low levels when sodium depletion supervenes[11].

The effect of a sodium deficient environment is aggravated by pregnancy and lactation, because of sodium accumulated in the growing products of conception and the augmented blood volume, and sodium lost in milk[12]. The stress can also be increased by any intestinal disturbance of microbial or nematodal origin, which jeopardizes the efficiency of sodium absorption from the gut[13], or results in sodium sequestration in the nematodal parasites.

Seasonal variation in the characteristics of vegetation, such as the onset of lush spring growth, can result in a rapid reduction in the sodium content/unit weight of vegetation, a decreased sodium to potassium ratio and sodium content/calorie of intake, and increased fluid turnover. In this context, it has been suggested that a high rate of potassium excretion causes some sodium loss[14]. If the sodium deficient areas are in the tropics, and temperature regulating mechanisms are stressed, according to the species, there is some sodium loss from skin in sweating or from saliva as a result of drooling associated with panting[12].

Christian (personal communication) has proposed that a high population density increases the size and activity of the zona fasciculata and reticularis, and that the high glucocorticoid secretion causes natriuresis and kaliuresis. Glucocorticoids may antagonize the sodium-retaining effect of aldosterone in adrenalectomized rats[15]. This renal effect would further aggravate the effects of a low sodium environment, and the trophic effects on the fasciculata–reticularis may possibly limit the functional capacity of glomerulosa to hypertrophy in response to sodium deficiency. Aumann and Emlen[16] have reported that the sodium level of soil and the density of populations of microtine rodents are directly related, and concurrent laboratory experiments showed increased salt intake of microtine groups in response to crowding.

The studies on the various biological parameters indicative of overall adaptation by the organism to differing ecological conditions were made on introduced species—wild rabbits *Oryctolagus cuniculus* (L.) and sheep—and on native animals—wombats *Vombatus hirsutus* (Perry) and kangaroos *Macropus giganteus* (Shaw). One principal aim was to measure the concentration of steroids in peripheral blood by using recently developed highly sensitive methods of double isotope dilution derivative assay[17]. Laboratory experiments[18] on the time course of action of ACTH following direct adrenal arterial infusion have shown that 2–3 min elapse before a significant rise of corticosteroid secretion in adrenal venous effluent. In order to obtain a measurement in conditions where the concentrations were not modified by probable pituitary stimulation associated with pursuit and capture of wild animals, it was considered that the most practical approximation to the normal would be achieved by locating the nocturnal grazing animals by spotlight from a travelling car, instant killing by shooting through the brain, and immediate withdrawal and frozen storage of cardiac blood. In these conditions, the peripheral blood level should reflect that of the grazing animal before disturbance.

Table 1 shows the analyses of soil and mixed grasses from the regions which were studied. With the Snowy Mountains, seasonal analyses were made. The higher sodium content of soil and grasses in the desert and on the sea coast is evident. Very low sodium content of grass was found in the Snowy Mountains in spring and summer. The exceptional observation in the spring was on an area where a bush fire had burnt 2 years previously. The sodium content of grasses was greater in the mountains in autumn and winter. One species of plant, *Stylidium graminiforum*, the seeds and other parts of which were eaten by rabbits in autumn, had a high sodium content. In relation to the alpine figures (*c.* 1 mequiv./kg wet weight) approximately a week's intake of food by a sheep or rabbit is required to provide up to 5 per cent of the sodium content of the circulating plasma whereas, on normal pasture, sodium equivalent to 10–25 per cent of the plasma content is ingested each day. At birth, a rabbit weighs about 40 g and total body sodium is about 5 mequiv. Subsequent to birth a litter of four rabbits each grows about 9 g/day. If the doe provides 100 g milk of normal composition/day, of which the ash content is 2·5 per cent and sodium is 5 per cent of the ash[19], it may be calculated that 20 per cent of the sodium content of circulating plasma would be required each day if lactation were normal. The profound stress on mechanisms controlling sodium homeostasis is evident from the following data.

Table 2 shows that in spring and summer the mountain rabbits excreted urine which was virtually free of sodium whereas, in autumn and winter, urine contained 2–6 mequiv./l. Correspondingly, the sodium content of hard and soft faeces was much lower than in the desert region. Fig. 1 shows that the sodium content of urine of kangaroos and wombats in the alps was virtually nil compared with that of sea coast animals—kangaroos a mean of 215 mequiv./l. and wombats 23 mequiv./l. The lower sodium content of the urine of the sea coast wombat possibly reflects different habits of the latter as root eaters. A large unexplained variation was found in urinary sodium content of sheep grazing in the mountain areas in early summer (from 0·3 to 130 mequiv./l., $n = 14$); this requires further investigation in relation to the possibility of selective grazing of plants or access to an undetected source of salt.

Only limited observations of blood electrolytes were made. The mean sodium content of plasma of the alpine kangaroos—139 mequiv./l.—was reduced relative to the sea coast animals—148 mequiv./l.

Table 2 shows that the concentration of peripheral blood aldosterone was greatly increased in the alpine rabbits relative to that of the desert and Canberra grassland animals. The highest aldosterone levels were found in pregnant animals during the spring in the alps.

As reported in detail elsewhere[20], the four mountain kangaroos which were examined had a mean aldosterone concentration (40 ng/100 ml.), four times that found with nine plain and sea coast animals—9 ng/100 ml. (Fig. 1). The mean aldosterone in the five mountain wombats (12·5 ng/100 ml.) was double that of the sea coast animals (6 ng/100 ml.)—both small groups included observations with very low levels. Cortisol and corticosterone were present in the blood of both species, cortisol being present in the larger amount. There was little difference in the levels of glucocorticoids in the sodium deficient and sodium replete animals.

Sheep in the alpine areas were anaesthetized, the parotid ducts were cannulated and saliva was collected. Adrenal vein blood was collected from the cannulated adrenal vein. Consistent with the unexplained variation of the concentration of urinary sodium referred to here, the secretion rates of aldosterone varied from the usual range of sodium replete anaesthetized sheep to levels seen in severe depletion (that is, from 1·7 to 15·6 μg/h), the high value being associated with virtual absence of sodium from urine and a large reduction of salivary sodium to potassium ratio.

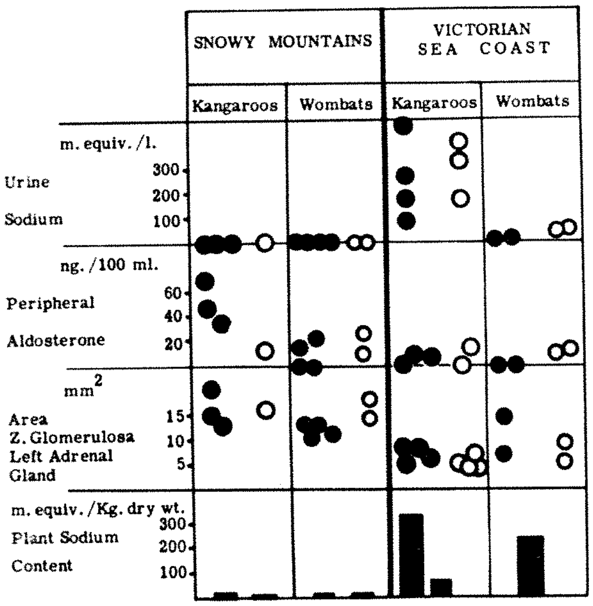

Fig. 1. The urinary sodium concentration, peripheral blood aldosterone and percentage of adrenal area represented by zona glomerulosa in two marsupial species—the grey kangaroo and the wombat studied in an alpine and a sea coast area.

The concentration of renin was measured in the kidney cortex[21]. In rabbits (Table 2) the mean concentration (U/g) was greatly elevated in the alps in spring and summer. Highest values were recorded in females—possibly suggesting, as with aldosterone values, the additional stress on sodium balance of the reproductive process. The mean value for animals from the Canberra grasslands area was slightly higher than for desert animals.

As with rabbits, kangaroo and wombat kidneys were incubated with prepared sheep substrate[21]. The concentrations were less than 1 U/g, which may be caused by species specificity of the renin/renin substrate reaction. The kidneys of sheep in the alps had renin levels in the high normal range but no values were found near to those found in laboratory animals which were sodium depleted by a parotid fistula.

Table 3 shows that the adrenal glands of the alpine rabbits in spring were heavier than in other regions, and

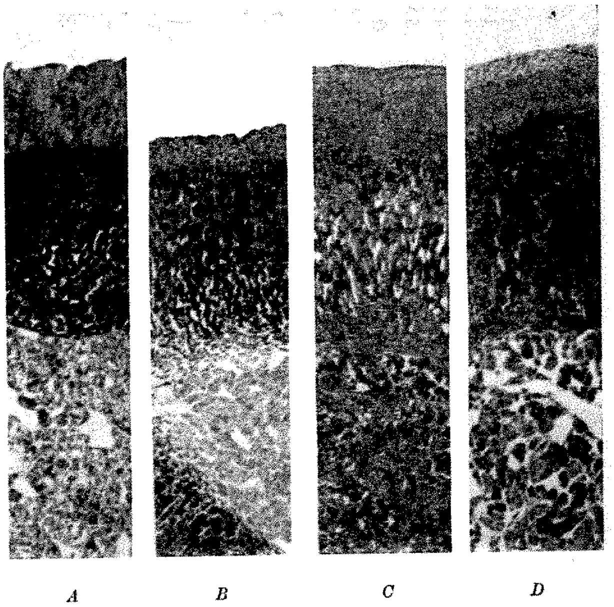

Fig. 2. Section of the adrenal glands of the kangaroo (*Macropus giganteus* (Shaw)), (*A*) sodium deficient, (*B*) sodium replete, and the wombat (*Vombatus hirsutus* (Perry)), (*C*) sodium deficient, (*D*) sodium replete. The zona glomerulosa is wider in deficient animals. The capsule is more prominent in the wombat adrenal. (× 27.)

that seasonal variation occurred in the alpine animals. The area of zona glomerulosa represented a much greater percentage of the total area of the adrenal in the alps in spring and summer than in the desert and grassland animals. The adrenal glands of *Macropus* (1·1 g) and wombats (0·7 g) examined in the mountains were approximately double the weight of the control animals from the sea coast (0·6 and 0·4 g, respectively), and the zona glomerulosa represented twice the percentage of total area in kangaroos, but was only 20 per cent greater in mountain wombats (Figs. 1 and 2).

There were striking structural changes in the salivary glands of the alpine animals when compared with the same species living in the sodium rich sea coast areas. Table 4 records the much more extensive duct system of the parotid gland of sodium depleted specimens of *Macropus giganteus* (Shaw) (the grey kangaroo). A similar finding was made in the submandibular glands of the same species where the percentage of total gland represented by the striated ducts was four times that of the

Spring	0·13 (12)	20·6	15·3

replete animals. Measurement of the height of parotid duct cells ($n = 100$) with a micrometer ocular showed that the value for sodium deficient animals was 19·51 ± 3·20μ, and for replete animals, 14·04 ± 3·05μ—($P < 0·01$). The vascular pattern of the sodium deficient animals was considerably different from that usually observed. Blood vessels were extraordinarily abundant around striated ducts. Fig. 3 shows that loops of capillaries penetrate the outer wall of the striated ducts and run in the epithelial zone. The wombat material showed similar changes in the epithelium though not to the same degree.

Table 4. CONSTITUTION OF *Macropus giganteus* (GREY KANGAROO) PAROTID GLAND EXPRESSED IN PERCENTAGE OF TOTAL VOLUME

Condition	Serous cell	Striated duct	Excretory duct
Sodium deficient	86·3	5·3	3·1
Sodium deficient	79·6	12·4	3·6
Sodium deficient	83·2	9·5	4·8
Sodium replete	95·4	0·0	1·5
Sodium replete	94·3	0·3	0·6
Sodium replete	92·7	0·2	1·3

In the parotids of rabbits deficient in sodium the volume of striated ducts was 5·9 per cent of the total volume compared with 1·5 per cent in the replete. The number of mitochondria in these cells was considerably less in the sodium replete animals. The epithelium was approximately twice as high (18·3μ) as in the sodium replete (10·9μ). Striated ducts were present in the submandibular glands whereas they were virtually absent in the sodium replete rabbits. EMG study of the rabbit parotids showed increased density of acinar granules in sodium deficiency. The striated ducts in sodium replete animals (Fig. 4) had low prismatic or cubic cells with very few or no infoldings of the basal cell membrane. Mitochondria were sparsely distributed and separated by cytoplasm. Their cristae were not very closely packed and no intracellular channels were visible. In the sodium deficient animals (Fig. 4), not only were the cells higher but there were profuse infoldings of the basal cell membranes. These infoldings are limiting portions of cell cytoplasm that are packed with mitochondria with very little cytoplasm between them. Furthermore, the cristae of the mitochondria were also very closely arranged suggesting a higher content of cristae per unit volume. The conspicuous intercellular clear channels are suggestive of intercellular channels involved in ion and fluid transport.

The kidneys of the sodium deficient wombats showed hypertrophy of the juxtaglomerular region and much greater height of proximal tubular cells. Changes in the kangaroo kidneys were less marked.

Experiments were undertaken in which groups of softwood sticks impregnated with different inorganic salts were firmly driven into the ground in the region of rabbit warrens. Analysis showed that the impregnation process caused the outer wood to contain up to 1,800 mequiv./kg of sodium whereas the core contained 20 mequiv. The content varied with different salts. Fig. 5 shows that in the spring and early summer in the Snowy Mountains (top three panels) the wild rabbits avidly devoured the pegs impregnated with NaCl and $NaHCO_3$, but largely ignored $MgCl_2$ and distilled water. Some gnawing of sticks impregnated with KCl occurred. In some instances the pegs impregnated with sodium were dug out of the ground and completely eaten. In the late autumn the rabbits did not show significant salt appetite. This corresponded with the urine analyses (mean sodium content, 3 mequiv./l.) zona glomerulosa width (Table 3) and grass analyses (Table 1) including *Stylidium*. Fig. 6 records behavioural observations on peg groups and shows the predominant feeding on pegs with sodium salts. Pegs put out near warrens at Canberra (mean urinary sodium, 18 mequiv./l.) were untouched and so were pegs in the desert area. A fascinating field of future behavioural investigation will centre on the process of initial recognition of the salt sticks by the naive wild depleted rabbits and the specific selection of the sodium containing pegs (Fig. 6). Some instances of intake of magnesium have been seen in pegs left out in the alps for a long time in late summer[9]. This requires further investigation but might be related to the influence of a sustained very high blood

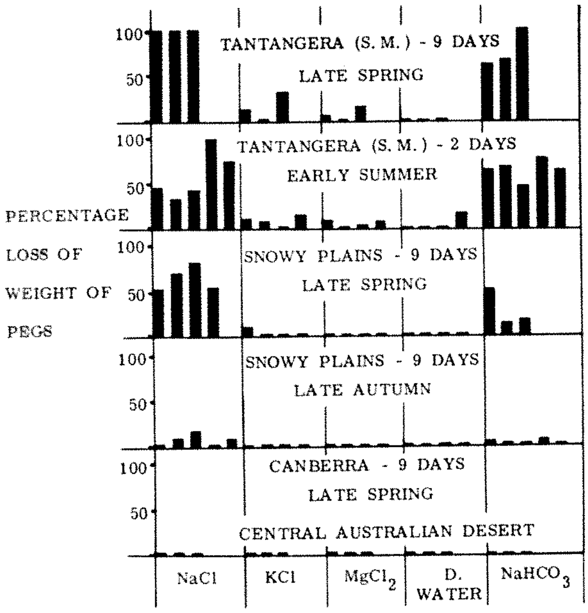

Fig. 5. The percentage loss of weight of soft wooden pegs heavily impregnated with the salts designated when they were placed in the vicinity of rabbit warrens for 9 days. The upper four panels record observations in the alpine region, the bottom panel in the desert and plateau grassland area.

aldosterone in spring and early summer in causing magnesium depletion in the tissue[22].

These studies show that the southern alps of Australia is a region severely deficient in sodium. Rainfall low in sodium together with annual leaching of soil by melting snow contributes to this ecological circumstance[12]. Possibly the most important finding emerging is that severe sodium deficiency does occur in wild animals in nature. In view of the additional stress imposed by the reproductive process, it is evident that a strong selection pressure would operate favouring animals with effective conservatory mechanisms. Similarly, selection would favour animals with central nervous mechanisms such that, when depleted, appetitive drive would cause more extensive exploration of the environment and detection and ingestion of sodium from licks, and plants which accumulate this ion[12]. This statement, as indicated[4], requires qualification in so far as such behaviour under stress of depletion may involve more extensive exposure to predation by carnivores.

The conservatory mechanisms correspond to the physiological responses to sodium deficiency defined in laboratory and clinical conditions[12,14,18]. The function of the renin–angiotensin system in the response to sodium deficiency in the marsupials will be a field for future comparative interest in the light of the preliminary difficulty in obtaining pressor material when incubating kidneys from sodium deficient wombats or kangaroos with sheep substrate.

The morphological changes in the duct system of salivary glands were an important new finding presumably indicative of chronic hyperactivity in active sodium reabsorption. Such structural changes might be attributable to either chronic sodium deficiency and/or the action of aldosterone. Previous observations on the influence of DOCA in producing a great increase in the height of duct epithelium in sheep suggest a hormonal trophic influence. On the question of detrimental effects of sodium deficiency, experiments with wild rabbits (Myers, unpublished) studied in enclosures with thirty-five, fifty or two hundred animals to the acre showed a highly significant reduction of glomerulosa and an increase in fasciculata areas in animals at high density (Table 5). This is consistent with the proposal that density is an additional aggravating stress in sodium deficient zones. In the course of preliminary experiments examining the nodule producing effects of ACTH (Myers and Bults, unpublished) it was found that, of itself, the stress of simple handling of the sodium deficient mountain rabbits resulted in weight loss and morbidity which were not seen in animals from sodium replete regions.

The presence or absence of an appetite for salt in naive wild rabbits was clearly related to sodium balance and physiological reactions of the animals. No controlled observations have been made to date on kangaroos, but

these animals are known to be attracted to salt blocks put out for cattle in the mountain regions. The findings on wild rabbits highlight the problem of the explanation of the biological relevance of the need-free salt appetite exhibited by caged laboratory animals[23]. The latter observation, firmly established in the case of rats, is consistent with Richter's proposition[24] of a genetic ability in mammals to taste salt and that the ability to taste nutritious substances confers survival advantage. Salt taste fibres have been identified in a number of mammalian and more primitive vertebrate species. Bare[25] has suggested that the normal animal is protected against specific food deprivation by this unlearned stimulus response connexion. In this regard it is noteworthy that sodium chloride is a substance likely to be encountered in nature, either solid or in solution. The observations recorded here on various species of wild herbivores in the Rocky Mountains[3,4] indicate, however, a definite seasonal basis in intake, and this is clearly the case with wild rabbits, and is related to the sodium balance. It seems likely that this will also be the case with animals in the Rocky Mountains and Idaho. In the Florey Laboratories, self-selection of solutions of NaCl, $MgCl_2$, $CaCl_2$, KCl has been studied in rabbits captured in the wild when young. Most of these caged animals exhibit only a small need-free intake (sodium in the diet, 60 mequiv./kg) of isotonic or 500 mequiv./l. NaCl solution (mean intake of 0·16 and 0·4 mequiv./day, respectively). It therefore becomes of considerable importance to examine the salt appetite of the many species of the genus *Rattus* which live wild on several continents. Behaviour may depend considerably on the mode of presentation of the substance, and the animal without any metabolic deficiency may accept some isotonic solution but not gnaw wood impregnated with salt. The possibility has to be considered, however, that in natural conditions with a much more diverse range of stimuli engaging the attention of active animals the behaviour does not parallel that seen under the relatively stimulus deprived condition of the laboratory cage[23].

Obviously it is of general biological importance that herbivores are subject to ecological stress in relation to sodium variation, as shown here with the plants of regions varying from below 0·1 to 2,000 mequiv. of sodium/kg of dry weight. The carnivores probably largely avoid sodium deficiency because they feed on herbivores which, though stressed, have nonetheless a high tissue content of sodium. Thus it is unlikely that selection pressures, similar to those with herbivores, operate in carnivores in relation to evolutionary emergence of neural mechanisms evoking salt appetite. In this general context, the situation with regard to omnivores such as man or the rat is particularly interesting. With feral man, as represented by the primitive mountain tribes of New Guinea, dietetic studies have shown that with their essentially vegetarian diet the Highland Papuan consumes 200–400 times more potassium than sodium[26] with sodium intake as low as about 3 mequiv./day. The diet of Papuan communities is often largely dependent on a single staple food—sago, taro, the introduced sweet potato, or more rarely yam or banana. Peripheral whole blood aldosterone levels of Papuans in primitive highland areas have been compared with those in other areas where European food and salt is available. These studies have been done by the Howard Florey Laboratories as part of Macfarlane's extensive metabolic investigations of the peoples of the region. In the former instance, the level of aldosterone was consistent with other evidence of sodium deficiency—that is, mean 25·8 ng/100 ml. ($n = 7$), compared with 9·9 ng/100 ml. ($n = 14$) in the European areas, which is comparable with levels in hospitalized sodium replete patients on a standard diet[17]. The preparation of salt cake and the ancient salt trade in New Guinea Highlands have been described by anthropological investigators[27,28].

A further general consideration emerges from the finding of severe sodium deficiency in herbivores including ruminants in natural conditions. Digestion in the ruminant involves circulation of much larger volumes of alimentary fluid of high sodium content than in other species. The capacity to replace sodium by potassium in this cycle commensurately with sodium deficiency reduces the haemodynamic stress of sodium deficiency and thus is pivotal to adaptation. The data support the hypothesis previously advanced[11,12] that the laboratory demonstration of a large reduction in the ratio of sodium to potassium in the saliva of sodium deficient ruminants mediated by aldosterone reflects a principal mechanism in evolutionary emergence of the capacity of these animals to adapt to stringent environmental conditions.

Discrimination Learning in Animals: an Analysis through Side-effects

by

T. M. BLOOMFIELD

Laboratory of Experimental Psychology,
University of Sussex

Different techniques used in discrimination training of pigeons have different side-effects on the birds. These side-effects of training are important in analysing discrimination learning in animals.

PIGEONS have recently been the subjects of an increasing number of experiments on discrimination learning. The apparatus used in most of these experiments consists of a 1 ft ^{3} sound-attenuated chamber in which a hungry pigeon is placed. Pecks at a 0.75 in diameter disk (response key) on one wall of the chamber can be rewarded by brief access to a grain mixture. If unpredictable rewards (averaging, for example, one per min) follow pecks at the key, the pigeon comes to peck steadily at a rate of between 30 and 90 pecks per min[1]. In experiments on discrimination learning with the pigeon, the desired outcome is that the pigeon should peck to a signal for reward, and not peck to a signal for absence of reward. Three techniques of training have been developed which have this result, but which have different side-effects on the pigeon's behaviour. These by-products of discrimination training are important in analysing what is involved in discriminative behaviour, and they point to the need for revision of the concepts traditionally used in explaining animal discrimination learning[2].

Methods of Discrimination Training

Two training techniques date from earlier studies with rats[3], and can be termed "choice" and "go/no go" methods. In the choice situation, the pigeon is confronted with two illuminated keys in the experimental box. Pecks at one of these (the positive signal, or $S+$) bring occasional, unpredictable rewards, while pecks at the other (the negative signal, or $S-$) are not rewarded. Ultimately the pigeon comes to choose $S+$. In the go/no go method, only one key is present, illuminated with either $S+$ or $S-$. During the positive signal, pecks are rewarded, but during the negative signal, no rewards are forthcoming. A pigeon trained by this procedure pecks to the positive signal, and does not peck to the negative one. In the usual method of training a pigeon on a go/no go discrimination, many pecks are made to the signal for no reward ($S-$) in the first few sessions. Usually, $S+$ and $S-$ are similar, for example, red and green colours, or lines of different angles to the vertical. Recently, however, Terrace[4] has evolved a method of "errorless" training, by which almost all pecks to $S-$ are avoided. The technique consists of presenting the negative signal at first for short durations and at a low intensity of illumination. In these conditions, no pecks are made to it. The duration and intensity of $S-$ are gradually increased to equal those of $S+$. In this way, the discrimination is learned without errors.

Although the end results of the training methods are similar to the extent that the pigeon's behaviour matches the signal, there are differences in other behaviour in the discrimination situation. As the pigeon begins to differentiate the two signals in the go/no go situation, the rate of pecking to $S-$ declines. At the same time, the rate of pecking to $S+$ increases[5]. Pavlov[6] termed a similar effect in salivary conditioning "positive induction", while Reynolds[5] adopted the term "behavioural contrast". When the go/no go discrimination has been acquired with two colours as $S+$ and $S-$, and with many errors, subsequent testing reveals that a new colour is preferred to the original $S+$ colour[7]. This colour is located at a point on the wavelength dimension shifted from $S+$ in a direction away from $S-$. This effect is termed "peak-shift". These phenomena, shown in Fig. 1, occur only after go/no go discrimination learning with errors. Training on a choice discrimination, or on a go/no go discrimination where no errors are made, produces no shift in preference along the continuum, nor an increase in pecking rate to $S+$.

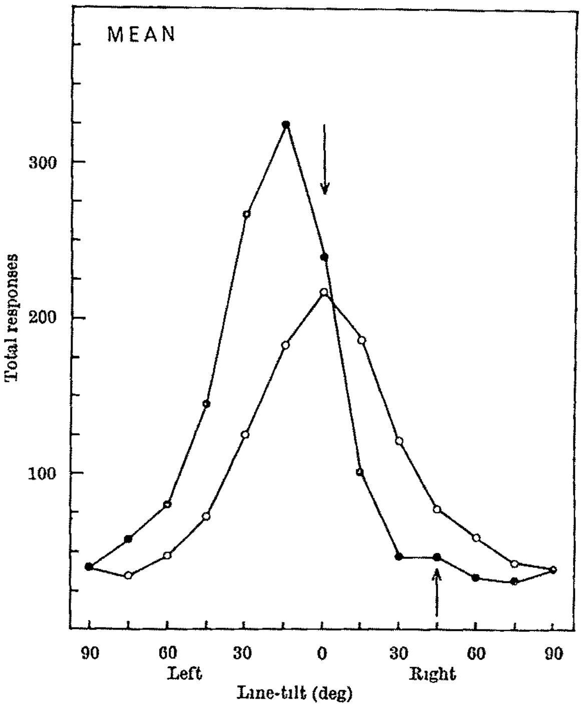

Fig. 1. Total responses during generalization testing of two groups of five pigeons. ●, Results from pigeons trained to discriminate vertical (0°) from 45° in a go/no go situation; ○, results from pigeons trained to discriminate 0° from absence of a line. This training is necessary to ensure attention to the dimension of line-orientation. Pigeons on the 0°/45° discrimination show the peak-shift effect: the maximum point on the gradient is not 0° ($S+$) but 15° left

Two attempts have been made to explain these effects, neither of which is compatible with all the evidence. First, Terrace[8] has suggested that induction or contrast results from a lowered pecking rate to $S-$. There are data, however, to show that a reduced pecking rate is neither necessary[9] nor sufficient[10] for contrast and peak-shift effects. In most studies, frequency of reward is confounded with pecking rate, but where conditions during $S-$ become worse without a lowering of pecking rate (that is, in a schedule where the pigeon must peck slowly to obtain rewards), it is change in reward frequency, not in pecking rate, that correlates with contrast effects. A recent experiment (T. M. Bloomfield, unpublished) shows that contrast is linked to an increased evaluation of reward by the animal, a pigeon will choose the reward given for pecks to $S+$ in a discrimination, in preference to one given outside the discrimination situation. Once again, this result is restricted to the go/no go situation where errors occur in training, and throws doubt on the second line taken to explain contrast and peak-shift.

This is the "adaptation-level" theory of Helson[11], which suggests that rewards (among other events) are assessed against the context of rewards the animal has experienced. A moderate reward, according to this theory, will seem large in a context of small rewards and small in a context of large rewards. As it stands, however, this account is of little use in differentiating between discrimination learning with and without errors. In both cases, the pigeon has been exposed to a certain frequency of reward during the initial training with $S+$. Later, no rewards are available for pecks to the $S-$, and the theory of adaptation-level predicts the reward available in $S+$ will increase in value. Clearly, the effects of absence of reward in $S-$ could depend on prior response to $S-$, which is absent in errorless learning. To answer this point it would be necessary, however, to take the discussion away from adaptation-levels into questions of similarity of, and thus into classification of, the positive and negative signals. These questions are raised later.

Rules governing Discrimination Performance

In attempts to explain the side-effects of discrimination acquisition, it was assumed that they were awkward phenomena to be explained away. It has been too often taken for granted[2] that discrimination learning is simply a matter of a response being attached to one "stimulus" and eliminated in the presence of another. It might be more profitable, however, to use these effects in the analysis of discrimination learning itself, by asking whether such behaviour reveals anything about what the animal has learned as a result of discrimination training. One rule that could obviously govern behaviour following go/no go discrimination acquisition would be: peck at $S+$, don't peck at $S-$. A rule with a "don't" in it is equivalent to inhibition of behaviour—the pigeon suppresses pecking during $S-$. Pavlov[6] has listed some methods of checking for inhibition involved in a negative rule, one of which is relevant here. If pecking during $S-$ is inhibited or suppressed, it should be possible to recover it. In fact, inducing extra stress in rats by electric shock[12], and administering "tranquillizing" drugs to pigeons[13], both increase responding during $S-$ in a go/no go discrimination learned with errors. The latter effect does not appear after errorless discrimination learning.

Other evidence[7] shows that a choice discrimination does not transfer to a go/no go situation with the same signals. The fact that a pigeon has learned to choose one signal in preference to another does not mean that it has learned to inhibit pecking when $S-$ alone is present. Choice discriminations thus seem explicable in terms of the single rule: peck to $S+$. Go/no go discriminations, on the other hand, involve the use of two rules, as explained. The fact that errorless go/no go discriminations are not susceptible to disinhibitory procedures suggests that these, too, come under the single rule: peck to $S+$. Such an analysis is supported by the restriction of contrast and peak-shift effects to go/no go discriminations learned with errors—the one discrimination situation that seems to require a negative rule to govern the pigeon's behaviour. The reward for pecks to $S+$ is overvalued only where the pigeon is inhibiting pecks to $S-$.

Classification of Discriminative Signals

This analysis, however, does not make clear the processes involved in errorless learning. Why is there no inhibition of pecking during $S-$, so that a negative rule seems not to be necessary? Closer inspection reveals the rules set out here to be ambiguous with regard to signal classification. It is clear from work with rats[14] that stimuli are classified by animals along certain dimensions only. The use of the term "$S-$" in these rules leaves open what is the negative signal for the animal—how the negative signal is classified. In all cases of discrimination learning, it has been shown that pecking rate systematically changes as the $S+$ is shifted along the dimension involved in discrimination training. For example, a pigeon performing discriminatively with respect to red as $S+$ and green as $S-$ will show a decline in rate of pecking as the wavelength shifts from red either towards or away from green. It is clear therefore that pecking was occurring with respect to red on the colour dimension. Tests with $S-$, however, reveal differences between training methods. If a discrimination is learned between a red circle ($S+$) and a white vertical line ($S-$) with errors in a go/no go situation, it has been shown that variations in line-angle from the vertical cause increase in pecking, although these variations do not bring the line any closer to the red circle[15]. Thus it seems clear that the $S-$ in the negative rule means the quite specific signal used by the experimenter.

After errorless learning, this effect does not occur. Variations in $S-$ do not alter pecking rate, which remains zero. This is possible only if identification of the $S-$ is made on the basis of absence of $S+$. If the $S-$ is identified in its own right, the pigeon's behaviour will change when $S-$ is changed, as it does after go/no go discrimination learning with errors.

It seems therefore that it is possible to analyse discrimination performance in pigeons according to the nature of the rules governing their behaviour and according to the way in which $S-$ is identified or classified. It is important to separate these two aspects of discrimination situations. An earlier attempt by Jenkins[16] to set out rules governing the pigeon's behaviour was vitiated by a confusion between the rules themselves and the way in which the positive and negative signals were classified. The side-effects of training turn out to be the product of formation of a negative rule, a finding obscured by Jenkins' rules, which all contained negative parts. Forming a negative rule is clearly a difficult process for the pigeon, shown by emotional behaviour during $S-$. Through attention to all aspects of behaviour in these discrimination situations, it is possible to improve our understanding of the behaviour of animals that undergo the various kinds of discrimination training. Such analysis has ideally both conceptual and empirical value. It can clarify our concept of discrimination and provide us, at the same time, with more information about the handling of discrimination problems by animals.

LETTERS TO THE EDITOR

ASTRONOMY

Are the Optical Luminosity Fluctuations of 3C 273 Random ?

WE have shown[1] that a light curve similar to that of the quasi-stellar source *3C* 273 can be generated by a superposition of unit light curves occurring at random times Gudzenko, Ozernoy and Chertoprud[2] have argued (1) that the distribution of the observed luminosities should be expected to be Gaussian on our model, and (2) that the observed distribution is not Gaussian, so that the luminosity curve cannot be regarded as the superposition of random events The purpose of this communication is to question the validity of both arguments and to show that the luminosity record may still be considered to be of random origin

Regarding the first argument, the probability distribution of a shot noise process will not usually be Gaussian, only in the limit when the number of pulses per unit time approaches infinity is the probability distribution rigorously Gaussian[5] In our model, the ratio of the number of pulses per unit time to their "time constant" is about 40, so that it is difficult to say to what extent the distribution on our model should be expected to be Gaussian Furthermore, it should be noted that, if a random variable has a Gaussian distribution, a function of s usually does not Specifically, $\log(s)$, or the astronomical magnitude of s would not have a Gaussian probability distribution

Regarding the second argument, if the observed luminosity is written as

$$\begin{aligned} I(t) &= x(t)\cos 2\pi f_0 t + y(t)\sin 2\pi f_0 t \\ &= \sqrt{x^2(t)+y^2(t)}\,(\cos 2\pi f_0 t + \tan^{-1} x(t)/y(t)) \\ &= R(t)\cos(2\pi f_0 t + \theta(t)) \end{aligned}$$

then, if $x(t)$ and $y(t)$ are independent Gaussian processes so that $I(t)$ is Gaussian, $R(t)$ is a Rayleigh distribution[3] It was argued that the hypothesis of Rayleigh distribution for R calculated from the data may be rejected with 99 per cent confidence and hence that $I(t)$ is not Gaussian distributed

For $R(t)$ to be Rayleigh distributed, it is crucial that $x(t)$ and $y(t)$ be Gaussian and independent The $x(t)$ and $y(t)$ are calculated from the observational record by forming trigonometric sums the coefficients of which are weighted time averages of the observed $I(t)$ Demonstration of the independence of $x(t)$ and $y(t)$ requires that the time over which the averages are made is very large In the case of *3C* 273, if the dominant frequency of about 0 10 yr^{-1} is taken for f_0, the total observation time is only about seven times the supposed periodicity and it seems questionable whether this can ensure the independence of $x(t)$ and $y(t)$

Probably the most straightforward way of testing the Gaussian hypothesis is to apply the χ^2 test[4] We have done this with both the actual luminosity curve and our simulation In the case of the luminosity data, the original photometer data in magnitudes were converted to intensities The samples used in the test must be independent, and so the luminosity curve samples must be separated by an interval of the order of the correlation time which for our simulation is about 1 year Hence for 73 years of observations seventy-three samples were taken The calculated ("observed") value of χ_ν^2, $\hat{\chi}_\nu^2$, and the probability that χ_ν^2 exceeds $\hat{\chi}_\nu^2$, $P(\chi^2 > \hat{\chi}_\nu^2)$, are shown in Table 1 We see that the Gaussian hypothesis for *3C* 273 may be accepted at a 7 per cent confidence level, which is about the same level as that for the simulation which was constructed by a random process We conclude that the observed luminosity record may still be regarded as the result of a high density random process

Table 1 APPLICATION OF THE χ_ν^2 TEST TO THE GAUSSIAN HYPOTHESIS

	ν (degrees of freedom)	$\hat{\chi}_\nu^2$	$P(\chi_\nu^2 > \hat{\chi}_\nu^2)$
3C 273	7	12 9	7 per cent
Simulation	7	14 0	5 per cent

Stimulated Inverse Compton Scattering in Radio Sources

OSTER[1] has claimed that energy losses due to the inverse Compton effect can be considerably larger than was previously thought, when stimulated scattering is taken into account If true, this would seriously hinder the understanding of compact radio sources We wish to point out that Oster's discussion is erroneous and grossly exaggerates the importance of stimulated inverse Compton scattering

We first consider the scattering of radiation by an electron at rest, neglecting recoil The radiation field is described by $N(\varepsilon, \theta, \varphi)$ photons per unit volume, per unit energy interval, per unit solid angle, θ and φ being polar co-ordinates centred on the electron We are neglecting recoil, and so the photon energy is not changed by scattering The rate at which photons of energy ε incident from a small element of solid angle $d\Omega(\theta,\varphi)$ are scattered into an element $d\Omega'(\theta', \varphi')$ is given by

$$c\sigma(\gamma)\,N(\varepsilon, \theta, \varphi)\,[1 + \frac{hc^3}{8\pi\varepsilon^2} N(\varepsilon, \theta', \varphi')]\,d\Omega d\Omega'$$

where χ is the angle between the directions of the incoming and outgoing photons, and $\sigma(\chi)$ is the differential cross-section The second term in the brackets is the number of photons per unit volume of phase space (occupation number), and gives the contribution of stimulated scattering Similarly, the reverse rate is given by

$$c\sigma(\chi)\,N(\varepsilon, \theta', \varphi')\,[1 + \frac{hc^3}{8\pi\varepsilon^2} N(\varepsilon, \theta, \varphi)]\,d\Omega d\Omega'$$

We observe that the net contribution from stimulated scattering is zero

Oster considered the case of relativistic electrons, with Lorentz factor γ, moving through an isotropic radiation field In the rest frame of an electron, the radiation field then consists of an intense beam of angular spread $\sim\gamma^{-1}$ and a weak component from all other directions This argument, which applies to an arbitrary angular distribution of radiation, shows that the stimulated term has no net effect Oster obtained a large contribution from stimulated scattering (even though he neglected recoil) because he included scattering out of the beam, but neglected scattering back into it. The latter represents events where, in the source frame, the electron gains energy from the photon. Although spontaneous scatterings of this type are indeed negligible, the corresponding stimulated scatterings are important because of the high occupation number in the beam, and do in fact cancel the term obtained by Oster.

A more complete analysis, which allows for recoil, shows that stimulated scattering does contribute to the loss rate of relativistic electrons. The relevant formalism is given by Dreicer[2]. The contribution is $\sim \varepsilon/\gamma mc^2$ times smaller than Oster's estimate, however, where ε is the final energy of the relevant photons in the frame of the source. In Oster's example, where $\gamma \sim 100$ and the important frequency range is $\lesssim 10^{11}$ Hz, this factor is $\lesssim 10^{-11}$. Furthermore, for reasonable photon and electron spectra the effect has the opposite sign, and tends to reduce the loss rate.

Stimulated scattering could be important only if the brightness temperature of the radiation field greatly exceeded the kinetic temperature of the relativistic electrons. This is not the case in any of the quasar models referred to by Oster.

Profiles of the Unidentified Interstellar Absorption Bands at 4890 Å and 4760 Å at Different Galactic Longitudes

OF the four known diffuse interstellar absorption bands, those at 4430 Å and 6180 Å have already[1,2] had profiles of high photometric accuracy assigned to them, and it has been shown that these profiles are the same over three regions of galactic longitude. A similar analysis is made here for the two known remaining bands at 4890 Å and 4760 Å.

The first of these two bands was discovered independently by Wilson[3] and Butler and Seddon[4], while the second was tentatively identified as interstellar by Merrill, in private correspondence with Beals[5]. Little has been attempted in the investigation of these features because of their weakness and width. The band at 4890 Å is particularly difficult to investigate because it overlaps the stellar lines of Hβ at 4861 Å and HeI at 4922 Å, both of which are strong in the spectra of most stars sufficiently bright and distant to show significant band absorption. The spectrophotometry of early type stars carried out at this observatory[4] assumed the region of this band to be a continuum, until sufficient data were acquired to show this assumption to be untenable. Wilson has published in this series[6] a spectrophotometric atlas of *B*1 stars, in which the distortion of the continuum following on this assumption can be seen. The effect of neglecting the band is to give the appearance of asymmetrical and wide emission to the Hβ profile.

In this investigation, the same collection of data has been used as before[1,2], so that the results may be strictly comparable. There are fifteen supergiant stars of types ranging from *B*2 to *A*0, divided into three groups by galactic longitude. The ranges of longitude are group 1 (Cygnus), $020° < l^{II} < 120°$, group 2 (Perseus), $120° < l^{II} < 145°$, group 3 (Auriga-Gemini), $145° < l^{II} < 190°$. For convenience, the stars used are detailed in Table 1, this table being based on that in ref. 1, with the addition for some of the stars of the β-index of Crawford, and of some individual measures of 4890 and 6180 in the present list of stars, taken from the *Publications* of this observatory. The spectrophotometric measures in each of these three groups have been averaged as before. This process reduces the stellar contribution because of the range of types, and increases the signal-to-noise ratio of the general continuum and the interstellar features.

The measures are shown in Fig 1. It has not been considered worth while to show the individual traces for the three regions. The bottom two traces, labelled m_1-m_2 and m_1-m_3, show the differences between the Cygnus and Perseus regions, and between Cygnus and Auriga-Gemini, the ordinates being to the same scale as the trace "SUM".

The general smooth curvature in the traces is a result of differences in photographic emulsions, as mentioned in the communication on the band at 6180 Å, it will not affect the conclusions reached here. The top trace is of the average of all fifteen stars, again showing some general curvature, which has been eliminated in the trace labelled "SUM". There is an obvious band at 4890 Å. The same cannot be said for the band at 4760 Å, which if present at all is little different from the general noise level.

In the earlier communications, it was shown that the bands at 4430 Å and 6180 Å were completely cancelled out by the differencing process. This reflects a purely fortuitous grouping effect in the original selection of the stars, the grouping depending to a large extent on the use of the 36 in reflector at its limit. The same cancellation has taken place here in the difference m_1-m_3, showing that the profiles in these two regions are equal in size and shape. The other difference, however, shows some sign of an inequality in size. To be more sure of this, all measured points outside the apparent profiles of 4890 Å and that presumed for 4760 Å were averaged in groups of ten, and a least mean squares curve of second degree fitted to these groups. These are the inserted square points. The absorption due to the 4890 Å band is apparently greater in the direction of Perseus than in that of either Cygnus or Auriga-Gemini, and the same

* No allowance made for stellar blends

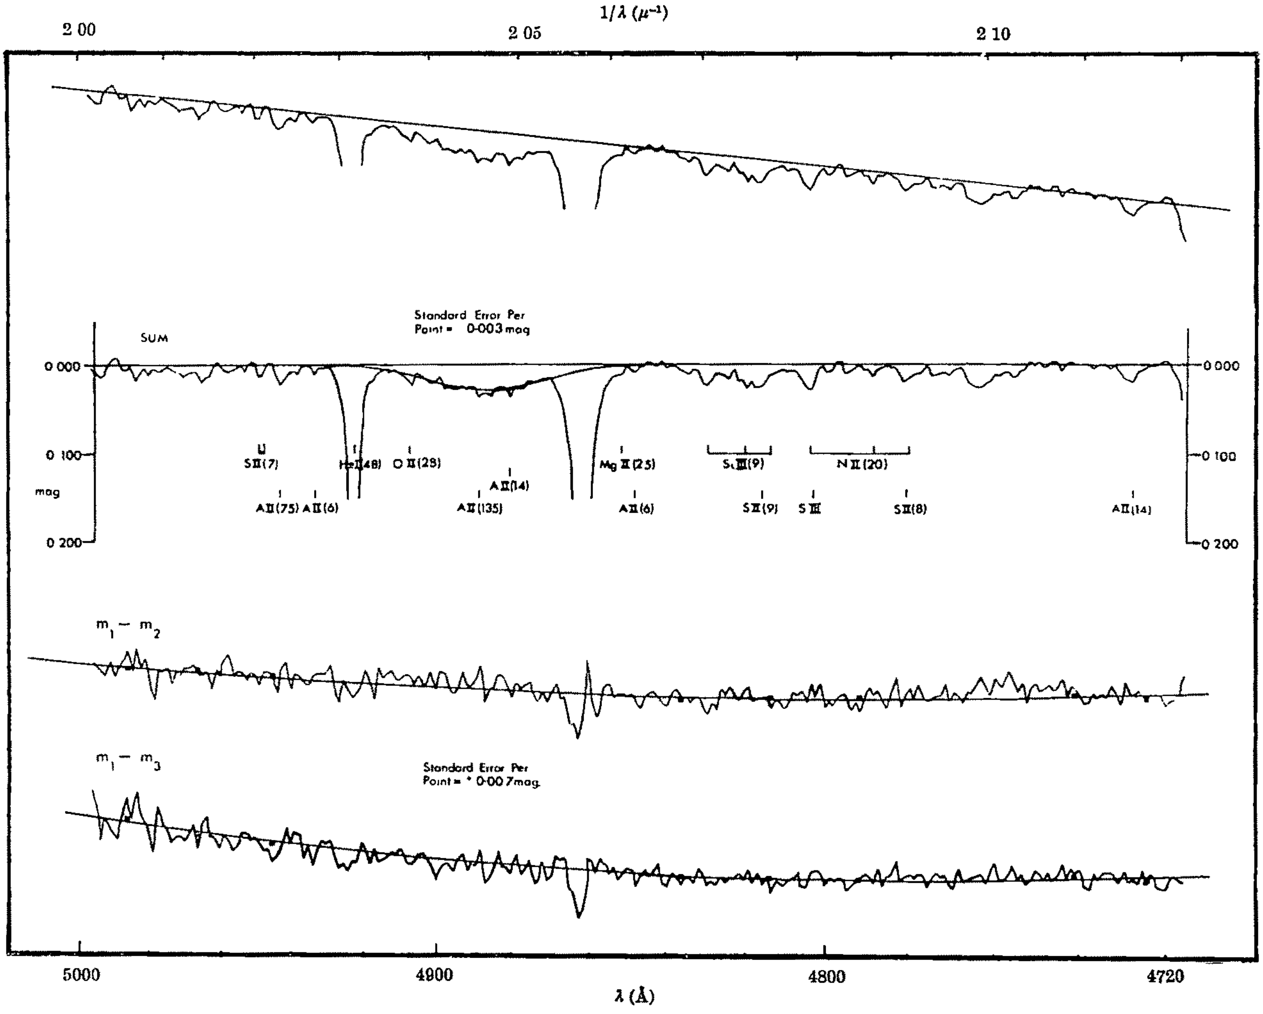

Fig 1 Mean spectrophotometric measures using the stars listed in Table 1

is probably true of the feature at 4760 Å This behaviour is different from that of 4430 Å and 6180 Å, where profile shapes and sizes were the same in all three areas

This difference in the profiles does not indicate any difference in shape, it therefore seems permissible to average all three groups to produce the "SUM" profile Both wings of the 4890 band are obscured, by Hβ on one side and 4922 HeI on the other In the band itself there are some small fluctuations of which the larger are probably real and stellar in origin The individual independent measured points were then averaged in groups of three throughout the possible extent of 4890, omitting only the two strong features and the peaks of the larger, probably real fluctuations These average points are shown in Fig 2 The dotted curve inserted through these points is a simple Gaussian, fitted by least mean squares It is emphasized that a Gaussian curve has been chosen for simplicity, the errors do not justify any elaboration here Nevertheless, the fit is seen to be good, and from the fitting process the centre of 4890 can be given as 4886 6 Å ± 0 9 Å, its half width as 34 9 Å ± 0 8 Å and the equivalent width for this mean group of fifteen stars is 1·08 eÅ. The real error in the last figure is difficult to estimate, but is of the order of ± 0 03 eÅ

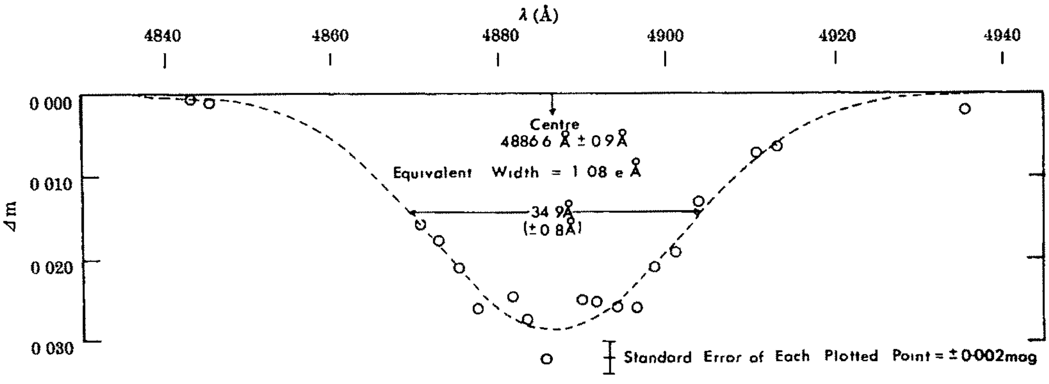

Fig 2 Averaged points throughout the possible extent of the 4890 band

These three parameters are given in Table 2 for each of the diffuse interstellar bands The equivalent widths of 4890 and 6180 are equal and are about half that of 4430 Whereas, however, the half widths of 4430 and 6180 are in the same ratio as their central wavelengths, this does not hold for 4890, which as we have already seen does not have the same profile, nor apparently is it invariant with galactic longitude

Table 2

Nominal wavelength	Central wavelength (Å)	Half width (Å)	Equivalent width (eÅ)
4430	4429 5	21 2	2 18
4890	4886 6	34 9	1 08
6180	6175	29	1 03

Table 1 shows the collected values of equivalent widths of the interstellar bands as found[4,7,8] in the spectrophotometric investigation of early-type stars If a least mean squares fit of these values of strength of 4430 against 6180 and 4890 is made, the two constants of proportionality are found to be 0 68 and 0 52, respectively The former we have seen[2] is to be reduced by a factor of 0 79 to eliminate the contribution of the diffuse line 6203 it then becomes 0 54 The coefficient of correlation in both cases is 0 72 The strengths of 4890 and 6180 are seen by this independent reduction to be equal to each other and to approximately half that of 4430

If it occurs at all, the reported band at 4760 Å is very much smaller than that at 4890 Å There is an indication of a narrower feature at 4760 Å in the mean plot, and a possible band in the Perseus direction that is not present in the Cygnus and Auriga-Gemini regions, but in any case these are too small here to justify further investigation If the reported band at 4760 Å has approximately the same profile as 4890, it is weaker by a factor of 5 at least

The presence of the 4890 absorption band has a small effect on the β-measures of Crawford[9] The whole of the 4890 band is included in his 150 Å broad reference, while his narrow band filters respond to part of the profile. The net result of neglect of the 4890 absorption will be that assigned β values will be too high and this difference will increase with increasing colour excess The size of the difference will depend on the profile of the narrow-band filter, indeed, it will go through zero at a filter half-width of something less than 15 Å, if the filter is centred on Hβ Lack of information about the filters makes it impossible to say with any accuracy how badly the β-index will be affected As a rough estimate, however, the effect will exceed the quoted error of 0 007 for $E_{B-V} = 1\ 0$ in the 30 Å filter case This corresponds to more than 5 per cent of the range of β for any one spectral type

Some evidence has been found[10] that when spectra with heavy 4430 absorption are differenced from others of the same spectral type with small absorption, the residual 4430 profile is slightly asymmetrical, with a steeper slope on the red wing than the blue Because, however, the band considered here at 4890 and that at 6180 are of small equivalent width and greater half-width than 4430, any such asymmetry that might be present in them is not detectable here More accurate photoelectric measures, with averaging and differencing techniques, will be needed for all three bands

Spectral Absorption of Excited Molecules in Iron Aerosols

THE existence of interstellar absorption bands of unknown origin has drawn our attention to absorption by finely dispersed aerosols of solids We have in particular investigated iron aerosols obtained by thermal decomposition of $Fe(CO)_5$ at concentrations of less than ten parts per million in various carrier gases The iron particles resulting from this treatment were between 30 and 200 Å in size These yield an absorption curve which, between 3500 and 6000 Å, agrees well with the theory developed by Mie if the optical constants of bulk iron and the real size of the particles were taken into account With a particular size distribution of the particles the absorption was found to be inversely proportional to the wavelength, as observed in interstellar absorption

Superimposed on this absorption were bands with half-widths between 20 and 100 Å which varied with the carrier gas but which were not found in the absence of iron particles With argon as the carrier gas, the positions of these bands coincided with the Herzberg and Ångstrom bands for carbon monoxide, but, within the range of accuracy, the bands may also be interpreted as triplet transitions because the (0–0)-transition of $d^3\Pi \rightarrow b^3\Sigma^+$ differs from the corresponding transition of the Ångstrom system by less than 25 Å. Evidence which supports the second possibility is provided by the fact that when large amounts of nitrogen are added to the argon carrier gas, the bands of the second positive group of nitrogen were observed together with the Goldstein–Kaplan bands In addition, bands of the green system have been found Although the absorption is small ($k < 10^{-6}$ cm^{-1}), observations are reproducible with an absorption length of 100 m because no strong absorption bands from the ground state of the nitrogen or carbon monoxide molecules are present in the spectral range investigated

The lower states of the observed absorption bands are all attributable to energy levels of 7–9 eV, which implies that the excitation cannot be due either to chemical reactions or to incident photons only In our view, the bands are due to molecules which are adsorbed on the surfaces of the iron particles The excitation might be caused by the large surface energy of the small particles When small particles are combining or surface crystallites are relocated, large amounts of energy may be set free which could be transferred to single gas molecules adsorbed on the surfaces In this way, certain high energy levels can be populated in a manner which differs from that involved in thermal equilibrium Support for this view is provided by the disappearance of the carbon monoxide bands as nitrogen concentration in the carrier gas is increased It must be assumed that the large free enthalpy of adsorption of carbon monoxide on iron particles is outweighed by the large number of the nitrogen molecules which reach the surface

With pure photochemical decomposition of $Fe(CO)_5$ in the same conditions, only the carbon monoxide bands and the well known absorption edge towards the ultraviolet have been found Independently of the carrier gas used, the carbon monoxide bands show up particularly well The aerosol particles obtained in this way were crystallites of iron with a mean diameter of about 10 Å and large flakes of the well known decomposition product $Fe_2(CO)_9$ The strength of the carbon monoxide bands could be explained by the fact that this decomposition produces an especially high concentration of carbon monoxide near the surfaces of the particles

We are at present investigating the excitation associated with particles with a large heat of sublimation—carbon, for example—and are also looking for excitation of metastable states using various carrier gases

PLANETARY SCIENCE

Electrodynamic Effects of Jupiter's Satellite Io

Jupiter's satellite Io has remarkable control of Jovian decametric radio emission (recently reviewed[1,2]) and also a very high and possibly varying albedo[3,4]

Io's orbit is approximately 6 R_J (Jovian radii), while the magnetosphere itself probably extends[5] beyond 50 R_J The radiation belt responsible for the decametric radio synchrotron emission extends[6] to about 6 R_J so that Io moves deep in the magnetosphere near the belt boundary The magnetosphere rotates with the planet, causing Io to move westwards through the magnetosphere at a speed of about 56 km $\sec^{-1}$ This motion may cause an electromagnetic disturbance which contributes to the radio emission On the other hand, tidal control by Io seems unlikely in view of the absence of any control by the other satellites

The possible form of the electromagnetic disturbance has been discussed by a number of workers Warwick[1] concluded that the disturbance would be minor, while Ellis[7] mentioned the possible importance of the low-velocity hydromagnetic mode There seems little likelihood of a long fan-shaped proboscis[8] or of the direct stimulation of plasma waves[9], because of the gravitational potential barrier[10]

If the satellite's electrical conductivity were very small then it would cause only a minor hydromagnetic disturbance, as does the Moon in its motion through the interplanetary medium (unpublished work of N F Ness, K W Behannon, C S Scearce and S C Canterano)

Irrespective of Io's electrical conductivity, long immersion of the satellite in the steady magnetospheric field must ensure its magnetization The alternative requires a system of electric currents flowing on its surface, driven by an electric field E given by Maxwell's equation $\nabla \times E = -\partial B/\partial t$ and this requires a flow of field lines into Io The only way to provide E continually, and so to demagnetize Io permanently, is to rotate it about an axis perpendicular to the undisturbed field In the absence of such rotation Io's magnetic field strength is 0 05 gauss[1] and flux about 4×10^{15} gauss cm^2

If Io is magnetized and is conducting, then its relative motion through the magnetosphere (V) will have drastic results Field lines passing through Io cannot follow the motion of the external plasma because this would induce excessive electric field $V \times B$ and excessive current in the satellite and in the plasma Sufficient current (j) flows to deform the external field and to provide a force $j \times B$ which slows down the plasma, the field deformation then propagates away The situation is shown in Fig 1a, plasma and field are compressed at the left and diffuse into Io, while field lines diffuse out at the right The effectiveness of Io in creating a disturbance depends on its conductivity σ according to the well known relationship $t_0 \sim \sigma l^2$, where t_0 and l are characteristic time and dimension Putting $l = 3\ 2 \times 10^8$ cm (Io's diameter) and t_0 equal to this distance divided by the relative speed (about 57 s) we find the required conductivity (emu) $\gtrsim 6 \times 10^{-16}$

If the ratio of the velocity V to the hydromagnetic velocity V_A is large, then the disturbance travels "down wind" to provide a magnetotail as for the Earth If the ratio is small, then most of the disturbance travels as hydromagnetic twist or shear waves along the field lines The velocity V_A near Io is probably in the range 10^3–10^4 km $\sec^{-1}$ (refs 1 and 7), and so is much larger than V and far from shock conditions There is little magnetic perturbation in Jupiter's equatorial plane and the main effect is that the whole magnetic force tube frozen into Io (4×10^{15} gauss cm^2) moves bodily with Io as in Fig 1b which shows a meridian plane in Jupiter's magnetosphere and Io's force tube (IFT) The relative motion of Io is out from the plane of the paper, and if we regard the force tube as being rigid then it moves as a whole, executing 'interchange motions" with surrounding force tubes These motions resemble the motions discussed in connexion with the Earth's magnetosphere[11], except for the driving force The whole of IFT moves about the axis of rotation, more or less in meridian planes with the centre passing through Io and the ends dipping into the iono-

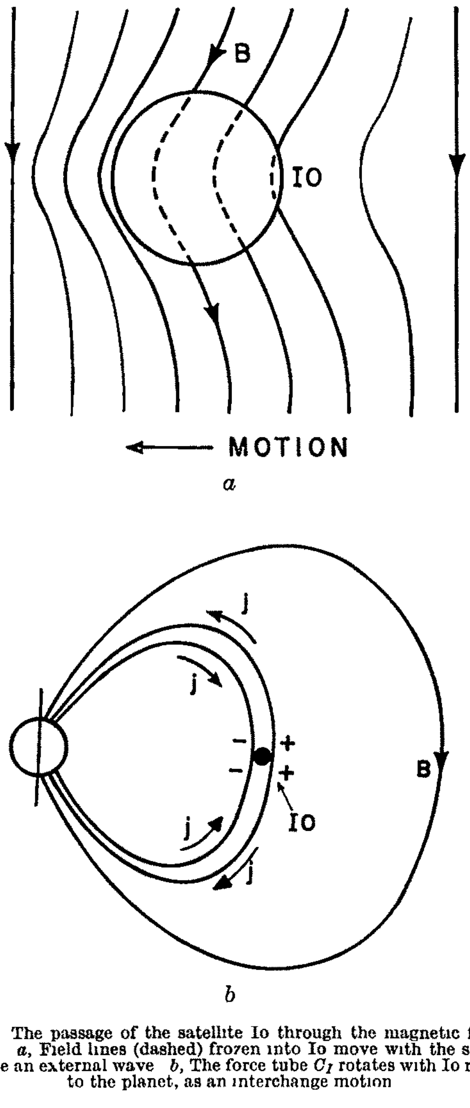

Fig 1 The passage of the satellite Io through the magnetic field of Jupiter a, Field lines (dashed) frozen into Io move with the satellite to create an external wave b, The force tube C_I rotates with Io relative to the planet, as an interchange motion

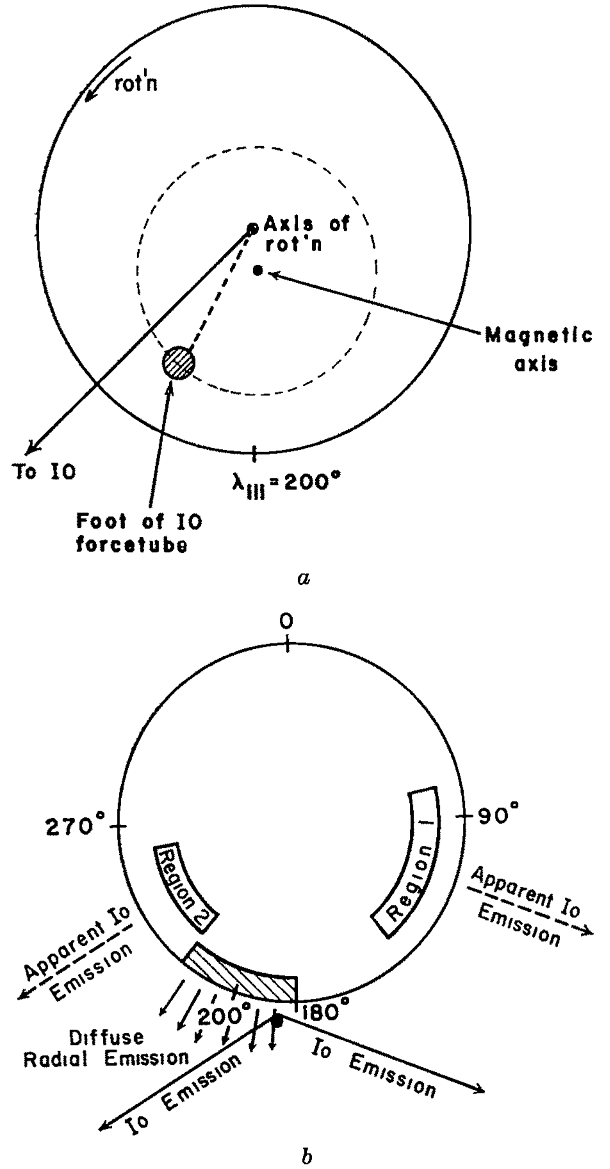

Fig 2 Two plots of Jupiter in Longitude System III *a*, The high latitude ionosphere showing the rotational and magnetic axes and the path (dashed line) of the foot of Io's force tube *b*, A schematic representation of the apparent emission regions of decametric radio bursts and the manner in which most emission may originate from one region

sphere near latitudes 65° N and S The foot of IFT in the northern hemisphere moves around the north magnetic north pole (Fig 2*a*) and, because of the 10° tilt of the magnetic to the rotational axis, excentrically around the latter

Relative motion V creates electric polarization as shown in Fig 1*b*, electrons from the plasma flow to neutralize the positive charge and ions to neutralize the negative charge (because Io cannot emit electrons) Currents (j) flow up and down the sides of IFT and hydromagnetic waves propagate to the ionosphere in each hemisphere, or lower if the lower atmosphere is conducting For maximum effect, Io's electrical conductivity must be such that time $t_0 \sim \sigma l^2$ exceeds the time for the wave to propagate to the ionosphere The velocity of the wave is not evident, but cannot exceed that of the fast mode, which is the Alfvén velocity[12] Elements of the slow hydromagnetic mode, however, can also be present and we will for the present assume a velocity of propagation along IFT of 500 km s^{-1} The disturbance reaches the ionosphere (in each hemisphere) in about 20 min and the required conductivity of Io is about 10^{-14} emu

If Io's conductivity exceeds this value, then its whole force tube, extending from ionosphere to ionosphere, will swing westward relative to the magnetosphere The cross-sectional area of the force tube perpendicular to the direction of motion is about 200 times that of Io and the disturbance correspondingly large, leaving a wake of turbulence and fast particles extending eastward from IFT The bending of the force tube means that the feet are displaced eastward of Io, the time delay of 20 min corresponding to a longitude difference of about 10 degrees Thus any Io related electromagnetic phenomena should be found at longitudes between 0° and ~10° or more eastward of Io

IFT dips into both N and S ionospheres and rotates around the two poles (rotational and magnetic) as shown in Fig 2*a* The horizontal dimensions of the feet are about 150 km and the speed through the ionosphere is about 5 km s^{-1} Collisions between ions carried by the force tube and stationary neutral atoms will heat the ionosphere to a temperature exceeding 1,000° K, considerably above the undisturbed value of about 200° K[13] The tube motion is also likely to cause a shock wave outside the tube and to generate an extensive disturbance

Decametric radio emission from Jupiter is associated with several System III longitude regions and is controlled to a considerable extent by the position of Io in its orbit There is yet no general agreement as to the locations of these regions and positions, but an approximate picture is given in Fig 2*b* Emission probability is highest when the longitude of Io approximates that of the north magnetic pole ($\lambda_{III} \sim 200°$) The sectors marked 1 and 2 and the hatched sector are "apparent" regions of emission in the sense that stronger signals are received during their central meridian passages seen from the Earth[1,2] For none of these regions, however, need we assume that emission is radially away from the centre of the planet, and so there is great flexibility in the interpretation of the data

When Io is at $\lambda_{III} = 200°$ its wake and ionospheric disturbance lie eastward, let us suppose at $\lambda_{III} = 185°$ Radio emission from this region (shown by a large dot) need not be wholly radial and we will assume that some is emitted in two beams directed at about 75° away from the meridian plane of the disturbance Emission which seems to come from regions 1 and 2 is now explained in terms of radiation from Io's disturbance region[14], and does not meet the chief difficulty of having to explain Io's control exercised from a distant part of the magnetosphere[7] The radiation from the hatched sector is presumably in meridian planes and may have a different source mechanism

We speculate that Io's force tube disturbance, either in the ionosphere or magnetosphere, may have the form of a bow wave directed westward Radio emission from the wave front, in both the forward and reverse directions, might be expected, as for type II solar radio bursts[15] If either the beaming or generation processes have increased efficiency at lower rotational latitudes, this would account for enhanced emission near the magnetic pole as may be seen from Fig. 2*a* Lack of influence of the other Jovian satellites on the decametric emission may be caused by a lack of adequate electrical conductivity or by rotation about an axis perpendicular to Jupiter's axis

The motion of IFT may also account for Jupiter's radiation belt The electric potential across IFT is about 10^5 V, and particles accelerated there and drifting inwards under the influence of the complex electromagnetic field[5] will be further accelerated The violent ionospheric disturbance will spread plasma through the magnetic shell traversed by Io as well as providing magnetic disturbances and auroras near latitude 66° The centrifugal force on plasma near the equatorial plane will create a Jovian ring current and lead to interchange motions Finally, the incidence of plasma on the surface of Io may account for its unusual optical properties[3,4]

Detection of a Deep Boundary Current in the Western South Pacific

FROM the distribution of salinity, temperature, oxygen and radio-carbon observed in the deep oceans (deeper than 2,000 m) of the world, it seems that all the deep water in both the North and South Pacific comes from other oceans, entering the Pacific from the south The Tasman Sea is closed to the north at depths greater than 3,000 m, so that any deep current reaching into the North Pacific must lie east of New Zealand The simple linear geostrophic theory of the abyssal circulation proposed by Stommel and Arons[1,2] requires that the source water, "after passing south of New Zealand, flows northward into the Pacific Ocean as a narrow western boundary current along the Tonga–Kermadec Trench". It seems surprising that the source water should move in such a narrow current when it has the full width of the South Pacific within which it might flow, but the dynamics demands weak, southward geostrophic flow over most of the width of the South Pacific, and permits northward flow only in a higher-order boundary current We are not at all certain that such simple dynamics do prevail, and the data have so far been insufficient to reveal the existence or non-existence of this current

Between March 10 and August 2, 1967, we made two long oceanographic sections (Scorpio Expedition) across the South Pacific between Australia and Chile on 43° 15′ S and 28° 15′ S , with 78 and 100 hydrographic stations, respectively In the deep water, temperatures were measured with Kahl reversing thermometers of range − 2° to 60° C on which temperature could be read to ± 0 001° C Salinities were measured on a University of Washington conductivity bridge ('Paquette' model) with precision ± 0 002‰ The work was done aboard the USNS Eltanin, the research vessel of the US Antarctic Research Program

The sections were made partly to fill a great void in the world coverage of oceanographic data, and partly in the belief that with closely spaced, highly precise observations, features not discernible in the sparse older data[3] would be disclosed Chief among these was the expectation that some evidence of the postulated deep western boundary current would be found along the eastern side of New Zealand and the Tonga–Kermadec Ridge—kinematical, through advection of properties such as temperature, salinity and oxygen; and dynamical, through an intensification of the field of horizontal density gradient. No attempt was made to make direct measurements of the velocity field such as those by Swallow and Worthington[4] in a similar current in the North Atlantic

The evidence for the current on the salinity profile at 28° 15′ S consists of a salinity maximum layer with highest values (greater than 34 730‰) compressed within 70 km of the eastern slope of the Tonga–Kermadec Ridge, between the depths of 3,000 and 4,000 m A somewhat thicker (between 2,500 and 4,400 m) and much broader (extending 1,300 km to the east) tongue is delineated by the 34 720‰ contour. Further eastward the salinity at these depths falls to 34 690‰ and increases monotonically with depth The deep salinity maximum is probably the last distinct evidence of the North Atlantic component of this water's origin—the extremum being continuously traceable all the way from the Atlantic sector of the Antarctic to the Pacific sector It seems, however, that the current is not as wide as might be inferred from the 34 720‰ salinity contour, but is essentially confined to the short distance of 70 km adjacent to the Ridge, because the intense horizontal gradient of temperature (and density) is confined to this narrow region The 1·10° C isotherm drops from 4,000 m, where it intersects the eastern slope of the Ridge, to 4,600 m, 70 km to the east A similar slope—downward towards the east—occurs above these levels, but the amplitude of drop diminishes with decreasing depth, thus at 2 00° C the downward drop had diminished to a change from 2,550 m to 2,650 m At 3 00° C the slope is the other way

The current, as computed geostrophically, thus appears to be 70 km wide, to be confined between depths of 2,500 m and 4,500 m (there is always some uncertainty in assigning depths of no motion), and to transport an amount of water northward amounting to 8 to 12×10^6 m³/s, which compares with 12–15×10^6 m³/s as estimated in a steady stage budget of heat, mass, salt and radiocarbon[5]

There was no such intensification of the current observed on the 43° 15′ S section; the zone of sloping isotherms is about 500 km wide (though the vertical displacements are about the same as at 28° 15′ S), and the tongue of salinity greater than 34 730‰ extends 1,100 km east of the New Zealand slope This is presumably caused both by the fact that at this latitude the current is still in transition from the zonal current that feeds it from the south and has not travelled a sufficient distance in latitude to be influenced by the change in Coriolis parameter, and to the fact that the western boundary at this latitude has an extremely gentle and prolonged slope

Second Additional Theory of Origin of Fiamme in Ignimbrites

Gibson and Tazieff[1] have questioned a widely accepted explanation of dense black clots of glass (fiamme) in ignimbrites A new interpretation of these features is long overdue, for the conventional interpretation of fiamme as flattened and highly compressed lumps of pumice is very difficult to substantiate As they point out, in many ignimbrites there are few if any lumps of pumice in the upper, uncompacted levels that are large enough to produce the dense glassy clots by compression

Gibson and Tazieff interpret fiamme in the Fantale ignimbrite of Ethiopia as unexpanded lumps of volatile-rich "very fluid" glass carried up in the vent during the initial eruption They do not explain why the glass did not vesiculate until a very late stage even though it had a high temperature and volatile content and a low viscosity Perhaps the nucleation of bubbles was retarded in a crystal-poor fraction of the melt

Fiamme are common in certain of the ignimbrites of central Honduras and northern Nicaragua There, too, large pumice lumps are absent or very scarce in overlying levels of the same units Regardless of their pumice content, ignimbrites with prominent horizons of glassy clots seem to be restricted to areas directly underlain by coarse fluvial sediments This relation would suggest that the glass is not primary but a fortuitous secondary feature related to local influx of water

To test this possibility, I have compared two contrasting samples from a Miocene ignimbrite in north-western Nicaragua Analyses are shown in Table 1 No 258 is a black glass lens about 2 m above the chilled base of the unit where it overlies fluvial sand and gravel Under the microscope, the glass appears deep reddish-brown with many perlitic cracks The original vitroclastic texture is faintly preserved by thin streaks of fine opaque dust outlining original shards and fragments The abundance of plagioclase phenocrysts is approximately the same as in the surrounding rocks (about 5 per cent), lithic fragments of andesite, which are very abundant in the host rock, are fewer and smaller in the interior of the glass lenses In some areas, andesitic fragments are completely absent At their margins, the fiamme (as their name implies) extend tongues and feathery streaks into the surrounding material, so that the boundary is much less distinct than it appears on a mesoscopic scale

Table 1 CHEMICAL ANALYSES OF FIAMME AND HOST ROCK

	No. 258	No 260

P_2O_5	0 19	0 23
	99 79	99 77

N-258, Dense black glass clot about two metres above base of mesa-forming ignimbrite at Vuelta La Barranca, 3 5 km south of the Honduras border, north-west Nicaragua *N*-260, Dacitic ignimbrite strongly contaminated with xenoliths of andesite Host rock of *N*-258 Analyses were performed by Dr K Aoki

The second specimen, No 260, is taken from an adjacent portion of the same unit, but slightly below the fiamme horizon It is crowded with accidental fragments, chiefly of andesite The glassy portion consists of fine, strongly welded shards outlined by opaque dust Glass in the rims has a lower refractive index and paler colour than the interior of the shards and may be hydrated

It is evident that the two specimens are almost indistinguishable on the basis of their chemical analyses The fiamme has a higher water content and more reduced iron It also appears to have a slightly higher potassium-sodium ratio In view of the extreme heterogeneity of the highly contaminated ignimbrite, the resemblance of the two analyses is revealing It is apparent that the clot is not an uncontaminated glass of the same generation as the shards, but is chemically very similar to the mixture of shards and basic lithic fragments

The geological relations suggest that the glassy clots were formed after the ignimbrite came to rest over a bed of water-saturated sand and gravel Although the immediate base of the sheet was strongly chilled, the interior, which still retained a large amount of heat, absorbed water vapour streaming up through the fractured base Because the rate of inward diffusion of water exceeded the outward diffusion of heat, the water content of the rocks became high enough to depress the melting point until it intersected the steep temperature gradient There followed a brief period of refusion, first of the low-melting portion of the rock and next of the incorporated xenolithic fragments

If this interpretation is correct, it is apparent that analyses of fiamme do not necessarily represent a more uncontaminated portion of an ignimbrite magma, but may approach the composition of the total rock

Fossil Bivalve Shells indicate Longer Month and Year in Cretaceous than Present

ALTHOUGH Wells[1] and Scrutton[2] suggested methods of studying fossils to determine probable changes in day length, few studies have followed these suggestions We have examined fossil bivalve shells to try to determine whether the obvious growth lines on the shells are related to tidal or other environmental phenomena Although the study is continuing, some of the results already obtained are significant

Major growth bands, 1–2 cm wide, can be easily seen on the surfaces of bivalve shells Study of growth in some marine, temperate-water dwelling bivalve species has demonstrated that major growth bands defined by grooves on the shell surface are formed annually[3] These grooves may be distinguished from those formed erratically in response to sudden changes in environment such as temporary removal from water or sudden deep burial of the animal

The major growth bands that can be demonstrated to have formed annually can be seen, when the shells are examined in thin section, to be composed of approximately 300 or more very fine growth laminae These growth laminae are approximately 50μ thick in juvenile shells They attain a thickness of 100 to approximately 300μ in the second annual band A marked decrease in size of these fine growth laminae can be noted in growth bands successively older than the second annual The fine laminae may be as thin as 10μ in the last-formed growth band in shells of old adults

The fine growth laminae are commonly clustered The clusters form ridges and troughs that are discernible on the shell surface In shells of some species, twenty-four clusters of fifteen fine growth laminae occur within each annual band In shells of other species, the fine growth laminae occur in clusters of thirty, and there are twelve such clusters within each annual growth band These clusters of fine growth laminae are suggestive of, in the first case a fortnightly, and in the second case, a monthly, cycle of growth

Some specimens of a species of *Chione* living in Cholla Bay, Sonora, Mexico, were marked and studied closely during a period of more than a month to determine whether there was a relationship between the tidal cycles and shell growth as suggested by the studies of the fine growth laminae of their shells In one test sample, thirty specimens were marked and returned to their natural habitat The specimens were recovered 25 days later and observed to have added a ridge and trough to their shells In a second test, twenty-five specimens were collected from the same area on each of 34 successive days Study of the marginal growth increments of shells collected on successive days indicated that the addition of the ridges is related to the tidal cycle In a third test sample, a count of the number of ridges per shell in 464 specimens showed the number of ridges to be polymodal in distribution The number of modes corresponds with the apparent age of the animal in years determined by counting the number of major growth bands believed to have formed annually Also, the cut-off point for the first mode is 25 These data are interpreted as indicating a fortnightly periodicity of shell growth

The data at hand suggest a relationship between shell growth increments and tidal cycles in at least some bivalves Because this relationship seems to be relatively well founded in at least some living bivalve species, many shells of fossil bivalves have been examined It is possible to recognize the same major bands (believed, and in some cases demonstrated, to have formed annually), the very fine growth laminae and the clusters to ridges and troughs of the fine growth laminae in shells of some fossil species as were seen in shells of living species

In particular, specimens of *Idonearca vulgaris* (Morton) from Late Cretaceous age strata from several North American localities show these features most clearly There are between eight and twelve bands of the type considered to have formed annually on most of the adult shells of *I vulgaris* which were studied (It may be noted here that most bivalves living in wild conditions have a life span of 8–12 yr) The major bands, herein interpreted to have formed annually, were observed to be comprised of ridges and troughs that are clusters of fine growth laminae similar to those seen on living species On the shells studied there is an obvious grouping of twenty-four or twenty-five ridges on each major band Because drawing a precise boundary between the ridges of adjacent growth bands is relatively subjective, the ridges were counted in a continuous series across a number of major bands on each shell. The resulting number of ridges per band were weighted in relationship to the number of bands per shell involved in the count to obtain the mean number of ridges per band This value in all the shells examined is 24 98 with a standard deviation of 0 04 This figure is considered to indicate, using the implications of the studies of shells of living species, that there were 24 98 fortnightly cycles in the Late Cretaceous year If there were 24 98 such cycles in the Late Cretaceous, then there were 12 49 lunar months in the Late Cretaceous year

Many unbroken successions of the fine growth laminae were studied in shells of *Crassatella vadosus*, a species found in association with *I vulgaris* in many deposits The major growth bands in the shells of *C vadosus* are delimited by sharply incised grooves related to abrupt changes in shell curvature Ridges and troughs similar to those observed in *I vulgaris* and in many living species were also seen on shells of *C vadosus* The ridges are composed of fine growth laminae A count of 1,095 fine laminae across thirty-seven ridges in eight different shells of *C vadosus* yielded a weighted average of 29 65 fine laminae per ridge with a standard deviation of 0 18 This average is interpreted to indicate that there were 29 65 days in the month in the Late Cretaceous (compared with 29 53 at present)

Combining the data from this study of Late Cretaceous bivalve shells suggests that there were $29\ 65\times12\ 49=370\ 3$ days in the Late Cretaceous year This figure can be compared with astronomical estimates of the number of days in the year in the past As Wells[1] noted, astronomical data indicate that the Earth's rotation has been slowing down at about 2 s/100,000 yr At the beginning of the Cambrian, day length was about 21 h if the present rate of deceleration has been maintained from the beginning of the Cambrian, about 6×10^8 yr ago[4] Length of day has thus apparently been increasing throughout time and the number of days in the year decreasing Wells[1] indicated, in a plot of the number of days in a year against time in millions of years, that astronomical data lead to an estimated 371 days in the year near the end of the Cretaceous The number of days in the year in the Late Cretaceous obtained from the study of shells of Late Cretaceous bivalves is thus quite close to that derived from astronomical data.

Wells[1] suggested that there were approximately 400 days in the year in about Mid Devonian time, based on his studies of growth increments in tetracorals The number of days in the year in the Middle Devonian derived from astronomical data, assuming the present rate of deceleration in the Earth's rotation has been maintained since the Cambrian, is consistent with the number of days obtained from the study of fossil material The data from both Devonian tetracorals and Late Cretaceous bivalves thus appear to be consistent with those from astronomical evidence The results of this study support Wells's[1] suggestion that the study of fossils may provide a third line of evidence to geophysical and astronomical estimates of the age and history of the Earth

Calcium Carbonate Content of Karst Water in relation to Flow-through Time

MEASUREMENT of the primary porosity of massive limestone gives little indication of the rate of underground movement, which takes place largely along joints and bedding planes There is also the possibility that these zones of water movement can exist as discrete systems and not in a uniformly permeable interconnected lattice[1] Consequently, the permeability of a stratum of any fractured rock is difficult to estimate The purpose of this communication is to report a finding which reinforces the hypothesis that the flow-through time of water in massive limestones might be inferred from seasonal changes in the solute concentration of the water[2]

It has been observed that "karst spring water", supplied from precipitation which has fallen only on limestone and which remains unaffected by dilution by run-off from non-calcareous outcrops, may show a clearly marked correlation between seasonal variations in the amounts of calcium carbonate in solution and antecedent air temperatures The relationship seems to reflect the increased carbon dioxide output in the plant root zone of the soil at higher temperatures[1] The lag between the air temperature midsummer peak and the subsequent peak in the chemically altered water should therefore indicate the flow-through time of the water The approximate length of the lag can be identified by calculating correlation coefficients between the measurements of calcium carbonate content of the karst water, and air temperatures averaged for periods at progressively greater time intervals before each of the sampling days Using a preset interval spanning 3 weeks, the calcium carbonate observations are correlated first with air temperatures for the 0–20 day period before sampling, then with those for 21–41 day period before each sampling day, followed by those for the 42–62, 63–83, 84–104 day and progressively earlier intervals

Between February 1962 and June 1965 karst water samples were collected monthly for a 1 or 2 year period from nearly 100 sampling points in the southern and central Pennines Eighteen of these points, mostly underground, show a very close correlation between antecedent air temperature and the calcium carbonate content of the drainage or cave-seepage water These include all the stations of those analysed so far where the antecedent temperature factor extracts more than 50 per cent of the variance in 12 monthly samples In eight cases this factor accounts for more than 80 per cent of the variance (Table 1).

In the case of the *S*1 seepage in Ingleborough Cave, near Clapham, the correlation coefficients are $r=0{\cdot}76$ for the 21–41 day period, $r=0{\cdot}94$ for the 42–62 day period and $r=0{\cdot}91$ for the 63–83 day period In this case, it seems that the correlation is closest for a longer time lag than indicated by the mid-point for the 42–62 day period In Table 1, therefore, column 5, the time at which the correlation might be closest has been estimated by interpolation based on the degree of correlation shown by the 3 week preset intervals on each side of the interval showing the highest correlation

As Fig 1 shows, the estimated flow-through time seems to determine the mean calcium carbonate content rather closely, regardless of the locality in the Pennines, or whether the water sampled is an underground or surface stream, cave seepage or stagnant pool The demonstration of this relationship is not only of geochemical significance but also supports the argument that the lag between antecedent air temperature and the subsequent correlated changes in calcium carbonate concentration is a reliable measure of the flow-through time in massive limestones

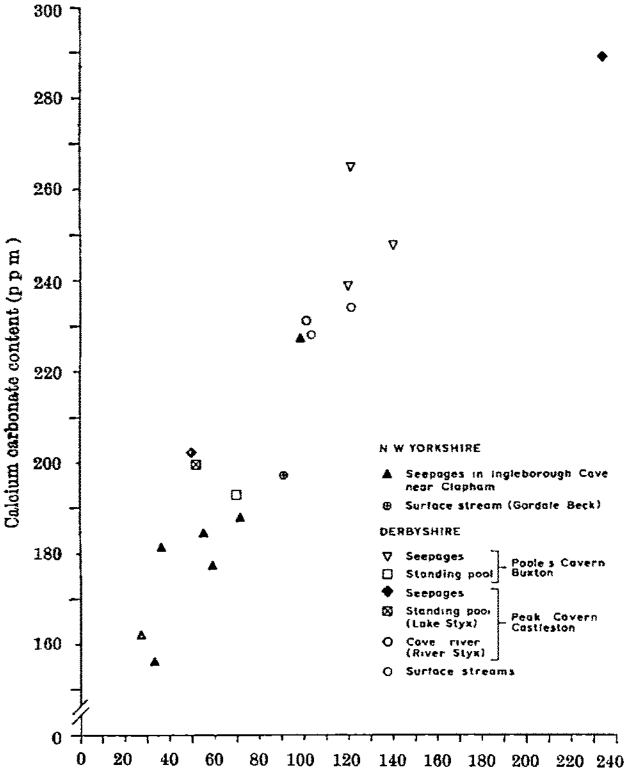

Fig 1 The relationship between estimated flow-through time and mean calcium carbonate content of karst waters from the southern and central Pennines The equation of a straight-line relationship, fitted by the method of least squares, is $y=0{\cdot}667x+152{\cdot}56$ There is, however, no reason to assume either that this is an adequate representation or that a curvilinear relationship would be more accurate

PHYSICS

Drag Reduction by Bacterial Metabolites

In conditions of turbulent flow, relatively low concentrations of linear, high-molecular weight polymers can greatly reduce the frictional drag of a liquid[1–4] By measuring the pressure drop along a finebore tube in these conditions, the drag-reducing potential of such a polymer solution can be estimated by comparing with the pressure drop for the pure solvent. This is the principle on which the turbulent flow rheometer[5] is based

Only recently have living organisms been shown to produce drag-reducing materials The marine dinoflagellate, *Prorocentrum micans*, and the marine diatom, *Chaetoceros didymus*, have been found to be good friction reducers when they are grown in synthetic media[6–8] When their menstrua were tested for drag-reduction effectiveness, values greater than 25 per cent were obtained Similarly, reductions were achieved by the freshwater algae, *Anabaena floss-aquae*, *Chlamydomonas peterfii* and *Porphyridium aerugineum*, and by extracts of many seaweeds, including *Chondrus crispus*, *Ulva rigida* and *Fucus furcatus*

Little work has been done on bacteria as a source of drag-reducing materials 'Kelzan' (Kelco Company, San Diego, California), a bacterial polysaccharide produced by *Xanthomonas campestris*, is effective a 50 p p m solution reduced friction 36 per cent, a 100 p p m solution, 50 per cent, and a 200 p p m solution, 62 per cent Greater concentrations did not enhance reduction

Because bacteria are ubiquitous and produce diverse metabolites, the purpose of the investigation described here was to study the potential of bacteria as drag reducers

Bacteria were cultivated on a medium (TYGS) composed of the following 5 g of tryptone (Difco), 5 g of yeast extract (Difco), 5 ml of glycerol, 5 g of sucrose,

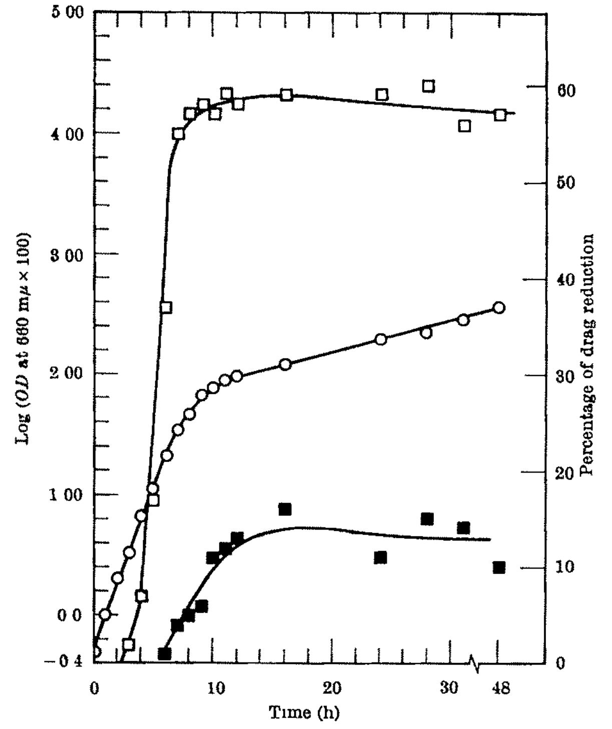

Fig 1 Drag reduction by *Pseudomonas* species in relation to the growth curve (○) A TYGS broth culture was tested for drag reduction full-strength (□) and after a 1 10 dilution (■)

5 g of glucose, 1 g of K_2HPO_4 $3H_2O$, and 1 l of de-ionized water For the cultivation of marine bacteria, K_2HPO_4 $3H_2O$ was replaced by NaCl (20 g) and 'Rila' (Rila Products, Teaneck, N J) marine salts (5 g) Solid media were prepared by the addition of 2 per cent agar (Difco) to the liquid medium The *p*H was adjusted to 7 6 with NaOH and sterilized by autoclaving

Initial studies to demonstrate drag reduction by bacterial metabolites involved agar-grown cultures Each organism tested was inoculated on to a TYGS-agar Petri dish and incubated at room temperature, approximately 25° C Four inoculating loops of each culture were collected for periods up to 7 days, suspended in 10 ml of de-ionized water, and tested immediately for drag reduction effectiveness in a turbulent-flow rheometer Synthetic sea water (35 g of 'Rila' marine salts/l) was used to suspend marine bacteria

Some bacteria that exhibited significant drag reduction capabilities (greater than 5 per cent) are described in Table 1 Bacteria found to be positive friction reducers were observed for the presence of capsules, for moistness, for butter-like consistency and for a pituitous quality (manifested by a colony sticking to the inoculating loop and producing an elastic, string-like extension), because these characteristics indicate the production of extracellular metabolites Capsule formation was discerned by means of indirect staining with india ink

Table 1 DRAG-REDUCING BACTERIA

Organism	Source	Capsule	Colony description
Pseudomonas sp	California State College, Los Angeles	−	Pituitous
Bacillus sp	California State Polytechnic College, Pomona	+	Pituitous, moist

Figs 1, 2 and 3 illustrate the kinetics of friction-reducing metabolite production in relation to the growth curves of species of *Pseudomonas*, *Bacillus* and *Neisseria*,

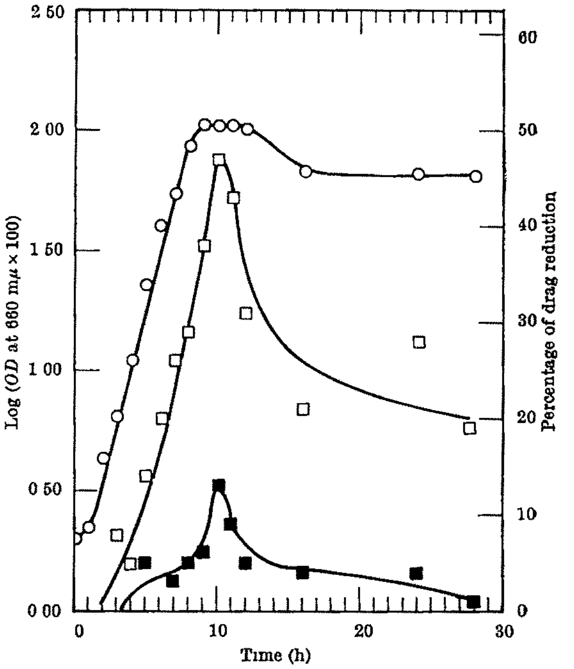

Fig 2 Drag reduction by *Bacillus* species in relation to the growth curve (○) A TYGS broth culture was tested for drag reduction full-strength (□) and after a 1 10 dilution (■)

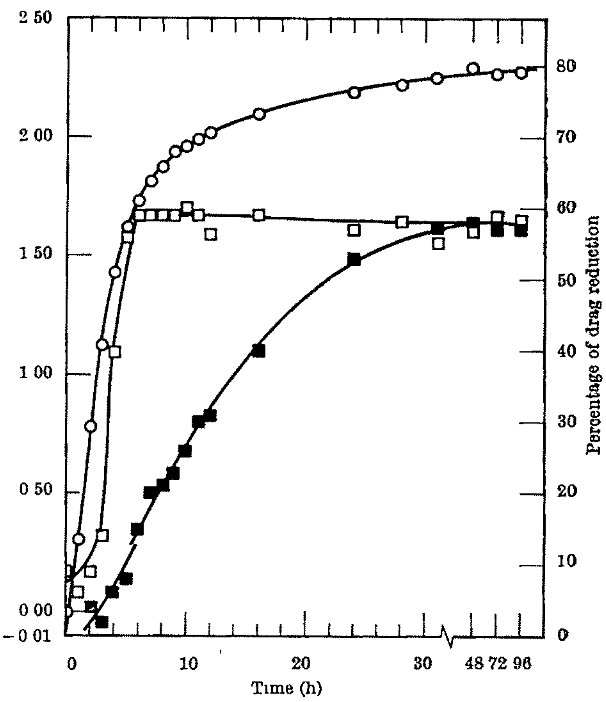

Fig 3 Drag reduction by *Neisseria* species in relation to the growth curve (○) A TYGS broth culture was tested for drag reduction full-strength (□) and after a 1 10 dilution (■)

respectively A sample (20 ml) of broth culture was inoculated into 300 ml of TYGS broth in a 1,000 ml Erlenmeyer flask, which was shaken at room temperature Portions of 5 ml were withdrawn once every hour for 12 h, and then after varying periods Turbidity was estimated at 660 mμ by means of a Bausch and Lomb Spectronic 20' colorimeter equipped with an infrared-sensitive phototube and red filter A 1 10 dilution of each sample was also made and the drag-reduction capabilities of both were estimated in a turbulent flow rheometer Preliminary studies indicated that the presence of bacterial cells had no significant effect on drag reduction

The production of friction-reducing metabolites increased rapidly and concomitantly with logarithmic culture growth (Figs 1, 2 and 3) Following logarithmic growth, however, different trends were noted for each culture At the end of exponential growth, the friction reduction by the *Pseudomonas* culture remained at approximately 58 per cent *Bacillus* species showed a decrease in friction reduction from about 47–20 per cent following exponential growth The 1 10 dilution of the culture showed a similar trend This indicated the degradation or utilization of the drag-reducing substances following logarithmic growth Friction reduction by the *Neisseria* culture remained constant at about 59 per cent after exponential growth Drag reductions from the 1 10 dilutions, however, continued to increase to the 59 per cent level, which indicated the continued production of drag-reducing materials after the logarithmic phase This merely means that the concentration of metabolite in the culture was in excess of that required to give maximum drag reduction

Fig 4 illustrates the effect of shear on drag-reducing materials derived from *Achromobacter fisheri* and *Pseudomonas* species cultures The friction of a 1 10 dilution of the culture after the first and third pass through the rheometer is plotted as a function of the age of the culture Each pass through the instrument subjects the dissolved polymers to shear The metabolites from both bacteria were subject to shear, as indicated by the difference between the curves Earlier research had shown that shear increases drag by decreasing molecular length[5]

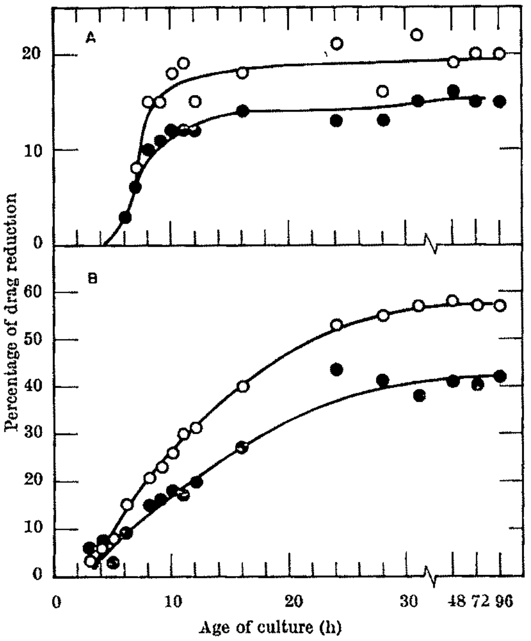

Fig 4 Shear effects on *Achromobacter fisheri* (*A*) and *Neisseria* species (*B*) drag-reducing metabolites in relation to culture age A 1 10 dilution of the culture was tested for drag reduction after the first pass through the rheometer (○) and after the third pass (●) The difference between the curves indicates the effect of shear

The results of this investigation clearly demonstrate that some bacteria can enhance the drag-reducing properties of their culture medium As Table 1 shows, bacteria isolated from many habitats were effective While many bacteria were found to be effective drag-reducers, however, many were not *Aerobacter aerogenes*, *Bacillus cereus*, *Serratia marinorubra*, *Staphylococcus aureus*, *Leuconostoc mesenteroides*, *Escherichia coli* and others were found to be ineffective

No attempt was made to isolate or purify the friction-reducing components of the bacterial cultures in this study High molecular weight extracellular polysaccharides or polysaccharide–protein conjugates, however, are likely causative agents High molecular weight, soluble, linear macromolecules are known to produce friction-reducing effects in turbulent-flow conditions 'Kelzan', a commercially produced bacterial polysaccharide with little branching and an estimated molecular weight of 6×10^6, was very effective Hyaluronic acid, a polymer that consists of repeating units of glucuronic acid-1-β-3-*N*-acetylglucosamine, is a component of some extracellular bacterial polysaccharides[9,10] Purified hyaluronic acid from a mammalian source was shown to reduce drag by more than 30 per cent in a concentration of 200 p p m (ref 5)

Bacteria affixed to phytoplankton, decomposing organic matter or other inanimate or animate objects, or even non-attached bacteria, may have sufficient nutrients available to promote the synthesis of extracellular drag-reducing metabolites These metabolites may have a pronounced effect on hydrodynamic test results, and so the marine designer should take their potential into consideration, as well as the marine diatoms, dinoflagellates, seaweeds and freshwater algae which have also been shown to be important in this respect

The drag-reducing properties of some bacterial macromolecules may make them suitable for quantitative measurements based on drag-reduction estimates This may be a useful procedure in studying extracellular polysaccharides, natural and induced leakage and lysis products, and rates of polymerization and depolymerization Further investigations are needed to explore these possibilities, as well as to examine the effects of other factors on the production of bacterial drag-reducing metabolites *in situ*

These studies were aided by support from the Microbiology and Fluid Dynamics Branches of the Office of Naval Research I thank all those whose gifts of bacterial samples made this work possible

Observation of Surface Vibration Modes by Stroboscopic Hologram Interferometry

Powell and Stetson[1] have shown that holography can be used to study the vibration modes of a surface The technique they employed was to record a hologram while

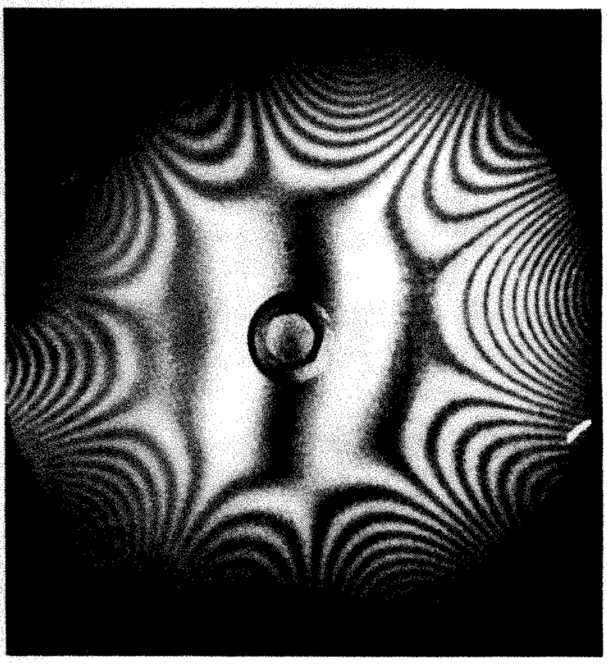

Fig. 1. Interference fringes on a white-painted aluminium disk vibrating at a resonant frequency of 3.074 Hz. Fringe motion is arrested by stroboscopic illumination.

the surface was actually vibrating. The reconstructed image from such a hologram varies in brightness with the total excursion of the surface movement, and gives a kind of "time-averaged" contour map of the vibration amplitude. We wish to report a method of real-time analysis of the surface shape and to demonstrate its advantages.

Interference effects can be obtained between an object and its holographically recorded image if the two are superimposed[2-4], by replacing the processed hologram plate in exactly the same position in which it was recorded, and viewing the object through the hologram plate using the same illuminating conditions. A slight displacement of the surface of the object will then give rise to a pattern of interference fringes, from which can be calculated the degree of displacement of the surface in a direction bisecting the illuminating and viewing directions. The appearance of the fringe pattern is independent of the roughness or otherwise of the surface. For a surface vibrating normal to its plane, the interference fringes will sweep across it in synchronism with the frequency of vibration, so that by pulsing the illumination at this frequency, their motion can be arrested and the distortion of the surface, measured relatively to its rest position, can be deduced.

In experiments on an aluminium disk 180 mm in diameter, bolted centrally to a piezo-electric transducer, a hologram of the stationary disk was first recorded. The laser beam, before being diverged to illuminate the disk, was first focused through a 0·375 mm hole drilled diametrically across a steel spindle 4·5 mm in diameter. In the image reconstruction stage this spindle could be rotated by means of an air-driven turbine to speeds in excess of 100,000 r.p.m. so that the illumination was pulsed at double this frequency (0–3·5 KHz). The transmitted pulse duration was approximately one-twentieth of the time interval between pulses. To achieve synchronization of the vibrating disk with the pulsed illumination, a small fraction of the light from the laser was split off and directed onto the end of the rotating spindle, on which was mounted a small circular front-surfaced mirror faced with a piece of polaroid. Because the laser beam is polarized, the light reflected from this combination of mirror and polaroid will vary periodically in intensity at the same frequency as the pulsing beam (2 cycles per revolution). This reflected light was then focused onto a photodetector, the output of which was amplified and used to drive the transducer. By altering the angle of the plane of polarization of the original synchronizing beam, it was possible to vary the phase of the drive signal relative to the illumination pulses. A photograph of the interference fringe pattern obtained at a resonant frequency of 3,074 Hz is shown.

Vibration analysis by interferometry is in general performed at normal incidence, in which case it has a high intrinsic sensitivity, because successive interference fringes are effectively contour lines spaced at intervals of one-half wavelength amplitude. This is especially advantageous at higher frequencies, where the amplitude of motion may be small. The fringe patterns viewed stroboscopically enable the vibration modes to be examined over the full frequency range and ciné records can be made. In this way sharp resonance conditions can be detected. For example, the resonance of which the interference pattern is shown in Fig. 1 had a very narrow bandwidth, such that the frequency had to be held within 0·5 Hz for it to remain stable. A resonance of this kind would almost certainly be missed if the "time-averaged" hologram method were used. In addition, provided that the pulse duration is a sufficiently small fraction of the periodic time, a greater number of fringes can be viewed stroboscopically. This follows from the intensity distribution of the two types of fringe pattern. For real-time fringes, for an infinitely short pulse duration, the intensity is proportional to $\sin^2(2\pi a/\ )$, while for the "time-averaged" fringes it is proportional to $J_0^2\,(4\pi a/\lambda)$ (where a is the amplitude and λ is the wavelength). The peaks of the latter distribution become progressively smaller with increase of a, but not so the former. By watching the development of the fringe pattern stroboscopically, as either the frequency or amplitude is changed, it is possible to determine the order number of any fringe and so to know the displacement of the surface at that point, whether or not there exists a node.

To follow the waveform of an oscillating surface, one merely has to change the relative phase of the drive signal and pulsing beam. By this means the presence of harmonics can be detected. It is also possible to determine whether different parts of the surface are oscillating in phase or in anti-phase, by giving the surface a slight displacement in the normal direction and noticing the direction in which the fringes move. The stroboscopic method will, of course, also show the presence of a progressive wave motion.

Possible Explanation of Anomalies in Neutral *K* Phenomena

The experimental results usually interpreted as evidence for CP violation in neutral K decay have been found[1] to be inconsistent with the values of all the relevant observables obtained from other measurements. In particular, either the K_L–K_S mass difference or the difference $(\delta_2-\delta_0)$ between two pion–pion scattering phases, as determined from a phenomenological analysis[1] of the former data, has an opposite sign from that obtained by independent measurements of these two quantities. (The measurements of the sign of the mass difference have been summarized in ref. 2, and the independent determination of the sign of $(\delta_2-\delta_0)$ is backed by a considerable body of evidence; see ref. 3.)

This result, taken at face value, cannot be accounted for by any existing CPT-conserving theory of CP violation. Such a possibility can, however, be accommodated within, and in fact was predicted[4] by, the theory in which the effects in question are due not to CP violation but to the interaction of neutral K mesons with external electromagnetic fields. A possible change in sign of the effective K_L–K_S mass difference Δ in the presence of external fields was expressly considered by Spitzer[4] in connexion with equation (9) of his paper. (This equation was derived under the working hypothesis that the proposed interaction contributes primarily to the real mass matrix M, but not to the decay matrix Γ. The result that Δ can change sign is more general than equation (9) and holds even if the above assumption does not, but the form of this equation as well as the stated conditions[4] in which the sign change can occur have to be modified if both M and Γ depend appreciably on the external field.)

The coupling between neutral K and electromagnetic fields leading to such an effect was originally proposed[5] in connexion with other considerations, based on the more general phenomenon of associated production and the observed equality of the domains of validity of this phenomenon and of parity conservation. According to these considerations the two domains are equal because they are physically identical[5,6]. The proposed interaction is invariant under P and C (separately) and is non-minimal. It leads to K^0–$\bar{K}^0$ interconversion in the presence of suitable external fields[4,6] and accordingly modifies the propagation and decay characteristics of the neutral K. For example, the states K_L and K_S that exhibit simple exponential time dependence in such fields, for example, a longitudinal magnetic field, will in general be linear combinations[3] of the states K_1 and K_2 that exhibit such time dependence in the absence of matter and of external fields. Also, the effective mass difference and lifetimes of K_L and K_S will be field dependent[4,6].

The interaction leads to K_1 regeneration from K_2 by external fields[4], which entails reappearance at large distances from the target (even in the absence of matter) of 2π decay modes[4] and, through interference between K_L and K_S, of a charge asymmetry in leptonic decay. Such an asymmetry has recently been observed[7,8]. An additional possible cause of charge asymmetry, if the assumed interaction is present, is that the field-independent and field-dependent parts of the amplitudes for leptonic decay of K^0 transform under CP with a relative minus sign (for a fixed external field). This source of charge asymmetry is almost completely independent of the composition of the neutral K in terms of K^0 and $\bar{K}^0$ and therefore contributes even after the interference term has died out. As will be elaborated later, the field-dependent part of the decay amplitude is linear in the external field, so that it may be possible to vary the degree of asymmetry by changing either the magnitude or the direction of the external field.

The theory predicts that the regeneration rate may saturate in its field dependence, depending on the values of the unknown field-independent parameters. Without detailed knowledge of the field strengths and configurations in the relevant experiments it is not possible to determine these parameters on the basis of existing data. Because of the possibility of saturation, the regeneration effect may not be the most suitable one for a quantitative study of the interaction. Any dependence of, for example, the anomalous 2π decay rate on the longitudinal magnetic field[4] would, however, establish its presence qualitatively. A more promising approach to a quantitative study is likely to be provided by measuring the field dependence of Δ, but it is premature to consider this aspect of the problem until further qualitative information becomes available.

Although the proposed interaction[5,6] depends on the electromagnetic field bilinearly through the pseudoscalar $\mathbf{E}\cdot\mathbf{H}$, it seems unlikely that any of the experiments in question involved external field configuration with a finite value of $\mathbf{E}\cdot\mathbf{H}$. If the effects that have been attributed to CP violation are in fact due to the interaction of the neutral K with external fields, the relevant amplitude for field-induced K^0–$\bar{K}^0$ interconversion or K decay is, to lowest order, almost certainly linear in the external field[4,6]. The origin of such an amplitude is considered here.

The effects resulting from an amplitude for K^0–$\bar{K}^0$ interconversion or K decay which is linear (bilinear) in the external electromagnetic field will be referred to as the linear (bilinear) effects, but it must be kept in mind that the actual dependence of the various observables on external fields is in general considerably more complicated[4,6] than this terminology might suggest.

The linear effects can occur because a virtual photon can couple singly to a neutral K or to some of its decay products through known interactions. One of the photons from the vertex where the electromagnetic field acts bilinearly to interconvert K^0 and $\bar{K}^0$ can thus couple internally while the other is exchanged with the external field.

It should also be mentioned, in connexion with the linear effects, that because a π^0 cannot couple to a single photon, even to a virtual one, the lowest-order field-dependent part of the amplitude for $\pi^+\pi^-$ decay has no counterpart for $2\pi^0$ decay. The field dependence of the latter thus provides a measure of the external-field contribution to the complex mass matrix $(\Gamma+iM)$. (This remains true even in the presence of the bilinear effects, for the matrix elements proportional to $\mathbf{E}\cdot\mathbf{H}$ contribute only to M, not to Γ or to any of the decay amplitudes.) On the other hand, the field dependence of $\pi^+\pi^-$ decay has its origin in both the complex mass matrix and the decay amplitude. Hence the ratio of the partial decay rates of the neutral K into the charged and neutral 2π modes may be field dependent. A study of 2π decay can therefore provide important information on the extent to which the proposed interaction contributes to the decay amplitudes and on its relative contributions to M and Γ.

Finally, there is an aspect of the linear effect that bears on the question of the relative magnitude of the two kinds of amplitudes for leptonic decay. Denote by f and g the field-independent amplitudes

$$K^0\rightarrow\pi^-l^+\nu : f$$
$$\bar{K}^0\rightarrow\pi^-l^+\nu : g$$

and by A and B the field-dependent amplitudes

$$\bar{K}^0\rightarrow\pi^-l^+\nu : A$$
$$K^0\rightarrow\pi^-l^+\nu : B$$

Existing experiments (summarized, for example, in ref. 9) place an upper limit of $\sim 0{\cdot}2$ on the parameter $|g/f|$. Of interest here is the fact that even if g is zero, the proposed interaction can lead to phenomena generally believed to require the presence of both f and g. The point is that the non-minimal coupling interconverts K^0 and $\bar{K}^0$ and therefore, when acting together with the decay characterized by f, it leads to the field-dependent process characterized by A, not to the one characterized by B. Thus the amplitude f and the non-minimal interaction can combine to simulate the presence of the amplitude g. If the field dependence of neutral K phenomena is confirmed experimentally, it becomes imperative that in testing for the possible presence of the amplitude g both the electric and magnetic fields be minimized in the region of interest.

More generally, if the interaction with electromagnetic fields is responsible for the anomalous effects, such as 2π decay and charge asymmetry at large distances from the target, then these can all be completely eliminated by properly shielding the external fields. It is emphasized that such null experiments can serve not only to establish the presence of the proposed interaction, but in addition would dispel a related conceptual question. Specifically, the total absence of evidence for *CP* or *T* violation in any phenomena not involving neutral *K* mesons is very puzzling if the anomalous effects are interpreted as evidence for *CP* violation in neutral *K* decay. If, however, these effects can be accounted for within the framework of *CP* invariance, as discussed here and earlier[4,5], there is then no longer any reason to expect such violation elsewhere.

I thank S. Schneider for helpful suggestions. This work was performed under the auspices of the US Atomic Energy Commission.

Characteristic Energy Loss of Electrons transmitted through Argon

Interpretation of kinetic-to-internal energy transfers in many-electron heavy particle ionizing collisions[1,2] has demonstrated the importance of looking for possible large characteristic energy losses in electron scattering. Previous workers[3-5] have studied levels < 100 eV. Most X-ray absorption studies[6] do not use continuum sources but characteristic line sources. Heavy particle collision energy losses might arise not from diabatic curve crossing[7] but from collective oscillation of electrons[8].

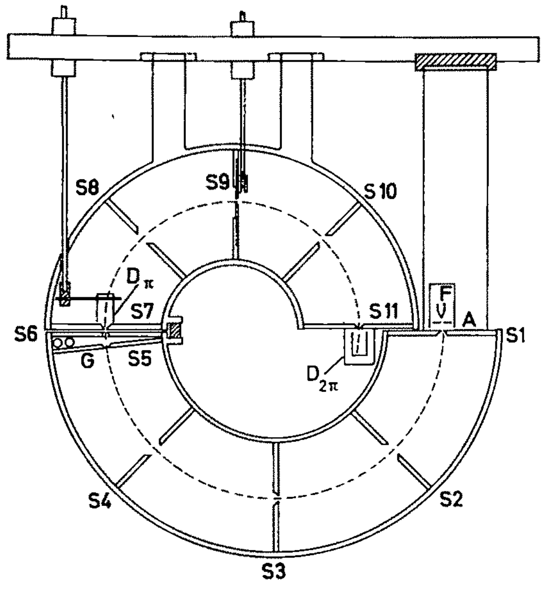

Fig. 1. Schematic diagram of apparatus.

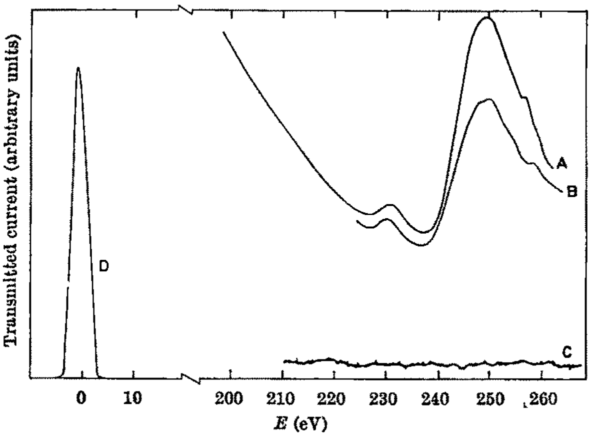

Fig. 2. Part of energy loss (E) spectrum for argon, for forward scattered 1,100 eV electrons. A, B, Typical runs; C, background spectrum in absence of gas; D, elastically scattered beam.

We have conducted a Born–Bethe approximation[9,10] zero angle electron scattering energy loss search for unidentified levels in argon, using a double 180° magnetic electron spectrometer. Because[11] the cross-section $\sigma \propto E^{-3}$, then, for a level $E \sim 200$ eV, σ will be so small that any electron spectrometer must possess high efficiency, at the expense of resolution.

The spectrometer (Fig. 1) is in a uniform magnetic field. Electrons from tungsten filament F are accelerated through anode A up to their full primary energy 1,100 eV at S_1. The 180° magnetic monochromator slits S_2–S_5 are equipotential. Gas at pressure ~0.1 torr is passed into the collision chamber G. After collisions, the electrons passing through S_6 are retarded to an energy appropriate to the 180° magnetic analyser composed of slits S_7–S_{11}, all equipotential. The monochromator and analyser slits are, respectively, on circles of radii 3 in., 2.25 ± 0.0005 in. Widths are as follows: $S_{1,5,6,7,11}$, 0.010 in.; S_3, 0.020 in.; S_9, 0.033 in.; $S_{2,4}$, 0.100 in.; $S_{8,10}$, 0.200 in.

Slit S_9, adjustable radially, was tuned for maximum electron current at zero scattering angle, within resolution 1.5°. There is high order focusing at S_{11}. The Faraday cup D_{π} could be moved into the beam path for tuning the monochromator by magnetic field variation. At constant magnetic field, the analyser was tuned to transmit the unscattered beam to the Faraday cup $D_{2\pi}$, by adjustment of the analyser potential, the scanning of which allows collection of electrons scattered with energy loss.

Fig. 2 shows typical Ar energy loss spectra, around the $L_{2,3}$ edge, for electrons of 1,100 eV initial energy. The measured overall spectrometer resolution ≃3 V. Those of the analyser and monochromator calculated from orbit theory are, respectively, 2.5 and 3.5 V. The spectrum shows excitation and ionization of M shell electrons, $L_{2,3}$ inner shell ionization edges[12] at 247 and 245 eV, and structure at 258 eV resulting from simultaneous ionization of L ($2p$) and M ($3p$) electrons. Auger transitions from this level have been reported[13]. The most interesting feature is the unidentified peak at ~230 eV, for which an oscillator strength ~0.01 is found, normalizing against X-ray data[6]. Excitation of an $n=2$ electron into $n=3$ ($1s^2\,2s^2\,2p^5\,3s^2\,3p^6\,nl$) might account for such an energy. Slater's rules[14] show that all such levels lie within 3 eV of the $L_{2,3}$ edges, and some have been identified in Auger transitions[15] and in X-ray absorption[16]. This identification of the 230 eV level is not possible. Slater's rules also show that for a 230 eV level to be produced by excitation of $n=3$ electrons, all eight must be involved. Reports of this and a similar experiment, using a different type of spectrometer, were given recently[17,18]. Structure around 230 eV showed up clearly in both spectra In scattering through non-zero angles (> 30′) the feature disappeared The measurement of single electron energies in heavy particle ionizing collisions[13] shows no peak arising from this level The inference is that the level, in decaying, distributes its energy among several electrons

We submit that this 230 eV energy loss peak could be caused by the collective excitation of a number of electrons

CHEMISTRY

Mass Spectrometric Analysis of Oxygen

We have recently analysed a sample of medical oxygen by mass spectrometry, and found that the level of carbon monoxide, approximately 1 per cent, far exceeded the toxic level for humans Subsequent investigation of the literature disclosed that this phenomenon is to be expected because of the interaction of oxygen with carbon impurities in the hot tungsten filament of the mass spectrometer electron gun[1-3] In a mass spectrometer, used for general analysis of organic compounds, there is the additional possibility that carbide is formed on the tungsten surface which may then react with oxygen in the system Carbides of rhenium have the advantage of being less stable than those of tungsten and this has led to the widespread use of rhenium filaments Even with a rhenium filament, however, significant quantities of carbon monoxide are produced in oxygen analysis

The construction and use of a windowless photoionization source suitable for the *M S* 9 have been described[4-6] The occurrence of reactions on the filament and the hot ion chamber in the electron bombardment source of the *M S* 9 has been shown and it has also been shown that these effects can be minimized using photoionization[7] Using a newly designed ion source (to be published) permitting simultaneous use of electron and photon beams, the analysis of oxygen has been re-examined

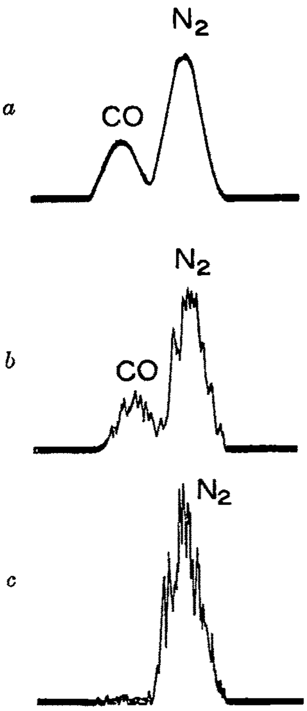

Fig 1 Doublet at m/e = 28 *a*, Electron source 200° C, *b*, photoionization source 200° C, electron energy (E < I P) *c*, photoionization source 20° C

Fig 1*a* shows the mass 28 multiplet observed when oxygen is introduced at 10^{-6} torr into an AEI *M S* 9 mass spectrometer using electron bombardment from a rhenium filament with an ion source temperature of 200° C The nitrogen peak originates from a small impurity in the ordinary tank oxygen used for this experiment The significant carbon monoxide peak largely disappeared when the oxygen flow was stopped and is thus caused by the reaction with the filament and hot ion source Fig 1*b* shows the appearance of the multiplet using photoionization by the helium 584 Å resonance line with the filament also switched on and the ion source ambient temperature at 200° C The electron energy was set at 5 V so that no ionization could occur by electron impact (Switching off the photon beam in these conditions gave zero ion current, thus confirming the absence of stray high energy electrons) Fig 1*b* shows the presence of carbon monoxide as in *a* Fig 1*c* shows the observed ion current at m/e = 28 when photoionization alone is used at a source temperature of 20° C The carbon monoxide has virtually disappeared

The use of photoionization is obviously of advantage where the mass spectrometric analysis of reactive gases is to be undertaken

Detection of Oxygen Atoms during Gamma Radiolysis of Carbon Monoxide Gas

IT has been suggested[1] that the yield of carbon dioxide, formed during radiolysis of carbon monoxide gas at atmospheric pressure and ambient temperature, results from the reaction of oxygen atoms with carbon monoxide The principal evidence in support of this is the observation that during proton irradiation G (CO_2) is decreased from 2 to 0 5 (molecules/100 eV) as the dose rate is increased from 5×10^{15} to 10×10^{18} eV ml $^{-1}$ s^{-1} The effect was interpreted in terms of the reaction sequence

$$\begin{aligned} CO &\rightsquigarrow C + O \\ C + CO &\rightarrow C_2O \rightarrow \text{polymer} \\ O + CO &\rightarrow CO_2 \\ O + C_2O &\rightarrow 2CO \end{aligned}$$

This communication describes chemical evidence for the formation of oxygen atoms and an estimate of the yield of these intermediates in irradiated carbon monoxide

Propene was used as an oxygen atom scavenger Cvetanović has shown[2] that $O(^3P)$ atoms generated during the 2537 Å mercury sensitized photolysis of nitrous oxide

$$Hg^* + N_2O \rightarrow N_2 + O(^3P) + Hg$$

react with propene to form chiefly propene oxide and propanal with similar yields, small quantities of acetaldehyde and acetone are also formed Hughes *et al* [3] confirmed this result in a study of the reaction between $O(^3P)$ and solid propene at 77° K

The experimental arrangements were conventional A 17,000 Ci source of cobalt-60 was used and dose rates were determined by ferrous sulphate dosimetry After irradiation, both the scavenger and the reaction products were separated from the unreacted carbon monoxide by slowly pumping the contents of the vessel through a spiral trap half immersed in liquid nitrogen The trap was designed to be fitted to a gas chromatography unit by means of a switch-over valve The reaction products were identified and quantitatively estimated using a Perkin-Elmer model 452 gas chromatograph with a flame ionization detector A 2 m column of polyethylene glycol on 'Chromosorb *P*' and a 2 m pre-column of tetra ethylene glycol dimethylether on 'Chromosorb *P*' were used The pre-column ensured a good separation between the olefine scavenger and the reaction products Quantities of the order of 10^{-8} moles of product could easily be detected The experiments were performed at a dose rate of about 3×10^{13} eV ml $^{-1}$ s^{-1} in vessels of 145 ml capacity at 22° C

Irradiation of carbon monoxide containing propene was found to result in the formation of products characteristic of the reaction of $O(^3P)$ atoms with propene The G values of these products are shown in Table 1

Table 1 γ-RADIOLYSIS OF CARBON MONOXIDE AND PROPENE (0 03–0 185 PER CENT) MIXTURES AT 22° C IN THE PRESSURE RANGE 1–3 3 ATM *G* VALUES OF PRODUCTS

Product	G (molecule 100 eV^{-1})
Propene oxide	0 58 ± 0 09
Propanal	0 61 ± 0 07
Acetaldehyde	0 14 ± 0 04
Acetone	0 08 ± 0 02
Total	1 41 ± 0 22

The G values of the products were found to be independent of pressure in the range studied (1–3 3 atm) and of propene content in the range 0 03–0 185 per cent Yield-dose plots were linear to a total dose of 2×10^{19} eV With the exception of acetone, the same G values were obtained with 2 5 per cent propene mixtures At this mixing ratio G (acetone) was found to be 0 4 ± 0 04 molecules/100 eV

Cvetanović[2] reported difficulty in establishing quantitatively the extent of fragmentation of the primary association complex and suggested that addition products perhaps only account for between 70 and 80 per cent of oxygen atoms consumed One possible source of experimental error cited was the uncertainty of the quantitative recovery of the addition products from the photolysed mixture

The following experiment was designed to determine the relationship between the nitrogen and addition-product yields during the 2537 Å mercury-sensitized photolysis of nitrous oxide–propene mixtures

The experimental arrangements were similar to those described by Cvetanović[2] To avoid possible experimental error caused by preliminary fractionation of the reacted mixture by low temperature distillation, using a Le Roy still the aldehyde formed was directly extracted with water and estimated by its reaction with 2,4-dinitrophenyl hydrazine[4] The yield of product non-condensable at − 196° C was estimated by PVT measurement

The rate of formation of aldehyde, which may be assumed to be substantially propanal, was found to be $(3\ 5\pm0\ 5)\times10^{-6}$ moles/min The rate of formation of the "non-condensable" product was $(6\ 90\pm0\ 33)\times10^{-6}$ moles/min It can be assumed that the propanal yield is equal to the propene oxide yield Thus it can be concluded that the "non-condensable" product yield was substantially nitrogen and that all the $O(^3P)$ atoms produced during the photolysis reacted with the propene to form carbonyl and epoxide products

It has been shown that during gamma radiolysis of mixtures of carbon monoxide and propene when the propene content is less than 0 2 per cent, the yield ratios of carbonyl, epoxide and ketone products are similar to those found by Cvetanović[2] for the reaction of $O(^3P)$ with propene Furthermore, the yield of $O(^3P)$ atoms can be taken to be the sum of the product yields shown in Table 1—that is, $G[O(^3P)] = 1\ 41\pm0\ 22$, which accounts for about 75 per cent of the carbon dioxide yield

The mechanism of formation of the atoms and the electronic state in which they are initially formed are at present uncertain

Formation of $O_2(^1\Delta_g)$ in a Photochemical System involving Ozone

ELECTRONICALLY excited oxygen in the $^1\Delta_g$ state exists in the upper atmosphere, and a recent review[1] discusses several mechanisms for its formation Energy considerations alone suggest that the photochemical formation of $O_2(^1\Delta_g)$ involves absorption of the Sun's radiation by ozone[2] Singlet molecular oxygen in both $^1\Sigma_g^+$ and $^1\Delta_g$ states is known to react with ozone[3–5], so that the reactions of these species are probably of importance in atmospheric chemistry as well as being of considerable interest in studies of reaction kinetics Circumstantial evidence has accumulated which indicates that $O_2(^1\Delta_g)$ is produced on the photolysis of ozone[6,7] although direct observation of

$O_2(^1\Delta_g)$ has not hitherto been made in the photochemical system This communication describes the identification of $O_2(^1\Delta_g)$ by detection of the "infrared atmospheric" band of O_2 in emission at 1 27μ in a photochemical system involving ozone

The general technique of using a flow system to study low-level "photochemiluminescence" has previously been described[8] A reactant is irradiated in a part of the flow system upstream and optically isolated from the observation region. For the present experiments, three mercury resonance ($\lambda = 2537$ Å) lamps surrounded a quartz irradiation zone, and the observation chamber was a 5 l 'Pyrex' bulb with a gold reflecting layer evaporated onto its inside surface An RCA 7102 photomultiplier operated at −80° C was used as a radiation detector in conjunction with a chopper, amplifier and phase-sensitive detector to give good signal-noise discrimination Various wavelength bands could be isolated by means of narrow-band interference filters

Early experiments[8] on the ozone system were complicated by the observation of photochemiluminescence of the $NO + O_3$ reaction resulting from traces of N_2O_5 present in the ozone Extensive purification of the ozone reduces the $NO + O_3$ emission sufficiently to allow a small correction for it to be applied to any intensity observed at 1 27μ The ozone used usually contained less than 10 per cent oxygen as the only significant impurity. Radiation was observed at 1 27μ on photolysis of ozone to which molecular oxygen had been added. The emission did not appear on addition of nitrogen or argon, nor when oxygen was added after irradiation A search was made for radiation at 0 70μ, 0 76μ and 0 87μ, but no emission except that attributable to the weak residual $NO + O_3$ photochemiluminescence could be observed in any experiment Irradiation at $\lambda = 2537$ Å of molecular oxygen in the absence of ozone does not produce any detectable photochemiluminescent emission Fig 1 shows the variation of corrected intensity at 1 27μ with pressure of oxygen added at several typical ozone concentrations For some experimental conditions, the intensity observed at 1 27μ was more than 100 times that which could be accounted for by the residual $NO + O_3$ photochemiluminescence, and the emission is consistent with the production of $O_2(^1\Delta_g)$

The necessity of the presence of molecular oxygen for the appearance of the emission leads to certain conclusions about the mode of excitation of $O_2(^1\Delta_g)$ The primary photochemical process in the decomposition of ozone has often been suggested to be

$$O_3 + h\nu \rightarrow O_2(^1\Delta_g) + O(^1D) \quad (1)$$

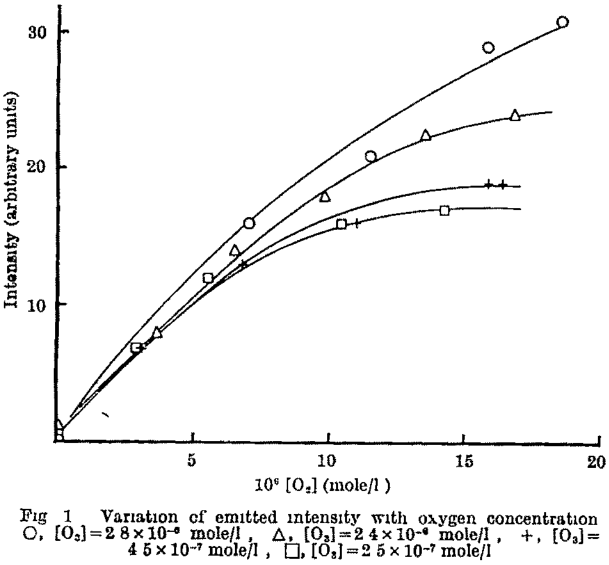

Fig 1 Variation of emitted intensity with oxygen concentration ○, $[O_3] = 2\ 8 \times 10^{-6}$ mole/l , △, $[O_3] = 2\ 4 \times 10^{-6}$ mole/l , +, $[O_3] = 4\ 5 \times 10^{-7}$ mole/l , □, $[O_3] = 2\ 5 \times 10^{-7}$ mole/l

Badger *et al* [9] have shown that the rate of spontaneous emission from $O_2(^1\Delta_g)$ is increased in the presence of molecular oxygen, although their results suggest that much greater pressures of oxygen than we employed would be necessary to give a marked enhancement of the transition probabilities An alternative explanation of the results is that the overall process represented by equation (1) is inefficient at the low pressures employed, and becomes more efficient with increasing pressure. Although there is some evidence in corroboration of this suggestion[10], addition of gases other than oxygen does not increase the observed emission intensity

A more plausible source of $O_2(^1\Delta_g)$ which is consistent with the results involves energy transfer in a secondary process It has been well substantiated that $O(^1D)$ is formed in the primary step in the photolysis of ozone, and one of the simplest excitation mechanisms for $O_2(^1\Delta_g^-)$ would be

$$O(^1D) + O_2(^3\Sigma_g^-) \rightarrow O_2(^1\Delta_g) + O(^3P) \quad (2)$$

as suggested by Vallance-Jones and Gattinger[11] for the formation of $O_2(^1\Delta_g)$ in the atmosphere Although the maximum concentration of $O(^1D)$ appears to lie at a considerably greater altitude in the atmosphere than the region from which the infrared atmospheric band originates, there is no reason to suppose that the rate of formation of $O_2(^1\Delta_g)$ will be greatest where the concentration of $O(^1D)$ is greatest Indeed, Bates[12] points out that at least one source of $O(^1D)$ in the atmosphere

$$3O(^3P) \rightarrow O_2 + O(^1D) \quad (3)$$

is likely to be most important at altitudes not inconsistent with those from which the atmospheric bands originate Because atomic oxygen persists in the atmosphere at night, either as ^1D or ^3P, the occurrence of reaction (2) would explain the observation of the infrared atmospheric band in the night airglow as well as in the dayglow

Young and Black[13] have reported an experiment involving the photolysis of oxygen at 1470 Å. Emission was observed at $\lambda = 0\ 76\mu$ and ascribed to $O_2(^1\Sigma_g^+)$ formed by the process

$$[O(^1D) + O_2(^3\Sigma_g^-) \rightarrow O_2(^1\Sigma_g^+) + O(^3P) \quad (4)$$

The rate of reaction (4) is important, because the reaction could account for the persistence of the atmospheric band at 0 76μ in the night airglow We did not observe emission from $O_2(^1\Sigma_g^+)$ in the ozone photolysis system, and consideration of the relative sensitivity of our apparatus for detection of $O_2(^1\Sigma_g^+)$ and $O_2(^1\Delta_g)$ suggests that reaction (4) is at least 10^4 times slower than reaction (2) if both reactions occur A kinetic study of the ozone photochemiluminescent system is being undertaken in order to attempt to elucidate further the excitation mechanisms, and to establish the efficiencies of reactions (2) and (4)

Complex Formations between Iso and Syndiotactic Polymethylmethacrylate in Solutions

LIQUORI[1,2] showed the occurrence of a possible "stereocomplex" in dissolved mixtures of iso and syndiotactic polymethylmethacrylate (PMMA) in a ratio of 1/2 i/s PMMA and, on the basis of X-ray diffraction on the solid mixtures, suggested its possible structure[1] After Liquori's first publication in 1965, we supposed that such a stereocomplex could also be shown by viscosity, light-scattering and refractive index measurements of solutions of isomer mixtures and by infrared spectral analysis of solid mixtures The syntheses of the iso and syndiotactic[3,4] isomers (I and S) are described in ref 5 The molecular weights and nuclear magnetic resonance tacticities are given in Table 1 The preparation of the solutions is described in ref 5 Chloroform is used as solvent

Table 1

PMMA	$\bar{M}_v$	Tacticity values[6] (Varian $A60$)				
		I	H	S	$\bar{n}_i$	$\bar{n}_s$
I	75,000	94	5	1	40	2
S	339,000	5	27	68	3	7

$\bar{M}_v$ is calculated from $[\eta] = 4\ 8 \times 10^{-5}\ \bar{M}_v^{0\ 8}$ (ref 3) where at 25° C $[\eta]$ is the intrinsic viscosity of solut ons in chloroform

From the viscosity measurements, made with a Ubbelohde viscosimeter, the reduced specific viscosity was calculated as

$$\eta^{\rm spec}_{\rm red} = (t_c - t_o)/t_o\ c\ ({\rm dl\ /g})$$

A Sofica 40,000 A was used to measure the light-scattering value V_v in mA, which is the intensity of the vertical polarized scattered light transmitted at right angles from a vertical polarized primary beam From the infrared spectra, registered with a Hitachi *EPI-G* after Goode[3], we calculated Goode's J-value for each mixture The refractive index measurements and measurements on other isomer mixtures are recorded in ref 5.

The curves in the graph clearly show an anomaly not only at the weight ratio 1/2 i/s PMMA mentioned by Liquori but also at the 2/1 i/s ratio Because the curve of the J-value (which is related to movement of the α-CH_3 groups) also shows inflexions at the same two ratios, these α-CH_3 groups must be involved in the complex conformations It is evident that the two special interactions appear independently of the isomer molecular weights or tacticities[5], and we expect the stereocomplexes not to be large structures We also proved[5] that the 21 Å interference in the X-ray spectra of the PMMA stereoisomers, used by Liquori[1] for structure calculation, is a parasitic one caused by a wavelength of the residual "white X-rays" These investigations lead us to doubt the structure and occurrence of one single stereocomplex proposed by Liquori Careful examination of the measured points in graph 2 of Liquori's second publication[2] indicates that he, too, measured, without recognition, both special interactions

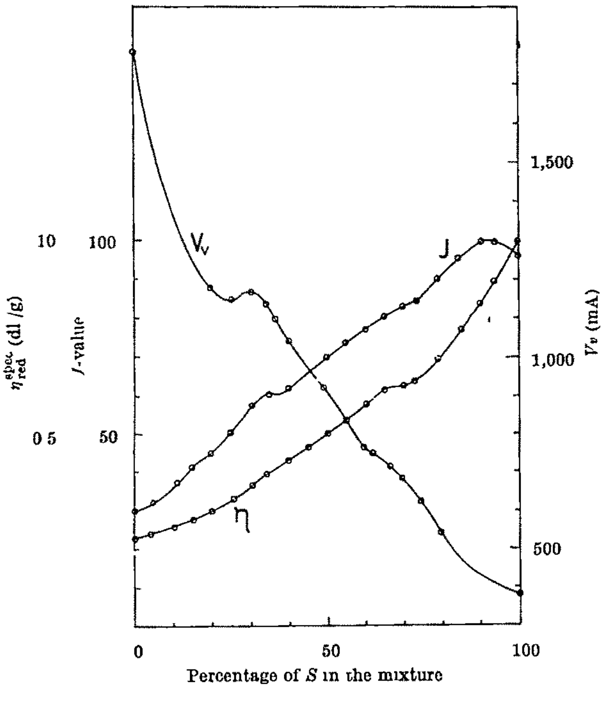

Fig 1 V_v, J-value and the reduced specific viscosity as a function of the weight percentage of the syndiotactic isomer in the mixtures Solution concentration 0 60000 g/dl

Stereoselective Interaction of Amino-acids and Metal Complexes

STEREOSELECTIVE effects frequently occur[1] in the formation and reactions of optically active co-ordination compounds The formation of ions of the type [Co(L-dipeptide)$_2$]$^-$ shows[2,3] very marked stereoselectivity which may be attributed to the three point attachment[4] of the dipeptide acting as a terdentate ligand, giving a puckered chelate ring Similarly, peptides of the type gly-Lα, α being an amino-acid, react[5] with the ion D[Coen$_2$(H_2O)(OH)]$^{2+}$ more rapidly than with its enantiomer, through three-point attachment. Related three-point attachment can also occur with amino-acids containing a polar side chain For example, we recently demonstrated[6] that L-glutamate ion reacts specifically with DL[Coen$_2$(H_2O)$_2$]$^{3+}$ giving D(+)[Coen$_2$(Lglu)]$^+$.

We report some stereoselective interactions of basic amino-acids with metal complexes of 1,2-diamine-tetra-acetate ions which probably also involve three-point bonding For example, resolution of the DL[Co(EDTA)]$^-$ ion is achieved when L-histidine is added to its acidic solution in aqueous ethanol The optically pure diastereoisomer [L-hisH_2] (+)$_{5461}$[CoEDTA]$_2$ 2H_2O crystallizes first Other Lα amino-acids with basic side chains (for example, L-arginine) can be used, although crystallization proceeds less readily [Co(PDTA)]$^-$ and other similar anions may also be resolved using L-histidine The present route provides a much simpler resolution of [Co(EDTA)]$^-$ than commonly used[7] which involves an initial resolution of a DL-*cis*-dinitrobisethylenediaminecobalt(III) salt DL-Histidine may also be resolved by using its diastereoisomeric salts with (+) or (−) [CoEDTA]$^-$

Related to this convenient new resolution is a novel resolution of lysine using [Co(EDTA)]$^-$ or the *trans*-1,2-diaminocyclohexane-*NNN′N′*-tetra-acetatocobaltate(III) anion When a solution of dodecatungstophosphoric acid is slowly added to a concentrated solution of K (−)$_{5461}$ [Co(EDTA)] (1 mole) and DL-lysine hydrochloride (2 moles), the initial precipitate is the tungstophosphate of

D-lysine If sufficient dodecatungstophosphoric acid is added, then its L-lysine salt is eventually precipitated

BIOCHEMISTRY

Relationship between Concentrations of Human Chorionic Gonadotrophin in Plasma and Cerebrospinal Fluid

Human chorionic gonadotrophin (HCG) has been detected by various bioassay procedures in the cerebrospinal fluid of pregnant and non-pregnant subjects with a high concentration of the hormone in the plasma and urine[1-5] It was not detected in the cerebrospinal fluid when the plasma and urine concentrations were lower In agreement with these earlier workers, McCormick[6] and Tashima *et al* [7] concluded that HCG did not appear in the cerebrospinal fluid until a high threshold value, equivalent to a urinary excretion rate of about 250,000 IU of HCG/day, was exceeded

The opportunity to obtain cerebrospinal fluid during normal pregnancy rarely arises, but patients with trophoblastic tumours also have HCG in their body fluids and this permits study of the plasma–cerebrospinal fluid relationship for this hormone We report here radioimmunoassay estimates of corresponding concentrations of HCG of plasma and cerebrospinal fluid in twelve subjects who had trophoblastic tumours but who did not have any evidence of metastases in the central nervous system The observations indicate that for a thousand-fold range of concentrations there is no evidence of a threshold effect and that the concentration of HCG in the cerebrospinal fluid, determined immunologically, is directly proportional to that in the plasma

Details of the radioimmunoassay have been described earlier[8-10] Both HCG and luteinizing hormone (LH) are estimated and approximately 1 ml of the sample fluid is required Twenty-four hour urine samples were collected with merthiolate (100 mg) as a preservative Cerebrospinal fluid obtained by lumbar puncture was stored at − 15° C without anticoagulant or preservative Plasma samples were collected at the time of lumbar puncture with 2 mg/ml of ethylenediamine tetraacetic acid (EDTA) as anticoagulant

Gonadotrophic activity was not detectable in the cerebrospinal fluid of ten hospital patients with normal plasma concentrations of LH who underwent lumbar puncture in the course of investigations for various complaints Total cerebrospinal fluid protein concentrations of the patients with choriocarcinoma were determined by a turbidometric method using sulphosalicylic acid, and all were normal ($<$ 40 mg/100 ml) The corresponding concentrations of HCG in plasma and cerebrospinal fluid are shown in Table 1 and are plotted on a double logarithmic scale in Fig 1 The log HCG cerebrospinal fluid and log HCG plasma are significantly correlated ($P < 0$ 001—two-sided tests) and the data are adequately represented by the simple relationship concentration of HCG in cerebrospinal fluid = 0 0057 × concentration of HCG in plasma The results demonstrate a close correlation between the concentrations of HCG in plasma and cerebrospinal fluid, determined immunologically, for a range of plasma concentrations of 0 28–280 IU/ml

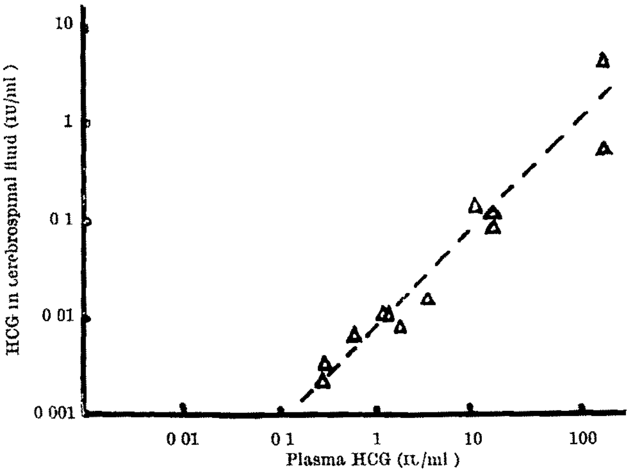

Fig 1 Relationship between concentration of HCG in plasma and spinal fluid

Table 1 CONCENTRATIONS OF HCG IN PLASMA AND CEREBROSPINAL FLUID OF PATIENTS WITH TROPHOBLASTIC TUMOURS

Case No	HCG (IU/ml)		Plasma/
	Plasma	Cerebrospinal fluid	Cerebrospinal fluid
69	0 320	0 003	106

169	0 700	0 006	117
191	270 000	0 450	600
193	3 620	0 015	240

The discrepancy between our findings and the suggestion, from results of bioassay studies, that a threshold effect limits the entry of HCG into the cerebrospinal fluid at low plasma concentrations could be accounted for if much of the HCG entering the cerebrospinal fluid lost its biological but not its immunological activity It is known that the biological activity of HCG can be lost without a parallel loss of immunological activity as a result of heating or exposure to neuraminidase which modifies the charge of the molecule (unpublished work of Wilde, Orr and Bagshawe) We have, however, no evidence that degradation occurs in the cerebrospinal fluid or that there is selective transport of immunologically active, biologically inert molecules The mean plasma cerebrospinal fluid ratio of 177 1 found by radioimmunoassay in this work can be compared with a ratio of 187 1 obtained by bioassay[6] after HCG was infused into a nephrectomized dog It is also clear that the bioassay procedures used were too insensitive to detect the small amount of HCG present in the cerebrospinal fluid when the plasma concentration was relatively low and the proposition of a threshold effect may be attributed to failure to recognize fully the consequences of this insensitivity

The relatively low concentration of HCG in the cerebrospinal fluid is typical of proteins in general[12], and if equilibration between the compartments is slow, rapid changes in the plasma concentration will not be reflected promptly in the cerebrospinal fluid concentration The presence of HCG producing tumours in the central nervous system may also disturb the plasma cerebrospinal fluid ratio and observations on patients with intracranial metastases will be reported later

Although differences between HCG produced by tumours and the normal placenta have been suspected[13], these have not been confirmed by later work[14,15], and we have found no reports of a disturbance of plasma–cerebrospinal fluid transport in normal pregnancy or in patients with trophoblastic tumours outside the central nervous system On present evidence it therefore seems likely that the plasma cerebrospinal fluid relationship for HCG reported here also obtains in normal pregnancy

We are not aware that similar plasma–cerebrospinal fluid relationships have been established for any other substance, although it may also apply to insulin Margolis and Altszuler[16] have recently examined the concentration of insulin in plasma and cerebrospinal fluid by radioimmunoassay during insulin infusion in the dog When their data are plotted on a double logarithmic scale a similar linear relationship is seen between the concentrations of this hormone in plasma and cerebrospinal fluid

Glycogen Synthetase Activity in Blood Platelets

Leloir *et al*[1-3] found the key enzyme in glycogen synthesis to be UDP glucose α1-4 glucan-4-glucosyl transferase (E C 2 4 1 11), also called glycogen synthetase The enzyme has been extensively studied in liver[1-3] and muscle[4,5], and has been identified in blood leucocytes[6]

The results presented here indicate that pig blood platelets have a significant glycogen synthetase activity, and some general properties of the crude enzyme are reported

Pig blood was collected on acid citrate dextrose medium (B formula of the National Institutes of Health) and maintained at 0° C until the platelets had been separated The blood was centrifuged at 1,200 r p m for 10 min in an International PR_2 refrigerated centrifuge (rotor No 259), the plasma was collected and run at 2,300 r p m for 5 min and the supernatant was used as a source of platelets which were isolated by centrifugation at 15,000 r p m for 20 min in a refrigerated Sorvall centrifuge (rotor *SS* 34) The platelets were washed three times in saline to which was added 1 mM versene, *p*H 7 5 The final pellet was resuspended in twice distilled water or in a medium made up of 1 mM *tris*, *p*H 7 5, 0 25 M sucrose and 1 mM versene, *p*H 7 5 All the centrifugations were performed with plastic tubes Examination of the platelet suspension by phase contrast microscopy indicated that no aggregation had occurred during preparation The homogenate was prepared by treating the platelet suspension in a tissue grinder fitted with a rotating 'Teflon' pestle for 5 min at 0° C

Glycogen synthetase activity was measured by a method similar to that described by De Wulf and Hers[7], and the amount of radioactivity incorporated into glycogen from UDP-glucose labelled with carbon-14 was determined The assay mixture contained 2 mg of shellfish glycogen, 0 2 μmole of UDP-glucose, 5,000–6,000 c p m of ^{14}C-UDP-glucose (Radiochemical Centre, Amersham) and 4 μmoles of glycylglycine, *p*H 8 4, in some cases, 0 5 μmoles of glucose-6-phosphate was added in a volume of 0 05 ml The reaction was initiated by adding 0 1 ml of homogenate, the mixture was incubated at 37° C, and the reaction was stopped by the addition of 0 5 ml of cold 10 per cent TCA A volume (0 05 ml) of a 10 per cent glycogen solution was then added and the total glycogen precipitated and collected in the way described by De Wulf and Hers[7] Radioactive samples (0 5 ml) from the various tests were added to vials containing 10 per cent naphthalene, 1 per cent 2,5-diphenyloxazole, 0 025 per cent 1,4-*bis*-2-(5-phenyloxazolyl) benzene and 20 per cent ethanol in dioxan, and the radioactivity was then counted in a Nuclear Chicago liquid scintillation counter Glycogen was determined by the anthrone method[8] and proteins were measured by the method of Lowry *et al* [9]

Homogenates of pig blood platelets can catalyse the incorporation of radioactivity from ^{14}C-UDP-glucose into glycogen Within certain limits, the reaction is linearly proportional to the amount of homogenate (Fig 1) and to the time of incubation (Fig 2) Addition of glucose-6-phosphate greatly increases the enzyme activity (Figs 1 and 2) At a concentration 3 3 mM, a three to six-fold increase has been observed in different preparations Half the maximal activation is obtained with a concentration of glucose-6-phosphate of about 0 8 mM

Fig 3 illustrates the effect of changing the concentration of UDP-glucose The K_m value in the presence of glucose-6-phosphate is $5\ 5 \times 10^{-4}$ M The sugar phosphate

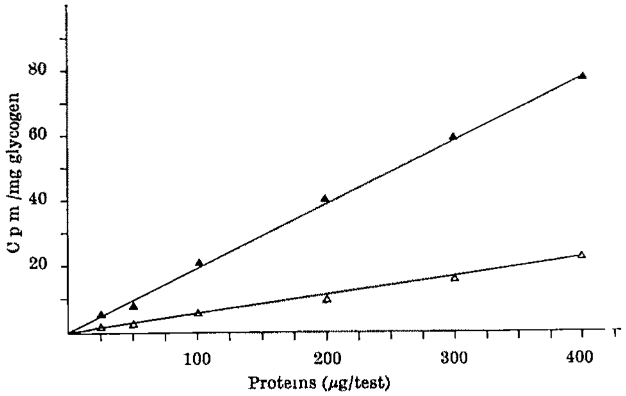

Fig 1 Dependence of the reaction rate of glycogen synthetase on enzyme concentration The amount of enzyme preparation added was varied as indicated The assay mixture was incubated for 20 min at 37° C without glucose-6-phosphate (△—△) or in the presence of 0 5 μmoles of glucose-6-phosphate (▲—▲)

causes a striking increase in the V value but does not considerably affect the K_m value for UDP-glucose The optimum *p*H for the platelet enzyme was found to be about 8 5 in the presence of glucose-6-phosphate Glycogen synthetase of pig blood platelets is chiefly associated with structure sedimenting at high speed in 0 25 M sucrose The enzyme is purified seven to nine-fold in the sediment obtained by centrifugation of the homogenates at 105,000*g* for 60 min Homogenates of pig platelets maintained at 0° C or at – 20° C retain their glycogen synthetase activity for at least 1 month without any significant change, purified preparations obtained by centrifugation (105,000*g* pellet) are less stable and lose a significant part of their activity after 24 h at 0° C or at – 20° C

Mercaptoethanol at a concentration of 0 05 M stimulates the total activity of the enzyme Table 1 shows the results obtained on a partially purified enzyme (105,000*g* pellet) The thiocompound significantly increases the activity of the enzyme when tested in the presence of glucose-6-phosphate, but the effect is less marked in the absence of the sugar phosphate Preincubation of the preparation for 60 min at 30° C in the presence of mercaptoethanol does not significantly change the effect of the compound

Table 1 EFFECT OF MERCAPTOETHANOL ON THE GLYCOGEN SYNTHETASE ACTIVITY OF BLOOD PLATELETS

Preincubation time (min)	C p m /mg glycogen With glucose-6-phosphate		Without glucose-6-phosphate	
	– M–SH	+ M–SH	– M–SH	+ M–SH
0	142	183	40	44
60	127	178	36	43

0 1 ml of enzyme (105,000*g* pellet) containing 1 36 mg of protein is preincubated at 30° C for 0 or 60 min in the presence or absence of 5×10^{-3} M mercaptoethanol (M–SH) The assays are then performed with or without the addition of 3 3 mM glucose-6-phosphate for 20 min

The general properties of the glycogen synthetase in pig blood platelets are comparable with those of glycogen synthetase found in other tissues, in particular with liver and muscle enzymes[1-4] As with these enzymes, UDP-glucose-transglucosylase activity in pig blood platelets is at least partially dependent on the presence of glucose-6-phosphate, its optimum *p*H is slightly alkaline and the K_m value for UDP-glucose is comparable with that found by Leloir and Goldemberg[3] for crude preparations of liver and muscle Moreover, after centrifugation the platelet enzyme is chiefly recovered in a 105,000*g* pellet with which the platelet glycogen is probably associated

Rosell-Perez and Larner using a dog muscle preparation[10] have found that mercaptoethanol promotes the conversion of glycogen synthetase from a form which is dependent on glucose-6-phosphate to a form independent of that compound On the other hand, according to these authors, total activity of glycogen synthetase of frog and toadfish muscle is stimulated by mercaptoethanol in the presence of glucose-6-phosphate without conversion from one form to another The platelet enzyme behaves in the same way, total activity being increased by the thiocompound without any apparent conversion of the enzyme

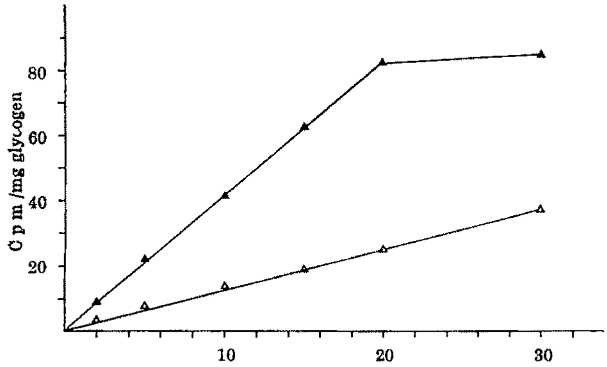

Fig 2 Time course of the glycogen synthetase reaction The times were as indicated The tests were performed at 37° C with 0 1 ml of a homogenate containing 5 mg of protein/ml without glucose-6-phosphate (△—△) or in the presence of 0 5 μmoles of glucose-6-phosphate (▲—▲)

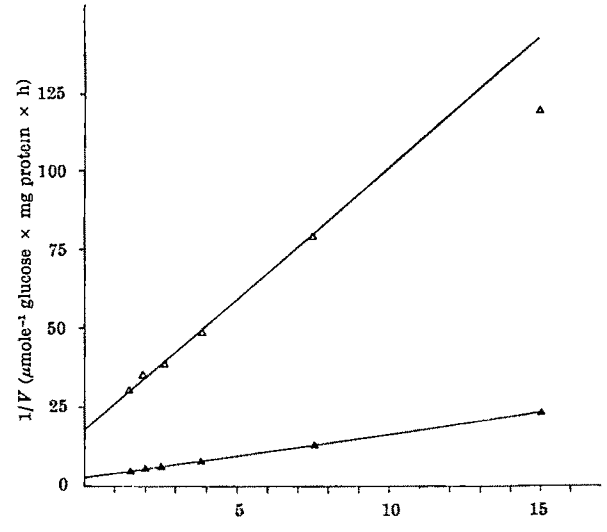

Fig 3 Reciprocal plot of the dependence of UDP-glucose concentration on thrombocyte glycogen synthetase without glucose-6-phosphate (△—△) or in the presence of 0 5 μmoles of glucose-6-phosphate (▲—▲) The tests were performed with 0 1 ml of a homogenate containing 5 mg of protein/ml

Glycogen seems to be one of the principal energetic materials of thrombocytes[11] The enzymes involved in its metabolism are thus of particular interest with respect to the general metabolism of blood platelets Most of the enzymes of glycolysis[11] and phosphorylase[12] have been identified in these blood constituents Our results show that thrombocytes can also synthesize their own glycogen and do not depend completely on glycogen obtained from the megakaryocytes

Formation of Melatonin and 5-Hydroxyindole Acetic Acid from ^{14}C-Tryptophan by Rat Pineal Glands in Organ Culture

THE rat pineal gland contains large amounts of serotonin[1] and the enzymes tryptophan hydroxylase[2] and aromatic l-amino-acid decarboxylase[3] which synthesize this indoleamine from tryptophan. We have reported that rat pineals in organ culture retain the ability to produce serotonin from its amino-acid precursors tryptophan and 5-hydroxytryptophan[4]. Most of the serotonin normally formed in the pineal is oxidized to 5-hydroxyindole acetic acid[5] by the enzymes monoamine oxidase[6] and aldehyde dehydrogenase. In addition, a portion of the indoleamine is *N*-acetylated[7] and then converted to melatonin by hydroxyindole-*O*-methyl transferase[8], an enzyme present in mammals only in the pineal gland[9]. By using isotopically labelled tryptophan as the substrate for our organ culture system, we have observed that such preparations can transform the serotonin produced to two end products: 5-hydroxyindole acetic acid (5HIAA) and melatonin.

Sprague–Dawley female rats weighing 160–180 g each were killed by neck fracture, and their pineal glands were removed and clotted to the walls of a Wasserman tube as described before[4]. Nutrient medium (0.5 ml)[4] containing ^{14}C-tryptophan or ^{14}C-5-hydroxytryptophan was added, and the tubes were sealed with a rubber stopper and incubated for 2 days at 37° C. Control cultures were frozen immediately after the addition of the nutrient medium or were incubated without a pineal gland. At the end of the incubation period, the media were frozen, samples were then assayed for their contents of total radioactivity, ^{14}C-serotonin, ^{14}C-melatonin and ^{14}C-5HIAA as follows. A 0.1 ml sample of the medium was transferred to a glass-stoppered centrifuge tube containing 2 ml of 0·1 M borate buffer, *p*H 10, and the ^{14}C-melatonin was extracted into 6 ml of chloroform. After centrifugation, a 1 ml sample of the aqueous phase was transferred to a second glass-stoppered centrifuge tube and the ^{14}C-serotonin was extracted into 6 ml of a mixture of butanol and chloroform (1 : 3). The rest of the aqueous phase in the first tube was removed by suction. The chloroform was washed with 2 ml of borate buffer, *p*H 10, and 4 ml was transferred to a counting vial and evaporated. The radioactivity was measured in a liquid scintillation spectrophotometer after the addition of phosphor. The chloroform-extractable radioactivity was identified as ^{14}C-melatonin by chromatography in three systems (ascending paper chromatography, butanol : acetic acid : water, 8 : 2 : 2; ascending paper chromatography, isopropanol : ammonium hydroxide : water, 8 : 2 : 2; thin-layer chromatography, chloroform : methanol, 94 : 6). The butanol : chloroform mixture in the second centrifuge tube was washed with 2 ml of borate buffer, *p*H 10, and 4 ml. of the washed mixture was transferred to a vial and evaporated; its radioactivity was counted after the addition of phosphor. This radioactive material was identified as ^{14}C-serotonin using the chromatographic systems already described. A further 0.1 ml of the culture medium was transferred to a glass-stoppered centrifuge tube containing 1 ml of 0.2 M hydrochloric acid and the ^{14}C-5HIAA was extracted into 6 ml of ethyl ether. The ether layer was transferred to another centrifuge tube, and the 5HIAA was re-extracted into 2 ml of 0.1 M buffer, *p*H 7.9. The ether layer was removed by suction, and the aqueous layer was shaken again with 6 ml of ether. The ether layer was discarded, the aqueous layer was acidified with 1 ml of 1.0 M hydrochloric acid, and the radioactivity was re-extracted into a final 6 ml of ether. A 4 ml sample of the organic phase was transferred to a vial and evaporated to dryness; its radioactivity was measured after the addition of phosphor. The radioactive material was shown to be ^{14}C-5HIAA, using the chromatographic system already described. The recoveries of serotonin, melatonin and 5HIAA were approximately 80 per cent, 90 per cent, and 50 per cent, respectively, and were relatively constant from experiment to experiment. The sum of the labelled serotonin, melatonin and 5HIAA extracted from each culture tube was taken as an estimate of the total amount of serotonin produced in that tube. Each treatment group contained four culture tubes.

Pineal organs were incubated with ^{14}C-tryptophan (10^{-4} M, 460,000 c.p.m.) or ^{14}C-5-hydroxytryptophan (2.5×10^{-4} M, 460,000 c.p.m.) for 2 days. The culture tubes were held stationary or were rotated in a roller wheel.

In all conditions studied, considerable amounts of serotonin, melatonin and 5HIAA were formed. The mean synthesis of each indole from ^{14}C-tryptophan in roller tubes was similar in four separate experiments. When tryptophan was used as the substrate, rotation was associated with an increase both in the total serotonin formed and in its conversion to 5HIAA. Pineals in stationary tubes transformed 0.81 ± 0.07 per cent of the ^{14}C-tryptophan into its three indole metabolites. Similar organs in roller tubes converted 2.03 ± 0.17 per cent of the amino-acid to serotonin, melatonin or 5HIAA. Most of this difference was represented in the serotonin and 5HIAA fractions; the concentrations of ^{14}C-melatonin in the media did not differ between groups of stationary and rotated tubes (Table 1). When pineals were incubated with ^{14}C-5-hydroxytryptophan instead of tryptophan, the total ^{14}C-serotonin formed was not increased by rotating the culture tubes: 2.01 ± 0.21 per cent of the radioactivity in the media from stationary cultures was serotonin, melatonin or 5HIAA, as compared with 2.24 ± 0.22 per cent in the media from roller tubes. The formation of ^{14}C-5HIAA, however, was significantly enhanced in the roller tubes (Table 1). These results indicate that the metabolism of tryptophan by rat pineal glands in organ culture proceeds as follows:

$$\begin{tikzcd} & & & \text{melatonin} \\ \text{tryptophan} \arrow[r] & \text{5-hydroxytryptophan} \arrow[r] & \text{serotonin} \arrow[ur] \arrow[dr] & \\ & & & \text{5HIAA} \end{tikzcd}$$

The formation of serotonin from tryptophan (but not from 5-hydroxytryptophan) involves the action of an oxidative enzyme, tryptophan hydroxylase. Similarly, the production of 5HIAA (but not melatonin) from serotonin involves successive oxidations of the amine to an aldehyde and then to an acid. Only those three of the foregoing reactions which involve the action of oxidative enzymes were suppressed by stationary incubation (Table 1). In striking contrast, the remaining three enzyme reactions which do not involve oxidation proceeded at the same rate in both stationary and rolling cultures. Thus the most likely explanation for increased synthesis of serotonin and 5HIAA (but not melatonin) in the roller tubes is that rotation makes more oxygen available to the cells, thereby facilitating the actions of the oxidative enzymes but not altering the rates of the non-oxidative reactions.

The metabolism of pineal indoles is influenced by the activity of the sympathetic nerves to the pineal[10]. The development of an *in vitro* system in which all the pineal enzymes involved in indole metabolism remain operative should facilitate studies on the biochemical mechanisms

Table 1. BIOSYNTHESIS OF SEROTONIN, MELATONIN AND 5HIAA FROM ^{14}C-AMINO-ACIDS BY RAT PINEAL GLANDS IN ORGAN CULTURE

Substrate	Tubes rotated	^{14}C-Serotonin	^{14}C-Melatonin	^{14}C-5HIAA	Total
^{14}C-Tryptophan	No	0.17	0.23	0.41	0.81
	Yes	0.74*	0.27	1.02*	2.03*
^{14}C-5-Hydroxytryptophan	No	0.99	0.29	0.73	2.01
	Yes	0.65	0.19	1.40*	2.24

Groups of four culture tubes each containing a single rat pineal were incubated with ^{14}C-tryptophan (10^{-4} M, 460,000 c.p.m.) or ^{14}C-5-hydroxytryptophan (2.5×10^{-4} M, 460,000 c.p.m.) for 2 days at 37° C.

* $P < 0.01$ differs from stationary group.

by which nerve impulses control pineal parenchymal function This system might also provide a relatively simple mechanism for testing the effects of drugs and hormones on the biosynthesis of serotonin and related compounds

MICROBIOLOGY

Enzootic Rabies in Rodents in Thailand

RABIES virus has occasionally been isolated from feral rats[1] and yet rodents are not considered to be a significant reservoir of sylvatic rabies[2] These conclusions are based on negative results of surveys of small mammal species in areas in which rabies is endemic[2,3] The isolation of rabies virus from a field rat, *Bandicoota indicus*, in the course of routine diagnostic procedures prompted a survey of several small mammals in Thailand, a country where rabies is endemic When it was certain that the virus was present in a number of *Bandicoota indicus*, it then became important to determine whether overt disease occurred and if virus was being transmitted as an inapparent infection in the species The results of the survey and preliminary data on the epidemiology of rabies in *Bandicoota indicus* are the subject of this report

Rodents and other small mammals were trapped in rural farm and forest areas and around small towns in central and south-eastern provinces of Thailand between August 1 and December 31, 1966 The animals were identified, their heads were removed, frozen in dry ice and shipped to the laboratory Initially only *B indicus* and *B bengalensis* were retained for examination, but later all trapped animals were tested for rabies

The fluorescent antibody technique (FAT) as described by Goldwasser and Kissling[4] was utilized with slight modifications to make the initial diagnoses The modifications consisted of the use of a commercially prepared anti-rabies fluorescein dye conjugate, equine origin (Baltimore Biological Laboratories), and rhodamine in a 1 100 dilution as a background stain[5]

Positive control slides, interspersed among the survey samples, were prepared from weanling mice which had been inoculated with street virus FAT positive specimens were confirmed by intracranial inoculation of weanling mice Most specimens negative by FAT were discarded without further testing, but a few were inoculated along with the FAT positive specimen

Homogenates of brain tissue from all specimens giving a positive fluorescent antibody test and selected specimens giving a negative reaction (10–20 per cent brain suspension in buffered saline, pH 7 2, prepared using a Ten Broeck tissue homogenizer) were each inoculated intracranially into six weanling white mice (0 3 ml per mouse) Mice were observed daily for symptoms of rabies Animals showing terminal signs of rabies were killed and examined by the fluorescent antibody test

One isolate from each species was identified in a serum neutralization test Serial ten-fold dilutions of the isolate (2×10^{-1}–2×10^{-8}) were prepared from first passage mouse brain Dilutions of virus (0 5 ml per dilution) were then incubated with an equal volume of hyperimmune equine anti-rabies serum (Lederle) or with normal horse serum for 1 h at 37° C The serum–virus mixtures were then inoculated intracranially into weanling mice (0 03 ml per mouse) The mice were observed daily for 28 days for signs of rabies

For the susceptibility tests ten immature bandicoot rats were inoculated intramuscularly in the quadriceps region and subcutaneously in the neck region (0 05 ml per site) with a 20 per cent suspension which consisted of a composite of all the bandicoot isolates after first mouse brain passage The suspension contained $10^{6\ 6}$ weanling mouse LD_{50}/0 03 ml as computed by the Reed–Muench method[6] Inoculated animals were caged individually and observed daily for symptoms of rabies Those found dead or killed when moribund were examined by the fluorescent antibody test and mouse inoculation tests to confirm the cause of death

Rabies virus was isolated from several species of wild rodents as shown in Table 1 The percentage of positive cases was highest in *B indicus* Ten of the 126 examined (7 9 per cent) were positive both to the fluorescent antibody test and to mouse inoculation Only seven of 375 (1 9 per cent) *B bengalensis*, a closely related species, were found to be positive

All isolates were confirmed by mouse inoculation Mice injected intracranially with suspensions from brains which gave a positive fluorescent antibody test usually began to show symptoms of rabies 10–14 days after inoculation Symptoms and death rarely occurred between 5 and 10 days One hundred and fifteen specimens negative to the test were confirmed by mouse inoculation (M I) Several negative specimens were included with each group of positives There was 100 per cent correlation between the fluorescent antibody test and mouse inoculations Hyperimmune equine anti-rabies serum had a log neutralization index of 3 0 or greater when tested against isolates from each species

Table 2 shows the results of susceptibility tests Five of the ten rats injected parenterally with the homologous virus isolate died, and four showed typical symptoms of rabies There was an average incubation period of 20 6 days and a range of 14–33 days One apparently normal rat was killed 78 days after inoculation and virus was

isolated from both brain and salivary gland One rat killed after 113 days and three after 212 days after inoculation were negative to both FAT and M I

The well known century cyclic nature of rabies raises the important question Why does the incidence increase dramatically in endemic areas ? WHO experts suggest that the answer must lie in the wildlife reservoir The information reported here and the studies by Svet-Moldavskaya[7] indicate that rabies virus infections may be chronic or inapparent in some species of rats The fact that one apparently healthy rat was shown to have rabies virus in the brain and salivary glands 78 days after inoculation suggests that inapparent infections can occur naturally

The high percentage of rabies positive specimens in *B indicus* is surprising The possibility that the occurrence of rabies in the rodent population results from exposure to stray dogs and cats in an area where the disease incidence is high cannot be dismissed Another possible means of introduction of the disease into the rat population might be from fruit and insectivorous bats in the area Their close proximity in natural habitats such as temples, caves and heavily forested areas lends credence to this suggestion The incidence of rabies in some species of bats in certain areas of Thailand has been shown to be as high as 3 per cent[8] The oral route in infected tissue or food must also be considered according to a recent report by Soave[9]

Rabies has been diagnosed in six different species of rodents in Thailand Approximately 8 per cent of *Bandicoota indicus* tested were positive, but the percentage was much lower in other species of wild rodents Thirty-seven of 1,037 specimens of rodents or other small mammals were examined and found to be positive A preliminary experiment revealed that one apparently healthy *B indicus* killed 78 days after inoculation with a massive dose of rabies virus had virus in brain and salivary tissue The evidence presented here suggests that the bandicoot rat may be an inapparent carrier of rabies virus infections Rabies virus was also isolated from two of thirty common house shrews, *Suncus murinus*

Genetics and Cultural Properties of Mutants of *Salmonella typhimurium* lacking Glucosyl or Galactosyl Lipopolysaccharide Transferases

THE somatic (0) lipopolysaccharide of smooth salmonella strains contains an inner part or core, believed to be the same in all species, this consists of a heptose-containing "backbone", with short side-chains which contain glucose, galactose and *N*-acetylglucosamine and are thought to have the structure shown in Fig 1 (ref 1) The outer, O-specific part of lipopolysaccharide (absent in rough strains) is made up of many repeat units of an oligosaccharide the composition of which determines the O antigens of the strain These O-specific chains are probably attached to the distal ends of the core side-chains This and the following communication describe mutants in glycosyl-transferring enzymes concerned in the biosynthesis of the side-chains of the core

Mutants lacking the enzyme UDP-galactose-4-epimerase are unable (in the absence of exogenous galactose) to syn-

thesize UDP-galactose, the donor of the galactose components of lipopolysaccharide, and so they make a polysaccharide with incomplete core side-chains, lacking the galactose units and all the sugars which normally lie distal to them[2,3] When UDP-galactose is added to a broken-cell preparation of such a mutant, galactose is transferred to the lipopolysaccharide[4,5] We thought that mutants lacking the enzyme or enzymes which effect this transfer would make lipopolysaccharide similar to that of the galactose-epimerase-negative mutants Such transferase-negative mutants would, however, retain the wild-type ability to ferment galactose, which ability, because it involves the epimerization of UDP-galactose to UDP-glucose, is absent in epimerase-negative mutants We found that galactose-epimerase-negative mutants of *S typhimurium* strain *LT*2 had a distinctive pattern of resistance and susceptibility to a battery of smooth-specific and rough-specific phages—which, presumably, utilize lipopolysaccharide as their site of adsorption to the bacteria (Table 1) Unlike other non-smooth mutants, including *rouA* (=*rfa*) and *rouB* (=*rfb*) mutants[6] and semi-rough mutants of classes *C* and *D* (ref 7), they were sensitive to phage *C*21, which in *Escherichia coli* strain *K*12 attacks only mutants unable to synthesize UDP-galactose or UDP-glucose[8] We therefore looked for *LT*2 mutants which were sensitive to phage *C*21 but able to ferment galactose, in the expectation that they would be galactosyl-transferase-negative In some experiments we used as parent strains *TV*119 and *TV*149, *LT*2 mutants of the type *rouB* (=*rfb*) which cannot synthesize the O-specific distal part of the side-chain and are sensitive to Felix anti-O phage[9] and to the rough-specific phage 6*SR* (ref 10), neither of which attacks galactose-epimerase mutants Among spontaneous mutants selected for resistance to a mixture of these two phages, we encountered four which were *C*21-sensitive but galactose-fermenting We also attempted to isolate mutants of this sort from a genetically marked *LT*2 smooth line, *SL*1027, of genotype *metA trpB H*1-*b H*2-*e,n,x fla str xyl*, and from two phosphomannose-isomerase-negative (*pmi*) mutants of it Mutants of the latter class make incomplete lipopolysaccharides unless grown with exogenous mannose[11], the *pmi* mutants were grown on mannose-supplemented medium The phenotypically smooth cultures were exposed to a mixture of virulent phages comprising *P*22*c*$_2$ (ref 12), which attacks only smooth cultures, Felix O phage and, in some experiments, the rough-specific phage 6*SR* Six *C*21-sensitive galactose-fermenting mutants were thus obtained The cultural and phage-resistance properties of these presumed galactosyl-transferase-negative mutants were tested on mannose-supplemented media in the case of strains lacking phosphomannose isomerase All ten strains had some of the cultural properties of rough mutants they grew in broth as a deposit, leaving a clear supernatant fluid and agglutinated in 0 9 per cent, but not 0 2 per cent, sodium chloride Such suspensions were not agglutinated by undiluted anti-04 antiserum in slide tests Their pattern of susceptibility to phages divided the mutants into two classes (Table 1) All resembled galactose-epimerase mutants in that they were resistant to the smooth-specific phage *P*22 and to 9*NA* (a smooth-specific phage serologically and otherwise unrelated to *P*22, personal communication from P Gemski), resistant to the rough-specific phages 6*SR* and φ*X*-174, but sensitive to *C*21 and to the rough-specific phages *P*221 (ref 13) *Ffm* (ref 14) and *Br*60 (phage 60 of Brandis[15]) Eight mutants were completely resistant to Felix O phage and to the rough-specific phage *Br*2 (phage 2 of Brandis[15]) which attacks epimerase mutants The other two mutants, *SL*1033 and *SL*1060, were sensitive to *Br*2, *SL*1060 was completely resistant, *SL*1030 partly resistant, to Felix O phage

Biochemical examination of the ten mutants by Dr M J Osborn (see following communication) showed that the two mutants sensitive to phage *Br*2 as expected lacked a galactosyl transferase, but that the eight mutants resistant to phage *Br*2 had normal galactosyl transferase activity, they instead lacked the enzyme which transfers to glucose-deficient lipopolysaccharide the glucose unit which lies proximal to the galactose units of the core side-chains The sugar composition of the lipopolysaccharide from the two classes of mutant and their abilities to accept glucose or galactose in the presence of extracts of wild-type cells confirmed these conclusions

To map the mutated loci of the glucosyl and galactosyl transferase mutants, we mated some of them with smooth Hfr sublines of *LT*2 (ref 16) Recombinants from various selections after purification were scored for all segregating characters, their glycosyl transferase character being inferred from their sensitivity to appropriate phages, phage-pattern always segregated as though determined by a single locus The glucosyl transferase mutant *SL*1032 was first mated to *LT*2 Hfr*A* (ref 17) which injects its chromosome clockwise, with *ile* as the leading locus (Fig 2) None of the seventy recombinants selected for possession of the donor marker *trpB*$^+$ had the smooth character of the Hfr parent We infer that the glucosyl transferase locus does not lie between the point of origin of this Hfr and the last donor locus represented, *his* We then used Hfr*B*2 (ref 16) which injects clockwise from a

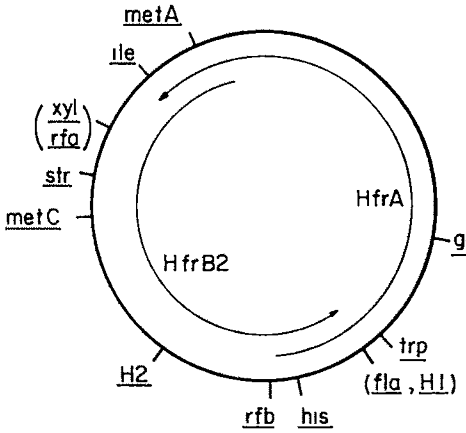

Fig 2 Linkage map of *S typhimurium* (distances approximate) and Hfr donors used, with their points of entry and approximate extents of chromosome transfer (loci bracketed, order unknown) *met*, *trp*, *his*, *ile*, Requirement for methionine, tryptophan, histidine, isoleucine, *gal*, *xyl*, fermentation of galactose, xylose, *fla*, flagellation, *H*1, *H*2, phase-1 and phase-2 flagellar antigens, *str*, streptomycin-resistance, *rfb* (=*rouB* of ref 6), defect in biosynthesis of O-specific part of lipopolysaccharide, *rfa* (=*rouA* of ref 6, and *rfaG* and *rfaH* of this communication), defect in synthesis of lipopolysaccharide core

point between *trp* and *fla* In the cross Hfr*B*2→*SL*1032 more than 85 per cent of recombinants selected for acquisition of the donor *metA*$^+$ and more than 85 per cent of those selected for possession of the donor *xyl*$^+$ had the smooth character of the donor, and were completely resistant to phage *C*21 and the other rough-specific phages active on *SL*1032 Analysis of the number of crossovers required to account for the observed recombinant classes indicated that the transferase locus mapped between *str* and *metA* Taken together with the negative result of the cross with Hfr*A*, the data show that the transferase locus of *SL*1032 is closely linked to *xyl* and lies between *str* and the point of origin of Hfr*A* (Fig 2) but do not show on which side of *xyl* it is Two further glucosyl transferase mutants, *SL*1061 and *SL*1062, and the two galactosyl transferase mutants, *SL*1033 and *SL*1060, were similarly crossed to Hfr*B*2 In all four crosses 89 per cent or more of recombinants selected for possession of the *xyl*$^+$ and *metA*$^+$ loci of the donor had also its transferase-positive character, as indicated by their phage resistance pattern This suggests that in these four mutants also the site of mutation is close to *xyl* Several *LT*2 rough mutants inferred to be able to make O-specific material but unable to attach it to lipopolysaccharide core (because this material was absent in lipopolysaccharide but accumulated in a non-sedimentable fraction) were mapped in the *str-ile-metA* region by Subbaiah and Stocker[6] and were named *rouA* mutants Probably the genes affected in their *rouA* mutants and the glucosyl and galactosyl transferase genes now reported all form part of a cluster of genes concerned with the synthesis of the lipopolysaccharide core Because there are several such genes, and to accord with the principles of the suggested uniform nomenclature for bacterial genetics[18], we now propose to call mutants with defects in such functions *rfa*, instead of *rouA*, and we assign the symbol *rfaG* to the gene for the transferase which adds the proximal glucose unit (glucose No 1) to lipopolysaccharide, and the symbol *rfaH* to the gene for the transferase which adds a galactose unit (galactose No 1) to the 3 position of glucose No 1 of lipopolysaccharide

Biochemical Characterization of Mutants of *Salmonella typhimurium* lacking Glucosyl or Galactosyl Lipopolysaccharide Transferases

Previous work[1–5] on the mechanism of biosynthesis of the somatic (0) lipopolysaccharide of *Salmonella typhimurium* has identified four enzymes involved in synthesis of the core region of the polysaccharide*

$$\text{UDP-Glucose} + \text{Glu-deficient LPS} \xrightarrow{\text{glucosyl transferase I}} \text{Glu-LPS} \qquad (1)$$

$$\text{UDP-Galactose} + \text{Glu-LPS} \xrightarrow{\text{Galactosyl transferase I}} \alpha\text{-Gal-1,3-Glu-LPS} \qquad (2)$$

$$\text{UDP-Glucose} + \alpha\text{-Gal-1,3-Glu-LPS} \xrightarrow{\text{Glucosyl transferase II}} \text{Glu-}\alpha\text{-Gal-1,3-Glu-LPS} \qquad (3)$$

$$\text{UDP-}N\text{-Acetylglucosamine} + \text{Glu-}\alpha\text{-Gal-1,3-Glu-LPS} \xrightarrow{N\text{-Acetylglucosaminyl transferase}} \text{GlcNAc-Glu-}\alpha\text{-Gal-1,3-Glu-LPS} \qquad (4)$$

The tetrasaccharide sequence so formed makes up the distal portion of the core region (Fig 1, preceding communication) and is linked through the proximal glucosyl unit to the heptose-containing polysaccharide backbone It should be noted that the complete core structure contains a second galactosyl residue linked as an α-1,6 branch to the proximal glucose unit[6] The enzyme (galactosyl transferase II) responsible for addition of this galactose to the chain has not yet been demonstrated in a cell-free system A lipopolysaccharide (glu-deficient LPS) which is able to act as acceptor of glucosyl residues in reaction (1) was obtained from a mutant strain lacking phosphoglucose isomerase (*SL*797) (ref 7) This organism is deficient in biosynthesis of UDP-glucose and is therefore unable to carry out reaction (1) *in vivo* As a result, an incomplete lipopolysaccharide is formed, the polysaccharide components of which contain only the constituents of the backbone (heptose, KDO, ethanolamine and phosphate) Similarly, mutants which lack UDP-galactose-4-epimerase and fail to synthesize UDP-galactose are unable to carry out reaction (2) and subsequent steps Such organisms produce an incomplete lipopolysaccharide which terminates at the first glucosyl residue of the core (compare Fig 1, preceding communication), and serves as acceptor of galactosyl residues in the isolated galactosyl transferase I system[1–3]

In mutants deficient in biosynthesis of a nucleotide sugar, the defect in lipopolysaccharide synthesis is a secondary phenomenon resulting from a lack of the required substrate, rather than from absence of the glycosyl transferase enzyme The present report is concerned with biochemical characterization of two classes of mutants lacking glucosyl transferase I and galactosyl transferase I, respectively These mutants were isolated by Wilkinson and Stocker (see previous communication) as galactose-positive strains sensitive to phage *C*21. Of ten isolates examined, eight have been found to lack glucosyl transferase I activity (reaction (1)), while two contain normal concentrations of this enzyme but are deficient in galactosyl transferase I (reaction (2))

The mutants could be divided into two classes on the basis of lipopolysaccharide composition Lipopolysaccharide was isolated from each of the mutants by extraction with aqueous phenol, and purified by precipitation with magnesium chloride[1] The sugar composition was examined qualitatively by acid hydrolysis and paper chromatography In eight strains (*SL*1004, *SL*1005, *SL*1006, *SL*1032, *SL*1059, *SL*1061, *SL*1062 and *SL*1063) heptose, KDO and glucosamine (from lipid *A*) were the only sugars observed Neither glucose nor galactose could be detected, and O-specific sugars (mannose, rhamnose and abequose) were also absent These results were confirmed by quantitative analysis of lipid-free polysaccharide preparations obtained from three of these strains (Table 1) The polysaccharides contained normal amounts of heptose and KDO, but no detectable glucose, galactose or glucosamine The composition of these lipopolysaccharides was very similar to that of the mutant unable to synthesize UDP-glucose[7] In contrast, both glucose and galactose were present in the polysaccharides isolated from *SL*1033 and *SL*1060 (Table 1) however, the molar ratio of these sugars relative to heptose was approximately 50 per cent of that observed in the polysaccharide of *TV*119, an *rfb* (=*rouB*) mutant which forms the complete core structure

---

* LPS, Lipopolysaccharide, glu, glucose, gal, galactose, GlcNAc, *N*-acetylglucosamine, KDO, 3 deoxy-D-manno octulosonic acid

Table 1 CARBOHYDRATE COMPOSITION OF THE POLYSACCHARIDES OF GAL$^+$ C21^s MUTANTS

Mutant strain	Heptose	KDO	Molar ratio Glucose	Galactose	Glucosamine
*SL*1004	1 0	0 42	0 04	0 02	0 02
*SL*1005	1 0	0 51	0 02	0 02	0 02
*SL*1032	1 0	0 56	0 02	0 02	0 02
*SL*1033	1 0	0 54	0 56	0 59	0 05
*SL*1060	1 0	0 44	0 50	0 66	0 08
rfb (*TV*119)	1 0	0 53	1 12	0 89	0 47

Lipid-free polysaccharides were prepared by mild acid hydrolysis of lipopolysaccharide[15] KDO was determined by the semicarbazide method[16], and heptose by a previously described modification[15] of the cysteine-sulphuric acid reaction[17] Analyses for glucose, galactose and glucosamine were performed after acid hydrolysis of the polysaccharide (1 *N* hydrochloric acid, 3 h, 100° C) Glucose and galactose were determined with glucose and galactose oxidase, and hexosamine by the method of Reissig *et al* [18]

Table 2 ACCEPTOR ACTIVITIES OF MUTANT LIPOPOLYSACCHARIDES IN THE SOLUBLE GLYCOSYL TRANSFERASE SYSTEMS

Source of lipopolysaccharides	Acceptor activity (mμmoles of sugar incorporated) Glucosyl transferase I	Galactosyl transferase I
*SL*1004	1 00	0 08
*SL*1005	1 62	0 04
*SL*1006	1 19	0 05
*SL*1032	1 36	0 01
*SL*1059	1 24	0 17
*SL*1061	0 96	0 05
*SL*1062	0 89	0 12
*SL*1063	0 74	0 01
*SL*1033	0 09	1 82
*SL*1060	0 21	2 40
EI-1 (*pgi*$^-$, *gal-epi*$^-$)	0 72–1 54	0 07–0 19
G-30 (*gal-epi*$^-$)	0 06–0 18	1 54–2 17

Purified lipopolysaccharides were employed as acceptors in the standard assay system of Rothfield and Horecker[6] Comparable amounts of acceptor (8–11 mμmoles, as heptose) were employed in each case Standard acceptors for glucose (strain *EI*-1) and galactose (strain *G*-30) were included in each experiment, and the figures given show the range of values observed with these lipopolysaccharides *EI*-1 is a double mutant lacking both phosphoglucose isomerase and UDP-galactose-4-epimerase[4,8] The enzyme fraction consisted of the 105 000*g* supernatant fraction obtained from strain *EI*-1, this preparation contains both glucosyl and galactosyl transferase activity Incubations were continued for 60 min in order to give maximal levels of incorporation of both sugars

Table 3 SOLUBLE TRANSFERASE ACTIVITIES

The 105,000*g* supernatant fraction was prepared from the indicated strains by the method of Rothfield and Horecker[8] Strain *EI*-1 is a mutant of *S typhimurium* lacking both phosphoglucose isomerase and UDP-galactose-4-epimerase, and has been used in this laboratory as a standard source of both soluble glycosyl transferase enzymes The enzyme fractions were assayed as described by Rothfield and Horecker[8] Glucose-deficient lipopolysaccharide employed as acceptor in the glucosyl transferase assay was isolated from *EI*-1 The galactose-deficient lipopolysaccharide of the UDP-galactose-4-epimerase mutant, *G*-30, was employed as acceptor in the galactosyl transferase assay

The ability of the purified mutant lipopolysaccharides to act as *in vitro* acceptors of glucosyl and galactosyl residues in reactions (1) and (2) was tested using the soluble glucosyl transferase I and galactosyl transferase I systems described before[8–10] The results are summarized in Table 2 As expected, those lipopolysaccharides which lacked glucose were active as acceptors in the glucosyl transferase I reaction, and their activity was equal to that of the chemically similar lipopolysaccharide produced by a phosphoglucose isomeraseless mutant which is unable to synthesize UDP-glucose The lipopolysaccharides of this group did not accept galactose, presumably because they lacked the glucosyl residues which are necessary for attachment of galactose The lipopolysaccharides of *SL*1033 and *SL*1060 showed the opposite pattern of acceptor activity. In spite of the fact that these lipopolysaccharides already contained 50 per cent of the normal amount of galactose, they were highly active as acceptors in the galactosyl transferase I system Both the rate of galactose incorporation and the total amount incorporated were indistinguishable from that obtained with the lipopolysaccharide of a UDP-galactose-4-epimeraseless mutant (*G*-30), which is completely devoid of galactose The lipopolysaccharides of *rfa* (=*rouA*) and *rfb* mutants, which contain the normal complement of galactose, did not accept galactose in the soluble transferase system The composition of the lipopolysaccharides of *SL*1033 and *SL*1060, together with their acceptor activities in the galactosyl transferase reaction, suggested that those strains might lack galactosyl transferase I (which catalyses addition of galactose to the 3-position of glucose), but retain a second, independent activity specifically transferring galactose to the 6-position of glucose (galactosyl transferase II)

Determination of soluble transferase activities in extracts of the mutant strains confirmed that the two classes were deficient in glucosyl transferase I and galactosyl transferase I, respectively (Table 3) No significant glucosyl transferase activity was detected in the 105,000*g* supernatant fractions obtained from the eight mutants the lipopolysaccharide of which lacked glucose Essentially normal concentrations of soluble galactosyl transferase activity were found in these organisms By contrast, the glucosyl transferase I activities of *SL*1033 and *SL*1060 were within the normal range, but the soluble galactosyl transferase activity of these strains was only 10–15 per cent of the normal level The available evidence indicates that the galactosyl transferase activity observed in cell-free systems results in addition of galactose predominantly if not exclusively, to the 3-position of glucose, and it appears to be this enzyme activity which is lacking in *SL*1033 and *SL*1060 It is not yet clear whether the low residual levels of galactosyl transferase activity observed in extracts of these strains represent the α-6-galactosyl transferase (transferase II) or reflect leakiness in the transferase I defects There is evidence that *in vivo* the block in lipopolysaccharide biosynthesis is not absolute, which suggests that in both strains the defects are somewhat leaky

Mutants of *SL*1033 and *SL*1060 lacking galactosyl transferase I would be expected to produce an incomplete polysaccharide of the type

$$\begin{array}{l}\text{glu—[hep, KDO, PO}_4\text{, ethanolamine]}\\ 1{,}6\ |\\ \alpha\text{-gal}\end{array}$$

Evidence for this structure was obtained by characterization of the oligosaccharide products of partial acid hydrolysis of the polysaccharides Lipid-free polysaccharide fractions derived from *SL*1033 and *SL*1060 were hydrolysed as previously described[11] with 60 per cent formic acid (45 min at 100° C), and the products were separated by preparative paper chromatography (Whatman No 3 *MM* paper, descending chromatography in ethyl acetate acetic acid H_2O (3 1 3) for 96 h) As a control, parallel experiments were also carried out with the polysaccharide of an *rfa* mutant (*TV*161), which contains both galactosyl residues The hydrolysates of the *SL*1033 and *SL*1060 polysaccharides showed a single major oligosaccharide product with an R_F identical to that of melibiose (α-galactosyl-1,6-glucose) This material was also present as a major component in the hydrolysate from the *rfa* strain The disaccharides from the three polysaccharides were indistinguishable from each other, and from melibiose, in chromatography in four solvent systems, and in borate electrophoresis The reduced disaccharides also had the same electrophoretic mobility as melibitol in sodium molybdate buffer, *p*H 5 Analytical data confirmed the identification as α-galactosyl-1 6-glucose (*a*) each oligosaccharide contained equimolar amounts of glucose and galactose (as determined by enzyme assay with glucose and galactose oxidase after acid hydrolysis), (*b*) reduction of the oligosaccharides with $NaBH_4$ led to destruction of more than 90 per cent of the glucose, with quantitative recovery of galactose, (*c*) treatment with coffee bean α-galactosidase resulted in quantitative hydrolysis of the oligosaccharide with liberation of corresponding amounts of free glucose and galactose, (*d*) periodate oxidation of the reduced disaccharides gave 0 93 to 1 17 moles of formaldehyde/mole of disaccharide

No fraction corresponding to the other possible galactose disaccharide, α-galactosyl-1,3-glucose, was detected in the partial acid hydrolysates of any of these strains This galactosyl linkage has previously been found to be extremely acid-labile[3] The hydrolysate of the *rfa* polysaccharide, however, contained a minor component in the trisaccharide area which was tentatively identified as the branched trisaccharide

α-gal-1,3-glu
1,6 |
α-gal

This component was entirely absent from the hydrolysates of *SL*1033 and *SL*1060 Although not conclusive, the results provide some additional support for the hypothesis that the α-galactosyl-1,3-glucose linkage is lacking in these mutants

The glucosyl and galactosyl transferaseless mutants, like *rfa* strains, form incomplete core polysaccharides which presumably lack the sites required for attachment of the O-specific side chains Beckmann and her colleagues[12] have shown that, although the lipopolysaccharides of *rfa* mutants are devoid of O-antigen, these strains produce a separate polysaccharide chemically and immunologically similar to the O-specific side chains of the lipopolysaccharide (O-specific hapten) The hapten was not found in *rfb* mutants, in which the lesion directly affects synthesis of the O-antigen chain Examination of the mutants lacking glucosyl or galactosyl transferase for the presence of O-specific hapten is summarized in Table 4 The hapten-containing fraction was obtained from the aqueous phenol extract after removal of lipopolysaccharide by magnesium chloride precipitation, as described in the legend The presence of the O-specific sugars (mannose, rhamnose and abequose) in this fraction was taken as the criterion for the presence of hapten As expected, no hapten was detected in transferase-negative strains derived from an *rfb* parent. Large amounts of this material, however, were found in *SL*1032, a glucosyl-transferase-negative strain derived directly from the wild type The lipopolysaccharide of *SL*1032 was entirely free of O-specific sugars The two galactosyl transferase mutants, *SL*1033 and *SL*1060, and three of the strains lacking glucosyl transferase are double mutants which also lack phosphomannose isomerase Except when provided with an external supply of mannose, these organisms are unable to synthesize GDP-mannose, a required precursor of O-antigen mannose[11] When the five strains were grown on mannose-supplemented medium, O-specific hapten was recovered in large amounts Chromatographic analysis of the lipopolysaccharide fractions obtained from mannose-grown cells also showed in each case the presence of small amounts of the O-specific sugars This suggested that the transferase defects in these strains might be somewhat leaky In order to obtain more quantitative information, strains *SL*1060 (galactosyl-transferase-deficient) and *SL*1061 and *SL* 1062 (glucosyl-transferase-deficient) were grown in the presence of ^{14}C-mannose, and the relative amounts of radioactivity in lipopolysaccharide and the haptenic fraction determined After phenol extraction of the cell envelopes, the total polymer fraction (that is, lipopolysaccharide plus hapten) was isolated by gel filtration on 'Sephadex *G*-25', and hapten and lipopolysaccharide were separated by filtration on 'Sephadex *G*-200' Lipopolysaccharide is excluded from the gel, while the haptenic material is recovered in the partially included fraction Ultracentrifugation and chromatography on DEAE cellulose confirmed identification of the two fractions The amount of ^{14}C-mannose recovered in the lipopolysaccharide fraction, expressed as percentage of total radioactivity incorporated into polymeric form, was 22 per cent in *SL*1060, 19 per cent in *SL*1061 and 12 per cent in *SL*1062 In parallel experiments carried out with a phosphomannose isomeraseless mutant (M_2) (ref 11) with normal core transferase function, more than 98 per cent of the total ^{14}C-mannose incorporated into polymeric form was recovered as lipopolysaccharide, and only trace amounts in hapten The total incorporation of ^{14}C-mannose into O-antigen, however, was seven to ten times greater in M_2 than in the mutants deficient in glucosyl or galactosyl transferase Thus, the lipopolysaccharide of the transferase-deficient strains actually contained only 1–2 per cent of the normal amount of mannose

Table 4 PRESENCE OF HAPTENIC O-ANTIGEN

	Plus mannose	+

Cell envelope fractions prepared from 10 g wet weight of cells were extracted with 45 per cent phenol at 70° C (ref 1) Lipopolysaccharide was precipitated from the aqueous phase with magnesium chloride (ref 1) The supernatant fractions were concentrated and the bulk of the RNA was removed by precipitation at *p*H 3 0 The supernatant material was deionized and low molecular weight material was removed by passage through 'Sephadex *G*-25' Samples of the excluded fractions were hydrolysed in 0 1 N hydrochloric acid for 15 min at 100° C for detection of abequose, and in 1 N hydrochloric acid for 3 h at 100° C for detection of other sugars The sugar composition was determined by paper chromatography in *n*-butanol pyridine water (6 4 3)

The results indicate that formation of the O-specific hapten is a general property of mutants which are blocked in biosynthesis of the core region of the lipopolysaccharide The incomplete lipopolysaccharides made by such mutants therefore presumably lack a structure required for attachment of the O-specific chains Studies on the mechanism of biosynthesis of O-antigen (refs 13 and 14 and unpublished work of Osborn and Kent) have provided some support for the hypothesis that the hapten represents a precursor of the O-specific side chains of lipopolysaccharide, but have not entirely excluded the possibility that this material is formed as a side product only in conditions in which the normal biosynthetic sequence is disturbed

PHYSIOLOGY

Membrane Surface Specialization of Blood Platelet and Megakaryocyte

Recent evidence has indicated the importance of the surface of blood platelets in initiating the chain reaction in relation to platelet aggregation, and the formation of haemostatic plugs and thrombi[1-3] During an investigation of the coating of the platelet surface, we noticed an elaborate surface structure which differs from that of other blood cells (unpublished results)

Platelet-rich plasma and platelet concentrates were prepared as follows 450 ml and 10 ml of whole blood were drawn from normal human and rat, respectively, with sodium citrate or heparin as anticoagulant The blood was centrifuged at 1,300 and 1,800 r p m for 15 min at room temperature to obtain platelet-rich plasma and platelet concentrate, respectively Samples (3 ml) of each, in a conical centrifuge tube, were fixed with osmium[4] Another 3 ml of each was fixed with ruthenium red, as suggested by Luft[5] and Kelly[6] The final sediment was dehydrated in a series of graded concentrations of acetone and embedded in 'Epon' Thin sections were cut on a Porter-Blum ultramicrotome and examined with a Hitachi electron microscope

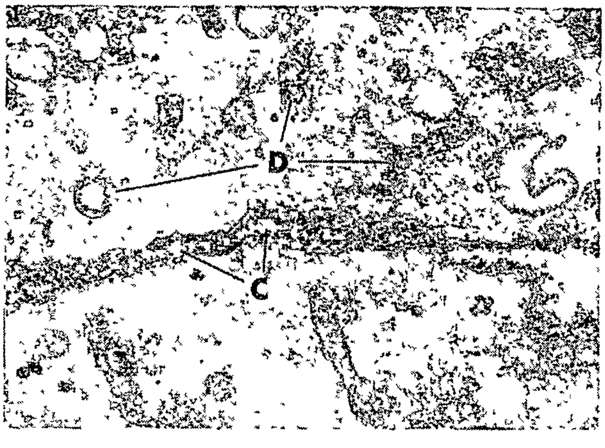

Fig 1 Two blood platelet surfaces in contact show dense extraneous coat across the midline of the micrograph and identical pattern in demarcation tubules (*D*) *C*, Space surrounded by surface patches Ruthenium red preparation stained with uranyl and lead (×*c* 65,800)

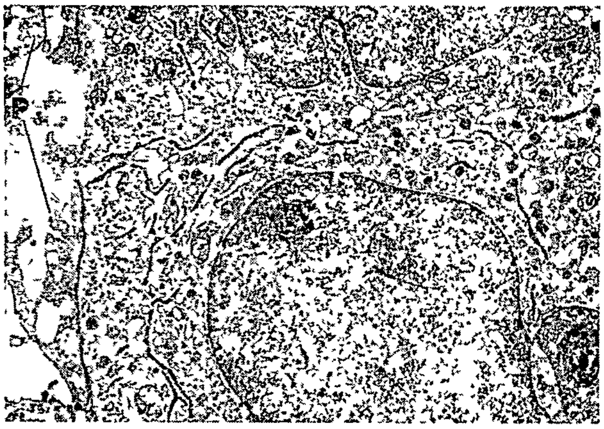

Fig 2 A portion of megakaryocyte shows selective staining of demarcation system The left edge of the picture shows detaching platelets (*P*) Ruthenium red preparation, otherwise unstained (×*c* 3,950)

Bone marrow from several rats (10 days and 1 yr old) was prepared for electron microscopy as follows one limb was injected through the femoral artery with the combination of glutaraldehyde fixative in cacodylate buffer containing ruthenium red The other limb was injected similarly with either 6 per cent glutaraldehyde in cacodylate buffer[7] only, or buffered osmium tetroxide The marrows were then processed identically

In contrast to the platelets and megakaryocytes, none of the other blood cells showed obvious extraneous coating in ruthenium red preparations The platelets showed distinct dense patches on the outer dense layer of the unit membrane as shown in Fig 1 The circulating blood platelet surface was studded with ruthenium red stained material, which varied in size between 50 and 300 Å (average 100 Å) and was irregularly globular There was also noticeable variation in staining, suggesting heterogeneity in composition The interior cytoplasm of the platelets contained many tubular and vesicular profiles which were identical in appearance to the plasma membrane (Fig 1*D*) but inverted or inside-out No other structures showed staining comparable to the extraneous coating

The bone marrow showed exclusive and dramatic staining of megakaryocyte (Fig 2) in the region of the intracellular demarcation system and in the intercellular adherent material at the interface between the megakaryocytes and other bone marrow cells The megakaryocytes (Fig 2) showed almost identical ruthenium red stained material at the surface of developing platelets The cytoplasm of megakaryocytes showed numerous vesicles and tubules which again revealed intense staining with ruthenium red These vesicles and tubules are identical in structure with the membrane of the circulating blood platelets, and coincide precisely with the demarcation system which occurs in the development, maturation and separation of platelets[8]

Furthermore, the midzone of the exoplasm of Heidenhain showed numerous myelin figures—reported earlier as lipoid granules (lecithin)[9]—intermingled with the demarcation tubules The myelin figures were associated with a microglobular structure, particularly toward its surface lamellae, suggesting micro-emulsification of myelin figures

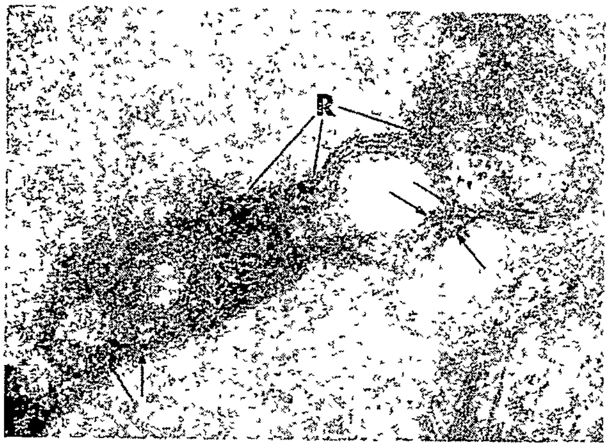

Fig 3 Part of the demarcation tubules in Fig 2 shows electron-dense ruthenium red stained material (*R*) surrounding the myelin figures Arrows indicate developing microglobular structure of phospholipid micromicelles Ruthenium red preparation, otherwise unstained (×c 131,600)

in relation to phospholipid micelles, measuring 10–30 Å, and apparently embedded in mucopolysaccharide present within the demarcation tubules (Fig 3) This specialized type of chemical assembly suggests a possible site of localization of coagulation factors[10,11]

Ruthenium red reacts strongly with chondroitin sulphate and so our finding supports the existence of a mucopolysaccharide, probably a chondroitin sulphate, in the extraneous coat, this has been reported previously from chemical analysis although no precise localization was found[12,13] This structural elaboration suggests that blood platelets have a specialized function in aggregation and haemostasis, they would rapidly form an agglutinated platelet mass when altered by various factors, such as *p*H, ionic strength, size and shape of interactants, and so on[14–16], besides foreign surfaces, especially collagen fibrils[17–19] This seems to support the suggestion of a "masking" and "unmasking" mechanism of functionally active phospholipid micelles[20–22]

Furthermore, the patchy layer of acid mucopolysaccharide on the surface seems to be very interesting when compared with the red blood cell surface Morgan has suggested that the stability of the erythrocyte plasma membrane is probably related to either an enzyme mechanism or mucopolysaccharide patches at the surface[23] We have not so far encountered such specialization of the surface of the erythrocyte in our preparations

The structural integrity of specifically combined phospholipid micelles, mucopolysaccharide and serum proteins (Fig 1*C*) suggests that the triggering of normal and abnormal adhesiveness depends on the "plasmatic milieu" produced

Simultaneously Recorded Oscillations in Membrane Potential and Isometric Contractile Force from Cardiac Muscle

IN 1943, Bozler[1,2] reported unusual sinusoidal oscillations in membrane potential and contractile tension which occurred immediately after relaxation of a normally triggered contraction in turtle heart muscles bathed in calcium solutions of high concentrations Reiter[3–5] observed similar contractile oscillations (which he called "aftercontractions") in mammalian myocardium in a variety of conditions that enhance contractility Contractile oscillations have been shown to be unaccompanied by propagated action potentials[4,6] Kaufmann's group, however, detected slow corresponding oscillatory waves in membrane potential similar to those described by Bozler, and they assumed that the contractile oscillations are initiated by electrical oscillations

Oscillatory contractile phenomena in cardiac muscle have now been studied in detail[3–5,7,8], but a similarly detailed analysis of oscillatory electrical phenomena and the relation of electrical oscillations to contractile oscillations has not been made In this communication, we report some preliminary observations for simultaneously recorded electrical and contractile oscillations in guinea-pig left atrial preparations in a variety of conditions The results indicate that there is a direct coupling between electrical and mechanical activity in cardiac muscle in these conditions

The atria were isolated from animals of either sex weighing 470–810 g Each preparation was mounted horizontally in a 'Plexiglas' muscle chamber surrounded by a thermostatically controlled water jacket One end of the preparation was impaled on a strain gauge ('Grass *FT*-03') lever arm The other end was fixed to the terminus of an adjustable rod, the movement of which provided the establishment of the resting length of the muscle All preparations were continuously perfused at a rate of about 3 ml /min with a solution composed of 154 mM sodium chloride, 5 6 mM potassium chloride, 7 1 mM sodium bicarbonate, 11 2 mM dextrose and 5 0 or 10 0 mM calcium chloride as indicated Intracellular membrane potentials were recorded by conventional microelectrode techniques[9] Transduced muscle contractions and membrane potentials were displayed on a 'Tektronix 565' oscilloscope and photographed with a 'Tektronix' oscilloscope camera, or were recorded with a 'Grass' direct writing oscillograph

Each preparation was initially driven at a basal stimulus interval of 1,000 ms at a temperature of 30° C for a period of not less than 60 min. After being stabilized the tissue was perfused with a high concentration calcium solution (10 0 mM) and the temperature of the bath was lowered at a rate of about 1°/min to 20° C or less (minimum of

10° C) Oscillations in membrane potential (electrical oscillations) and isometric contractile tension (mechanical oscillations) were then elicited or "unmasked" by stimulating the preparation with repeated trains of impulses (40 impulses per train) at stimulus intervals of 400, 500, 630, 800 or 1,000 ms, alternated with (*a*) periods of quiescence, or (*b*) periods of stimulation at a constant stimulus interval of 2,000 ms In this communication, oscillations (electrical as well as mechanical) recorded during quiescent periods are termed "post-stimulation oscillations", and oscillations recorded between stimulated contractions are referred to as "inter-stimulation oscillations"

Electrical and mechanical oscillations were observed in a total of fifteen atrial preparations Firm criteria were established for transmembrane recordings considered suitable for analysis of oscillatory electrical phenomena at high sensitivities These criteria were uniform action potential configuration (that is, smooth repolarization phase and constant AP amplitude) during the train of driven beats, and a noise level of less than ± 1 mV All records not meeting these criteria were rejected

Representative examples of electrical and mechanical oscillations recorded from guinea-pig atrium are shown in Fig 1 At all times the recorded mechanical oscillations were found to be identical with those previously described for guinea-pig atria in similar conditions[3,7,8] Furthermore, the electrical oscillations observed in this study were generally comparable with those reported by Kaufmann *et al*[6] In each case the oscillatory wave was smooth and sinusoidal, with the electrical peak generally preceding the mechanical peak In the quiescent period after a series of stimulated contractions (post-stimulation oscillations, Fig 1, *A* and *B*) the electrical and mechanical oscillation peaks were followed by a slow curvilinear recovery toward resting conditions Multiple oscillation peaks generally occurred in each trace The number of these varied between two and seven and appeared to be directly dependent on the amplitude of the first oscillation in the trace Two extra beats (stimulated) are interpolated into the quiescent period in Fig 1*A* Each elicited a small oscillatory electrical and mechanical response but did not alter the overall pattern of the slow recovery phase Oscillations occurring between a series of stimulated beats following a change in driving rate (interstimulation oscillations) are presented in Fig 1*C* The amplitude of both the electrical and mechanical oscillation progressively decreases with oscillation number (that is, between the first and last oscillation of the series) The change in oscillation amplitude as a function of oscillation number has been plotted for another experiment in Fig 2, which also shows concurrent changes in oscillation rise time These data make it evident that changes in electrical oscillatory phenomena closely parallel those in mechanical oscillatory phenomena This relationship holds for quantitative as well as qualitative changes Temperature has been shown to be a very important determinant of mechanical oscillatory activity[7] Fig 3 illustrates the effect of this variable on simultaneously recorded electrical and mechanical oscillations As temperature is decreased the amplitude of both the electrical and mechanical oscillations increases, again in a closely parallel fashion

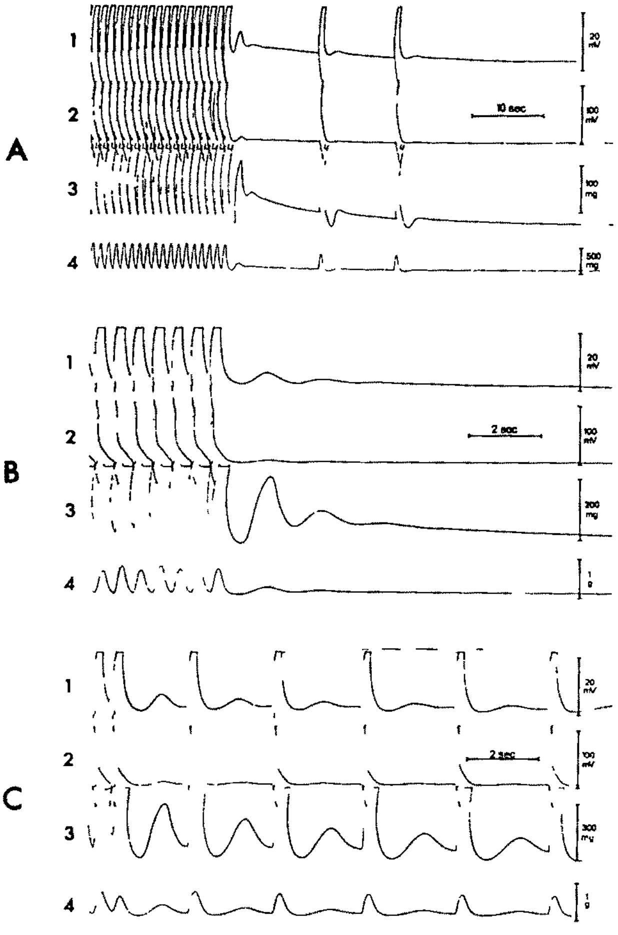

Fig 1 Photograph of oscillations in membrane potential and isometric contractile tension recorded from guinea-pig left atrium with a direct writing oscillograph The temperature was 18° C The calcium concentration of the bath was 10 0 mM *A* and *B* show oscillations occurring during a quiescent period (post-stimulation oscillations) following a train of forty driven contractions at a 630 ms stimulus interval *C* shows oscillations occurring between stimulated contractions (interstimulation oscillations) following a change of stimulus interval of 500–2,000 ms Two extra beats occur during the quiescent period of *A* Numbers on left indicate polygraph channel (1) high sensitivity electrical, (2) low sensitivity electrical, (3) high sensitivity mechanical, (4) low sensitivity mechanical

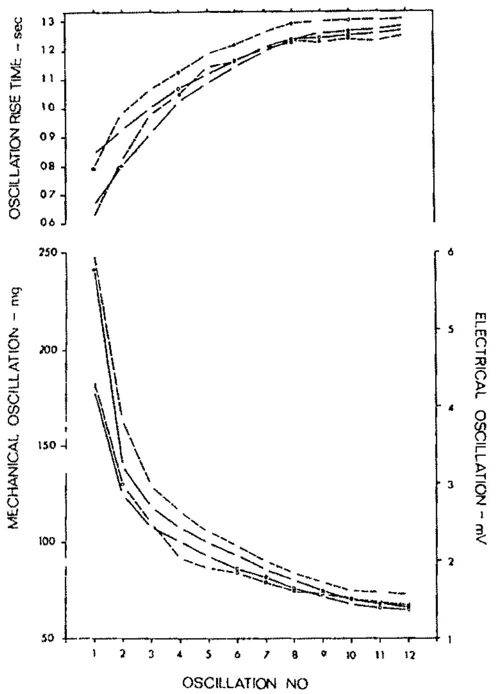

Fig 2 Relation between oscillation amplitude (lower), oscillation rise time (upper), and oscillation number in a series of interstimulation oscillations Oscillation rise time and amplitude measured between origin and peak of oscillation Guinea-pig left atrium was used (——) Mechanical oscillations, (– – – –) electrical oscillations Stimulus interval of preceding train 500 ms (●), and 630 ms (○) The temperature was 20° C The calcium concentration of the bath was 10 0 mM

A primary purpose of this work was to establish an initial correlation between oscillatory electrical changes at the cardiac cell membrane and oscillatory contractile responses within the cell Previous efforts to relate electrical activity with mechanical activity in muscle, both

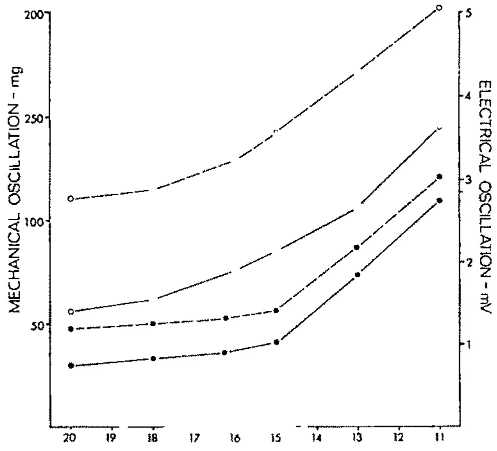

Fig 3 Effect of change in temperature on electrical (– – – –) and mechanical (——) oscillation amplitude Guinea-pig left atrium was used Stimulus interval of preceding train 630 ms (○), and 800 ms (●) The calcium concentration of the bath was 10 0 mM

skeletal and cardiac, have been chiefly concerned with attempting to correlate changes in resting or action potentials with contractile changes, and usually very little correlation has been found (see ref 10) In the present work with guinea-pig atria, we have found good correlation between membrane electrical activity and developed tension in the form of oscillatory electrical and contractile responses

In the interpretation of these results, two important questions immediately arise are the electrical oscillations artefacts arising from the mechanical oscillations and, if not, do the electrical oscillations elicit, and in some way control, the time course of the mechanical oscillations ? That the electrical oscillations are not artefacts is suggested by the smoothness and remarkable repeatability of oscillatory changes in membrane potential This idea is supported by the fact that the electrical and mechanical events can be altered in parallel, with oscillation amplitude inversely related to rise time in the case of the electrical as well as the mechanical oscillations A third, more indirect piece of evidence is suggested by the fact that electrical oscillatory phenomena are not unknown in excitable tissues, in addition to the previously mentioned examples in cardiac muscle[1,2,6], electrical oscillations of various forms have been documented for nerve tissue[11], smooth muscle[12] and skeletal muscle[13] in a variety of conditions At this stage of the investigation no answer can be given as to the mechanisms involved in electrical and mechanical oscillatory phenomena It is clearly evident, however, that there is a close relationship between the two events

Distribution of Ethanol between Plasma and Erythrocytes in Whole Blood

When capillary and venous blood samples were collected simultaneously from volunteers who had taken varying quantities of alcohol by mouth, certain discrepancies were noted in their alcohol content Further investigation revealed that when added to human blood *in vitro* ethanol was distributed unevenly between the plasma and the red cells[1] If a similar uneven distribution could be demonstrated *in vivo* when alcohol was absorbed from the gut, it might help to explain the differences between capillary blood and venous blood It might also help to explain the observed discrepancies in the blood breath ratios and urine blood ratios reported by different authors

Accordingly twenty volunteers were invited to drink varying quantities of alcohol in the form of whisky or gin during a period of up to 1 h A blood sample of approximately 20 ml was then withdrawn from a superficial vein on the forearm Part of the sample was used to derive the alcohol content of whole blood by duplicate analysis using the Nickolls modification[2] of the Cavett method, a second small fraction was used to determine the haematocrit value The remainder of the sample was placed in a glass test tube sealed with a ground-glass stopper and spun at 2,000 r p m for 20 min at room temperature in a Griffin–Christ centrifuge (type *UJ* 3) After centrifuging, enough plasma and packed red cells were removed separately by pipette to allow duplicate analyses Again the alcohol content was determined by the Nickolls modification of the Cavett method By means of the haematocrit value and a correction factor for trapped plasma[3] the alcohol content of the whole blood sample was calculated from the plasma and erythrocyte contents for comparison with the measured value

Table 1 ALCOHOL CONTENT IN PLASMA, ERYTHROCYTE AND WHOLE BLOOD SAMPLES FROM TWENTY VOLUNTEERS, TOGETHER WITH THE RATIOS OF DISTRIBUTION

		Alcohol content (mg/100 ml)				Ratios	
Subject (1)	Haematocrit (2)	Whole blood (3)	Plasma (4)	Red blood cells (5)	Calculated whole blood (6)	Plasma red blood cells (7)	Plasma whole blood (8)
1	39	114	127	93	114	1 37/1	1 11/1
2	45	148	181	96	143	1 89/1	1 22/1
3	39	58	68	46	59	1 48/1	1 17/1
4	46	87	101	74	89	1 36/1	1 16/1
5	42	70	83	52	70	1 60/1	1 19/1
6	42	64	78	54	68	1 44/1	1 22/1
7	37	44	50	33	44	1 52/1	1 14/1
8	47	41	49	31	41	1 58/1	1 20/1
9	45	41	49	35	43	1 40/1	1 20/1
10	41	48	58	39	50	1 49/1	1 21/1
11	44	37	46	29	38	1 59/1	1 24/1
12	29	43	48	38	45	1 26/1	1 12/1
13	43	60	69	47	59	1 47/1	1 15/1
14	46	40	49	31	41	1 58/1	1 23/1
15	40	21	24	16	21	1 50/1	1 14/1
16	48	167	189	134	163	1 41/1	1 13/1
17	45	68	75	48	63	1 56/1	1 10/1
18	45	66	89	45	69	1 98/1	1 35/1
19	50	52	62	35	49	1 77/1	1 19/1
20	46	54	62	38	51	1 63/1	1 15/1

The values obtained are set out in Table 1 from which it is obvious that the alcohol content of plasma was consistently higher than that of the erythrocytes by a mean factor of 1 54 (*S D* 0 176) with a range from 1 26 to 1 98 Similarly the alcohol content of the plasma was consistently higher than that of the corresponding whole blood In this instance, the plasma : whole blood ratio was 1 18 1 (*S D* 0 057) with a range of 1 10 to 1 35 No significant difference between the measured values and the calculated values for the alcohol content of whole blood was observed ($P > 0\ 9$)

Expressed in another way, it can be shown that the distribution of alcohol between the plasma and red blood cells of a given blood sample has a ratio of about 2 1 (mean of twenty samples 2 07 1, *S D* 0 365, range 1 53 to 3 09)

The idea that there is a difference in the distribution of alcohol between the plasma and the erythrocyte components of whole blood is not new In 1923, Miles[4] demonstrated in ten volunteers that the alcohol concentration in the plasma was between 20 per cent and 25 per cent higher than that in whole blood On the basis of these measurements, he calculated that the alcohol content of the plasma component was about twice that of the red cell component of a given blood sample Our results, obtained by direct measurement, are in broad agreement with the calculated values given by Miles

The difference in alcohol content between plasma and red blood cells can be attributed to the uneven distribution of water between plasma and cells, as suggested by the work of Polonovski, Lindenberg and Rabussier[5] on dogs and later confirmed by that of Gruner[6] on man Gruner showed that alcohol and water had the same uneven distribution between plasma and cells His ratio of 1 15 1 is slightly lower than our figure of 1 18 1, but this can probably be explained by the small size of his series of four subjects

The significance of this observation is that it invalidates the use of such accepted standards as the urine blood ratio and the blood breath ratio for the determination of blood alcohol levels When the distribution of alcohol has reached equilibrium in the body, the tissue levels, including those of the lung and kidney, reflect the concentration in the plasma In particular, the tension, and therefore the amount, of alcohol in the alveolar air is in equilibrium with the tension in the plasma which in turn is directly related to the plasma concentration But because the plasma concentration is substantially higher than the red cell concentration the whole blood concentration must vary inversely with the haematocrit for any given plasma concentration and therefore for any given breath concentration Thus it follows that the blood breath ratio and similarly the urine blood ratio cannot be constant even in one individual but must always be dependent on the haematocrit once equilibrium has been achieved

This problem would be eliminated if plasma breath and urine plasma ratios were used

Variations in Embryospecific Globulins of Human Blood Sera in Foetuses and the Newborn

The use of immunochemical methods for studying the composition of foetal human blood serum proteins led to the discovery of, in addition to the known alpha foetoprotein[1-8], other embryospecific globulins with electrophoretic mobility of beta$_1$ (refs 5, 6, 9) and beta$_2$ globulins[9] Alpha foetoprotein is a relatively constant component of foetal blood serum Embryospecific beta$_1$ globulin was discovered in about 75 per cent[9,10] and embryospecific beta$_2$ globulin in 50 per cent of the cases[9]

In 1965 (ref 9), variations of human blood sera were classified with respect to three embryospecific globulins It was interesting to find at what stage of embryogenesis it is possible to discover group variations of foetal sera and whether these variations remain until the end of intrauterine development

Immunochemical investigations of group variations in embryospecific globulins have been carried out on the sera of 6–10 week embryos (medical interruption of pregnancy), 11–30 week foetuses (spontaneous interruption) and 40 week newborns Two hundred and sixty samples of foetal blood sera from one hundred embryos, sixty foetuses and one hundred newborns were studied

Antisera against embryospecific globulins were prepared by repeated reimmunization[6] of rabbits with pooled foetal serum The serum used as the antigen was obtained from 10–30 week foetuses Rabbit antisera against foetal serum were adsorbed by a surplus of pooled human serum obtained from healthy donor adults Detailed descriptions and identification of embryospecific alpha globulin (ESA$_1$ globulin), beta$_1$ globulin (ESB$_1$ globulin), and beta$_2$ globulin (ESB$_2$ globulin) have been given before[9,11]

Foetal sera were tested in identical conditions, by the Ouchterlony method[12] modified by Khramkova and Abelev[13] This modification permits a comparison of an antigen with the antigen of a standard test system, and can reveal an antigen even if it is in a "below threshold" concentration Some selected fractions of globulins of pooled human foetal serum, prepared by electrophoresis on agar gel, were used as the antigens of test systems for determining components of each embryospecific antigen

Each of the embryospecific globulins is found equally often in the sera of embryos, foetuses and newborns[14], the analyses (Tables 1 and 2) did not register the stage of pregnancy ESA$_1$ globulin, the alpha foetoprotein of Bergstrand and Czar[1], is a more constant antigen component in the foetal sera than ESB$_1$ globulin and ESB$_2$ globulin (Table 1) The embryospecific globulins, migrating in the region of beta globulins, may be distinguished not only by electrophoretic mobility (Fig 1), but by their relation to the Schiff reaction It was shown[11] that ESB$_1$ globulin is a typical glycoprotein

The characteristics of foetal sera with respect to three embryospecific globulins are given in Table 2 Sera of group 1, containing all the known embryospecific globulins, were observed more frequently than any other groups The sera of group 2, in which there is a characteristic lack of ESB$_2$ globulin, were found only half as often as sera of group 1 Quantitative relationships between groups 3 and 4 are similar The sera in which there is ESB$_1$ globulin but not ESA$_1$ globulin (groups 5 and 6) were observed in about 2 per cent of the cases Sera from which all the known embryospecific globulins are absent or which contain only ESB$_2$ globulin are found very seldom

Immunochemical investigations of three embryospecific globulins made it possible to subdivide foetal sera into at least eight groups If variations of foetal sera are discovered at an early stage of human embryogenesis and remain up to the end of the period of intrauterine life, genetic control of the synthesis of each embryospecific globulin may be considered

Table 1 EMBRYOSPECIFIC GLOBULINS IN FOETAL HUMAN SERA

Embryospecific antigen components	Total amount of foetal sera in analyses	Positive result	
		Number	Per cent
ESA$_1$ globulin	260	248	95 4
ESB$_1$ globulin	260	194	74 6
ESB$_2$ globulin	260	150	58 4

Table 2 CHARACTERISTICS OF HUMAN FOETAL SERA WITH RESPECT TO THREE EMBRYOSPECIFIC GLOBULINS

Group number	Globulins* present	Number of sera observed with group characteristics	Per cent
1	1–2–3	121	46 4
2	1–2–0	63	24 2
3	1–0–0	44	16 7
4	1–0–3	19	8 1
5	0–2–3	5	1 9
6	0–2–0	5	1 9
7	0–0–3	1	0 4
8	0–0–0	1	0 4

*1—ESA$_1$ globulin, 2—ESB$_1$ globulin, 3—ESB$_2$ globulin

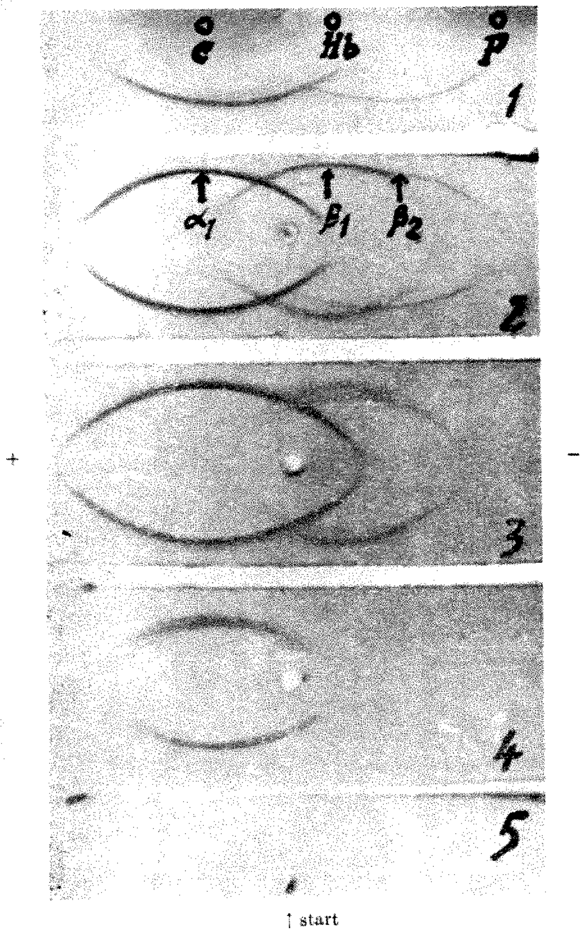

Fig. 1. Immunoelectrophoresis of foetal human sera. Precipitation lines obtained by development with adsorbed antiserum against human foetal serum proteins. Group variations of the embryospecific globulins (Table 2): 1, (1–0–3); 2 and 3, (1–2–3); 4, (1–0–0); 5, adult human serum. The zone of migration: c, colour T-1824; Hb, haemoglobin; p, pyronine.

It will be interesting to find out if antibodies are produced in women during pregnancy where mother and foetus belong to different groups. In such cases some embryospecific globulins would have become heterogenic antigens for the mother. Analogous views relating to stadiospecific antigens can be found in the early literature[15].

In vivo Detection of Circulating Gas Emboli associated with Decompression Sickness using the Doppler Flowmeter

THE ultrasonic Doppler flowmeter[1] has been used to measure blood flow in several animal species[2,3] and man[4,5] by monitoring the frequency shift produced in the scattering of ultrasonic waves by moving blood cells. The extreme sensitivity of this instrument to air bubbles in the circulating fluid is a familiar nuisance encountered during *in vitro* testing and calibration procedures. We have exploited this characteristic for the *in vivo* detection of circulating gas emboli in an animal decompressed rapidly from a hyperbaric environment.

The transducer used in this experiment consists of two piezoelectric crystals mounted opposite each other in a rigid cuff which encircles the vessel. One crystal is electrically excited at a fixed frequency, producing ultrasonic waves which propagate into the vessel at an angle relative to the vessel axis. Waves backscattered from the moving cells cause sympathetic vibrations of the second crystal, producing an electrical signal of a slightly different frequency. The two crystal signals are combined to form an amplitude modulated signal which is then demodulated, producing an audio frequency signal the amplitude of which is a function of the amount of backscattered energy and the frequency of which is directly proportional to flow velocity.

Because of the disparate acoustic properties of plasma and air, the interface between plasma and a gas embolus is a highly efficient scattering surface. A circulating gas embolus thus produces an artefact on the flow signal which may have an amplitude many times greater than the flow background. Such an artefact can be detected by ear even when electronic discrimination is difficult, having a characteristic sound best described as a "chirp".

Because of interest in the miniature swine as a physiological analogue to man, this species was selected for hyperbaric investigations which include evaluation of the Doppler flowmeter as a detector of circulating gas emboli. A thoracotomy was performed on a 60 kg male Hanford miniature swine[6] and the Doppler flow transducer was placed on the caudal vena cava about 8 cm cranial to the diaphragm. After a 3 week recovery period the animal was fitted with a harness assembly on which was fastened the crystal exciter, crystal receiver/demodulator and telemetry transmitter circuits[7]. The blood flow audio signal was telemetered from within the hyperbaric chamber to a receiver outside, thus permitting the animal to move about without danger of lead entanglement.

Using an atmosphere of air the chamber pressure was varied according to a schedule (Fig. 1) consisting of compression to 5·3 atm. gauge (equivalent to about 53 m of sea water), maintenance at that level for approximately 1 h, rapid (6 min) decompression to zero atmospheres gauge, recompression to the original level, and stepwise decompression according to a therapeutic schedule[8] which was admittedly inadequate considering the observed signs of decompression sickness. Flow audio was recorded on magnetic tape throughout the experiment.

The first embolic event, defined as an unmistakably characteristic artefact on the flow audio, was detected 2 min after beginning rapid decompression, or at about 3 atm. gauge chamber pressure. The rate and loudness of these events increased as decompression continued. Within 5 min of the completion of decompression the embolic events had become largely confluent and obliterated most of the flow background. There were momentary periods of total loss of signal probably indicating total inhibition of ultrasound transmission by gas in the vessel. Oscilloscope observations of the tape recorded audio indicated that the peak voltage of most embolic events was at least twice that of the flow background. Using

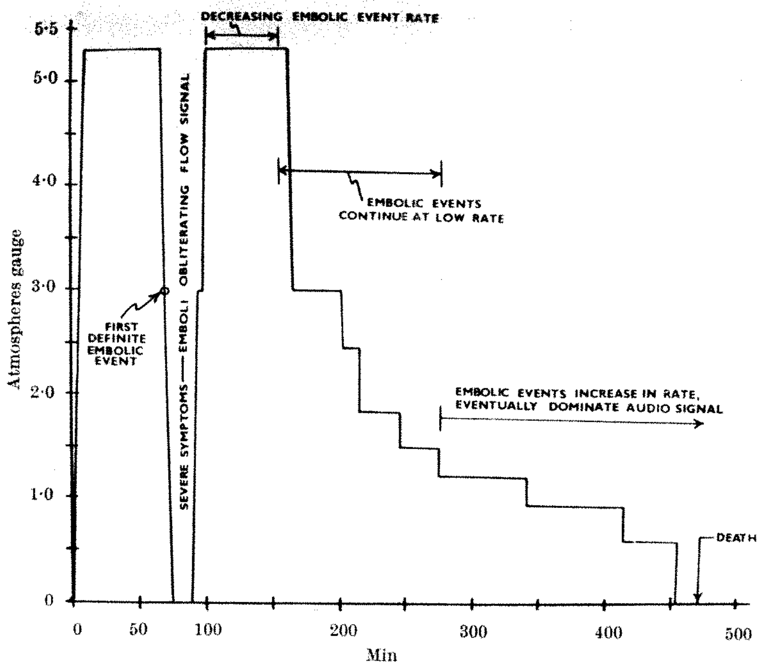

Fig. 1. Chamber pressure against time. Occurrence of embolic events, defined in the text, is described qualitatively.

a triggered sweep with the threshold set above the maximum flow signal, and connecting the vertical gate pulse output to a pen recorder, embolic events could be displayed as shown in Figs. 2 and 3.

The animal was removed from the chamber after decompression and allowed to move freely about the room. Its gait was hesitant and mildly ataxic, with evidence of carpal pain. Increasingly severe ataxia and partial paraplegia appeared within minutes, followed closely by complete collapse. Clonic convulsions and unconsciousness occurred 11 min after completion of decompression.

The animal was returned to the chamber and recompressed to the original level of 5·3 atm. gauge. After about 1 h at this level, only occasional embolic events were detected. There was no significant change in embolic event rate during therapeutic decompression to the 1·22 atm. gauge level, except for occasional embolic "showers" which followed movement of the animal. At the 1·22 atm. gauge level the embolic event rate gradually increased until their signals again obliterated most of the flow background, and continued at this rate to the completion of therapeutic decompression. The animal died about 20 min. later; immediate post-mortem examination showed the entire venous system to be filled with frothy blood.

The conditions of this pilot experiment were extreme, but suggest the potential usefulness of the technique in milder situations. Transcutaneous transducers capable of measuring blood flow in superficial vessels have been in use for some time[4], making the technique immediately applicable to humans. Should circulating gas emboli be detectable by this method before the onset of the subjective symptoms presently used as indicators of decompression sickness, contemporary decompression schedules may require re-evaluation or it can be argued that any gas embolus, regardless of size, is potentially dangerous. The experimental animal will continue to be valuable in more fundamental studies using implanted transducers, such as monitoring gas embolus clearance or

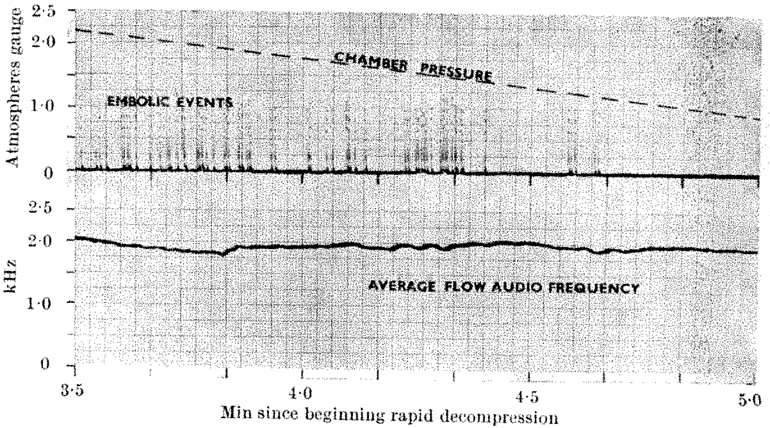

Fig. 2. Simultaneous recording of embolic events and average flow audio frequency during rapid decompression. Chamber pressure is indicated in the upper chart.

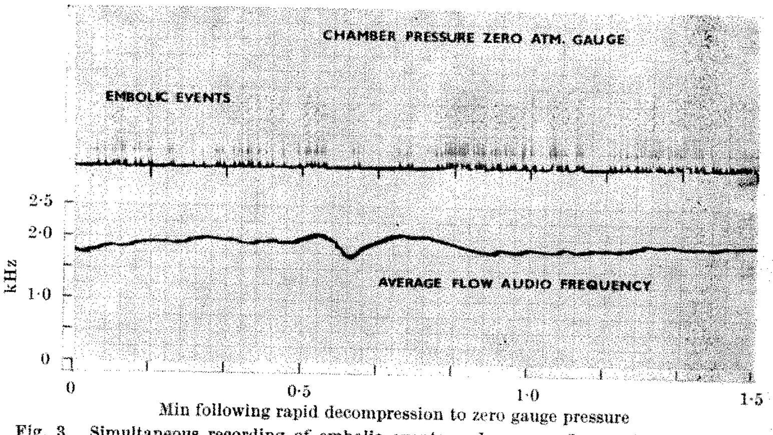

Fig. 3. Simultaneous recording of embolic events and average flow audio frequency immediately after rapid decompression. Note the increased rate of embolic events and absence of appreciable change in vena cava flow rate.

evolution by selected organs The ultimate value of the technique depends on the sensitivity attainable Because this apparatus is designed for measurement of blood flow, changes in design may increase its efficiency for detection of gas emboli The use of artificial emboli of known size should facilitate efforts in this direction as well as aid in the development of more refined discrimination techniques which may permit some degree of quantitation of embolic density or size or a combination of the two

Secretion of 3β-Hydroxypregn-5-en-20-one (Pregnenolone) by the Adrenal Gland

IN a previous communication[1] it was reported that a compound behaving in a manner similar to pregnenolone in several paper and gas chromatographic systems is secreted by the adrenal gland of the dog and pig The same compound was later found in extracts of adrenal glands of these species and of rats[2]

Further evidence for the identity of this compound was obtained by analysis in an LKB 9000 gas chromatograph–mass spectrometer (*GC–MS*) The compound was isolated from adrenal venous blood collected from a female dog under chloralose anaesthesia The purified blood extract was chromatographed first in the E_2B system of Eberlein and Bongiovanni[3], to separate pregnenolone from the principal gluco- and mineralocorticoids, and then in the E_1 system (Eberlein and Bongiovanni[3]) The eluate of the pregnenolone region of this chromatogram was applied to a 3 8 per cent *SE*-30 column (120 cm, 230° C) of an F and M gas chromatograph fitted with a flame ionization detector (260° C) a peak with a retention time of 0 61 relative to that of cholestane was observed (Fig 1) This retention time was equal to that of authentic pregnenolone After acetylation both the peak observed in the blood extract and that of authentic pregnenolone changed their relative retention time to 0 91

A portion of the purified extract of blood was then injected into the *GC–MS* (fitted with a 1 per cent *SE*-30 column at 240° C) The mass spectrogram obtained (Fig 2*a*) shows that the compound has a molecular weight of 316 The spectrum is in satisfactory agreement with that of authentic pregnenolone (Fig 2*b*) Further evidence for the identity of the steroid isolated from adrenal venous blood with pregnenolone was obtained after forming its trimethylsilyl ether The mass spectrogram of this derivative is shown in Fig 3*a* It is in good agreement with the spectrogram of the trimethylsilyl ether of authentic pregnenolone obtained under the same conditions (Fig 3*b*) The molecular weight of the ether is 388 The retention time of the ether formed from authentic pregnenolone on a 1 per cent *SE*-30 column at 240° C was 0 42 in relation to that of the trimethylsilyl

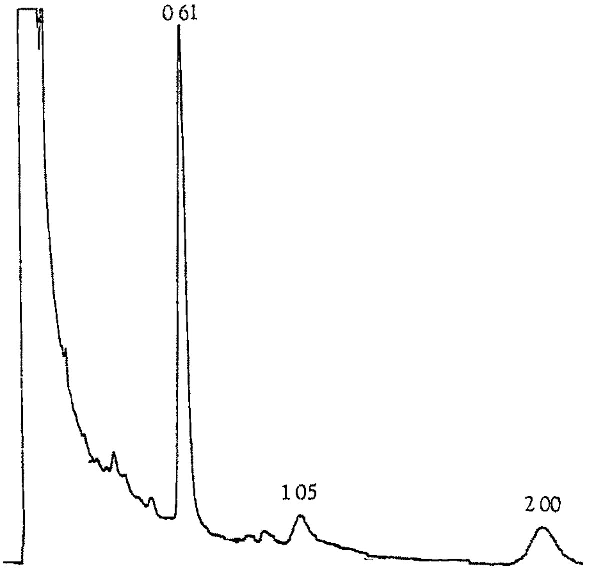

Fig 1 Gas chromatograph tracing of extract from dog adrenal venous blood collected for 30 min and chromatographed in E_2B and E_1 Region with R_F value of pregnenolone eluted, eluate dried, dissolved in 40 μl of ethanol, 1 μl applied to column (range 1, attenuation 8) The number is the retention time relative to that of cholestane Authentic pregnenolone had a relative retention time of 0 61

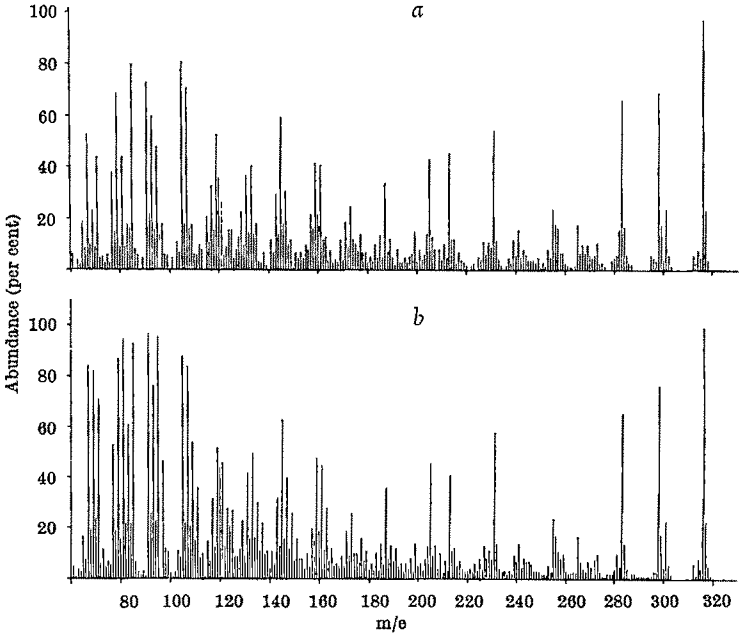

Fig 2 Line diagrams of mass spectrograms obtained with the LKB 9000 gas chromatograph–mass spectrometer (1 per cent *SE*-30 column) *a*, Pregnenolone, separated from dog adrenal venous blood *b*, Authentic pregnenolone

Table 1 SECRETION OF 3β-OH-PREGN-5-EN-20-ONE (PREGNENOLONE) BY THE LEFT ADRENAL OF AN ADULT FEMALE DOG (20 KG) UNDER CHLORALOSE ANAESTHESIA

Experimental conditions	Adrenal secretion rates (μg/g adrenal/h)		Adrenal blood concentrations (μg/100 ml)	
	Pregnenolone	Cortisol	Pregnenolone	Cortisol
Pituitary intact, 30 min after cannulation of adrenal vein	112	715	33 5*	212
1 h after hypophysectomy	6	166	1 9	53
During infusion of ACTH (0 3 mμ/min/kg)	82	690	30 7	260
After ACTH infusion (150 min after hypophysectomy)	4	140	1 4	50

Adrenal venous blood was collected for periods for 30 min from the cannulated left adreno-lumbar vein (Purification and assay as described in ref 1)

* The concentration of pregnenolone in arterial blood collected simultaneously was 0 17 μg/100 ml

ether of cholesterol The same retention time was found for the trimethylsilyl ether of the compound extracted from blood

Pregnenolone was found to be a regular secretion product of the adrenal gland of dogs, puppies and piglets In the dog, it was secreted at an average rate of 100 μg/g adrenal/h in conditions of stress This was about one-tenth of the secretion rate of cortisol Its concentration in adrenal venous blood was in the order of 30 μg/100 ml, whereas its concentration in arterial blood under the same conditions was less than 0 3 μg/100 ml Table 1 shows the dependence of the adrenal secretion of pregnenolone on the presence of the pituitary gland It can be seen that hypophysectomy caused a fall in the secretion of pregnenolone by more than 90 per cent Its concentration in adrenal venous blood, however, was still ten times greater than in arterial blood collected before hypophysectomy This observation indicates that pregnenolone is secreted under resting conditions

The release of pregnenolone from the adrenal gland is not only a function of its concentration in the adrenal tissue In experiments on piglets, decreasing the haematocrit to 4 per cent by infusing dextraven during adrenal blood collection caused a severe fall in the rates of secretion of corticosteroids and also of their concentrations in adrenal tissue The adrenal concentration of pregnenolone was not decreased, however In spite of this, its rate of secretion fell by 85 per cent

The *GC–MS* data were recorded using the LKB 9000 instrument purchased from an SRC grant to Drs C J W Brooks and G Eglinton, Department of Chemistry, University of Glasgow We thank Dr C J W Brooks for arranging for the analysis of the blood extract on this instrument and for evaluating the spectrograms, and also Miss Janice Malcolm who carried out the *GC–MS* analysis, and Miss H Humphrys who drew the line diagrams

Comparative Ultrafiltrability of Calcium and Strontium in Human Plasma

UNTIL recently there have been few and conflicting reports about the comparative ultrafiltrability of calcium and strontium in human plasma Some report that there is no difference[1], others that strontium filters to a greater extent[2] The lack of further experimental data on this subject prompted us to look for differences in the ultrafiltrability of these elements

Ten patients, studied at the time of bone scanning, were injected intravenously with 1–3 mCi of strontium-87m This was obtained from an yttrium-87–strontium-87m generator with 0 005 per cent citric acid, the eluate was sterilized and adjusted with sterile saline to isotonicity with blood plasma Blood samples were taken in anaerobic conditions from the other arm 5–10 min after injection Anaerobic ultrafiltration was carried out on fresh plasma by the method of Lavietes[3] as modified by Smarsz[4] Plasma calcium (Ca_T) and ultrafiltrate calcium (Ca_{UF}) were determined by a standard method[5], and the amounts of strontium-87m in the plasma (Sr_T) and plasma ultrafiltrate (Sr_{UF}) were measured in a scintillation spectrometer, 'Tracerlab *SC* 78', with a counting error not greater than 1 3 per cent The percentage ultrafiltrability of calcium and strontium was calculated from the following formula

$$\text{Percentage ultrafiltrability} = \frac{\text{ultrafiltrable value}}{\text{total value in equal volume}} \times 100$$

The results are shown in Table 1 The percentages of ultrafiltrable calcium and strontium were similar and the ratio of these percentages was almost unity We conclude that the distribution of calcium and strontium in the plasma is similar

These results are of particular importance in calcium–strontium discrimination studies They imply that there is no renal discrimination of strontium against calcium in the glomerulus during filtration, because the filtered plasma water contains the same percentages of calcium and strontium Thus plasma specific activity and the corresponding body retention of radiostrontium can be used instead of radiocalcium to calculate the bone accretion rate, for no real difference in the rate of skeletal uptake of these elements has been found[6]

We thank Dr D J Silvester for the strontium generators, Dr C Smarsz for the ultra-

Environmental Temperature and Plasma Electrolyte Regulation in the Carp, *Cyprinus carpio*

WHILE the ability of the freshwater teleost to control body fluid electrolyte composition has been appreciated primarily in terms of neuromuscular and related membrane-dependent phenomena, an increasing body of evidence points to an equally important role in the regulation of intermediary metabolism[1] Control of water-electrolyte balance in these animals involves adjustment of a variety of passive and metabolically-dependent transfer processes operating at phase boundaries within the body fluid system, and at the several sites at which exchange with the environment is possible Regulation is also influenced by the mass transport activities of the cardiovascular and respiratory systems, the primary functions of which prompt both endosmosis and electrolyte efflux

Adaptation to changes in environmental temperature frequently imposes marked variations in oxygen requirements Satisfaction of these might, *a priori*, be expected to entrain stresses demanding adjustment of the ionoregulatory apparatus In addition, the complexities of the overall regulatory mechanism provide scope for expression of any differential thermosensitivities existing among component elements Despite this, surprisingly little attention has been directed toward this facet of teleostean ionic regulation During a study of systemic aspects of the thermoacclimatory process, we have tried to determine the relationship between temperature and regulatory ability in a typical freshwater eurytherm, the common carp (*Cyprinus carpio*)

Experimental stocks of the animals were obtained by seining and trapping in local waters Holding and experimental facilities and analytical procedures have been outlined before[2] Assessment of regulatory ability was based on determination of plasma osmolarity, and the concentrations of the principal blood electrolytes (sodium, potassium, calcium, magnesium, chloride and phosphate) in groups of animals acclimatized to 4°, 17°, 27° and 33° C for intervals of not less than three weeks

The results of the investigation are summarized in Table 1 It is apparent that both the set-points of regulation (as judged by sample means) and the precision of regulation (as judged from sample variability) are modified by temperature In some cases, the relationships are non-linear Thus plasma sodium concentrations were maximal at 27° C, with a mean concentration of about 9–10 mmoles/l greater than those observed at 4° C and 33° C By contrast, concentrations of chloride increased steadily from a mean of 115 6 mmoles/l at 4° C to 137 0 mmoles/l at 33° C Coupled with this the precision of chloride regulation diminished markedly at higher temperatures Phosphate concentrations increased sharply between 4° C and 17° C, and then diminished slowly, but showed no great change in variability Plasma calcium also increased with temperature from 1 94 mmoles/l at 4° C to 2 54 mmoles/l at 33° C Potassium and magnesium concentrations, on the other hand, displayed no consistent variation in either set-point or precision at the different acclimation temperatures employed

Determinations of blood *p*H were not included in the investigation It is apparent, however, that the ratio *p*Cl/Σ (cation) increased with temperature Taking into account the relationship between phosphate concentration and temperature, and assuming the condition of body fluid electroneutrality, this observation suggests that the concentration of some anionic species, presumably bicarbonate, increases at lower temperatures Accordingly, the occurrence of a condition of essential alkalosis might be predicted in cold-acclimated specimens, an interpretation consistent with the findings of a recent study on acid-base balance in this species[3]

The data suggest a fall in plasma osmolarity at increased temperatures, with a pronounced drop between 27° C and 33° C In contrast, the sum of all cations plus chloride steadily rose with temperature An increasing contribution of non-electrolyte to total osmolarity at lower temperatures is suggested The nature of the materials involved is uncertain Values for total plasma protein levels indicate that it was not protein

While no similar studies on cyprinid fishes appear to have been carried out, information relating plasma composition to environmental temperature is available for a number of salmonids The data are, however, somewhat inconsistent Hickman *et al*[4] report an inverse relationship between plasma sodium and temperature in rainbow trout, while neither Gordon[5] (working on brown

trout) nor Houston *et al* [2] (in investigations on rainbow trout) observed any consistent variation in this ion Hickman *et al* describe an increase with temperature in the chloride levels of 8° and 16° C-acclimated trout A similar situation was noted by Houston *et al* in summer fish of the same species, but not in winter animals A relationship of this type does not appear in the brown trout[5] Increases in plasma potassium were observed by both Gordon and Houston *et al* at elevated temperatures A slight drop in the plasma concentration of this ion was, however, recorded by Hickman *et al* Similarly, the studies on rainbow trout disagree with respect to the relationship between calcium levels and temperature Both rainbow[2,4] and brook trout[6] display increases in total phosphate levels at higher temperature

The significance to be attached to the differences observed in these studies is uncertain It would appear, however, that both the set-points and precision of ionic regulation can be altered by temperature acclimation Nevertheless, recent studies on thermal shock effects[4,7] suggest that the animals are capable of some considerable degree of compensation The functional importance of this is clear with regard to sensory-neuromotor activity, and may be important in terms of metabolic adjustment to temperature as well[1,8]

Pyrogenicity of 'Pyromen'

Wyllie, Limbosch and Nyhus[1], in commenting on the results of Baume, Nicholls and Baxter[2], state that the inhibition of gastric secretion by lipopolysaccharide "was clearly described in 1950" by Blickenstaff and Grossman[3] Blickenstaff and Grossman used 'Pyromen', a commercially available pyrogen (Nesset *et al* [4]), which is very impure and only partially characterized It was for this reason that their results were not discussed by Baume *et al* [2] in their brief communication

'Pyromen' is an extract of *Pseudomonas* obtained from autoclaved cells by tryptic digestion[4] The material represented 25–35 per cent of the cell mass Analyses for nucleic acids, protein and ash accounted for approximately 80 per cent of cell dry weight and 50 per cent of the extract The authors[4] then assumed that the remainder represented pyrogenic polysaccharide From newer methods of extraction it is concluded that lipopolysaccharide represents 1–2 per cent of cell mass rather than the 20 per cent inferred by Nesset and co-workers

The actual amount of lipopolysaccharide in the preparation of 'Pyromen' is difficult to deduce From the chemical analyses no conclusions are possible Studies on pyrogenicity indicated a three-fold increase in activity compared with whole cells which could mean the presence of 5 per cent lipopolysaccharide, but the pyrogenic dose was at least one thousand times greater than that for the purified lipopolysaccharide used by Baume *et al* [2]

From its biological properties, we may presume that 'Pyromen' contains some lipopolysaccharide but, unlike Wyllie *et al* [1], conclude that there is no evidence that the lipopolysaccharide component was responsible for the inhibition of gastric secretion In contrast, Baume *et al* [2] used a purified lipopolysaccharide which has been fully characterized[5], and was made available in a water soluble form[6] This left no doubt that the effects on gastric acid secretion were caused by the lipopolysaccharide

Permeability and Excitation of Insect Muscle

The membrane of most nerve and muscle cells is assumed to be more permeable to potassium ions than to sodium ions in the resting condition and the potential observed approaches that of a potassium electrode as predicted by the Nernst equation The plasma membrane becomes much more permeable to sodium ions during excitation, and the potential across the membrane reverses, producing a positive overshoot of the action potential The skeletal muscles of herbivorous insects, however, have unusual bioelectric properties and have been studied by Wood[1–4] and Huddart[5–7] Analysis of the haemolymph and myoplasm of Orthoptera, Dictyoptera and Lepidoptera reveals an unusual ionic distribution[8] and it is suggested that the observations of the resting and action potentials fail to agree with the values predicted by the Nernst equation and with the classical studies of excitable cells For example, frequently no positive overshoot to the action potential has been recorded It has been suggested that active transport of chloride ions may contribute to the resting potential[4], and that an inward movement of sodium[9] or magnesium ions[1,9] may participate in the action potential Our present knowledge in this field has been reviewed by Aidley[9]

If sodium ions enter the cell during the action potential some system must be present to remove them A sodium–potassium–magnesium–ATPase has recently been found in the plasma membrane of many tissues of other species and is believed to be associated with active cation transport[12] A study of the enzyme properties of the muscle membrane of herbivorous insects could represent the first step in establishing which ions move and carry the ionic current during excitation

Cockroach (*Periplaneta americana*) coxal muscle was therefore studied to determine whether a sodium–potassium–magnesium–ATPase was present in a microsomal preparation The muscle microsomal fraction was prepared according to experimental details given elsewhere[10] except that the isolation medium contained 10 mM EDTA ATPase activity was determined as the inorganic phosphorus liberated[11] in 15 min at 25° C, the reaction being linear during this period Other conditions of incubation are given in Table 1, in which the results of two representative experiments are summarized It can be seen that the magnesium–ATPase activity constitutes much of the total activity, addition of either sodium ions or potassium ions increases this activity, although sodium ions have been found to be consistently less effective than potassium ions. When sodium and potassium ions are, however, added together, little or no synergistic action was found; indeed, higher concentrations of sodium ions inhibited the potassium–magnesium–ATPase activity Strophanthin-*G* at high concentration (10^{-4} M) had only a small inhibitory effect on the activity that was stimulated by the addition of monovalent cations Thus there is little genuine sodium–potassium–magnesium–ATPase (with an obligatory requirement for both sodium and potassium ions[12]) in this preparation and, furthermore, we have found that the monovalent cation-stimulated fraction of the ATPase activity is suppressed by extraction with DOC, a treatment which usually increases the ratio of sodium–potassium–magnesium–ATPase magnesium–ATPase activity in mammalian tissues[12]

These results can be directly compared with those obtained with a microsomal preparation from cockroach nerve cord[13], where a genuine sodium–potassium–magnesium–ATPase, which is sensitive to strophanthin-*G*, constitutes 75 per cent of the total ATPase activity Thus while the monovalent cation-stimulated ATPase found in the muscle microsomal preparation might be concerned with the active transport of cations, its properties are clearly very different from those of the nerve cord from the same animal, and also from those described in mammalian tissues[14] (although compare frog muscle[15]). It is therefore possible that there is little requirement for the active outward extrusion of sodium ions across the muscle membrane, and the view that sodium ions do not enter during excitation is supported by the observation that $[\mathrm{Na}_i^+]>[\mathrm{Na}_o^+]$ in the muscle of some species of insects[7].

There may well be a wide variation in the underlying mechanisms accompanying excitation of muscle in herbivorous insects, but the following hypothesis is tentatively advanced to account for some of the observed phenomena. THE RESTING POTENTIAL in *Bombyx* muscle fibres sodium ions (as well as potassium ions) are more concentrated intracellularly than in the haemolymph[7] (compare squid and vertebrates) while chloride ions are more concentrated in the haemolymph[7] This ionic imbalance is presumably maintained by organic anions inside the fibre, and possibly assisted by organic cations in the haemolymph[16] It seems clear that the resting potential is the resultant of the differential permeability of the membrane to potassium and chloride ions[17], although sodium ions may have an additional effect, augmenting the potential where $[\mathrm{Na}_i^+]>[\mathrm{Na}_o^+]$ and reducing it when the concentration gradient is established in the opposite direction.

THE ACTION POTENTIAL could be the result of (i) An inward movement of sodium ions in some species, although such an explanation is not tenable for muscles (for example, *Sphinx*, *Telea*, *Bombyx*, *Actias*) where $[\mathrm{Na}_i^+]>[\mathrm{Na}_o^+]$ (ref 7). The atypical and low specific activity of the monovalent cation-stimulated ATPase of the cockroach muscle (where $[\mathrm{Na}_o^+]>[\mathrm{Na}_i^+]$ (ref. 3)) also suggests that the movement of sodium ions may contribute little to the action potential (ii) An inward movement of magnesium ions The magnesium–ATPase found in the microsomal preparations in these experiments would then act in the subsequent active transport of these ions outwards Such a hypothesis is also unlikely to be the complete explanation (*a*) $[\mathrm{Mg}_o^{2+}]$ is low in some species (only 1 4 mequiv /l in *Anabrus*)[18], (*b*) the action potential of *Carausius* persists when $[\mathrm{Mg}_o^{2+}]$ is reduced to zero[1], (*c*) there is evidence that some of the $[\mathrm{Mg}_o^{2+}]$ is bound to organic molecules in the haemolymph[19]; and (*d*) in *Calliphora* larvae, no exchange of magnesium ions takes place when the muscle membrane permeability is artificially increased in heat death (personal communication from T F Davison)

We therefore suggest that, after excitation, the action potential is produced by a transient, simple decrease in permeability of the muscle membrane to the diffusible ions (potassium, chloride and possibly in some species sodium), so that the membrane is depolarized and the resting potential approaches zero Such a system requires no form of active transport We visualize the magnesium–ATPase found in our preparation as being a contractile protein which is sited at the membrane pores and which controls the diameter/charge relationships there[10,20] There would therefore be a change in potential across the muscle membrane at the multiterminal endings, and excitation would spread decrementally to the local sarcoplasmic reticulum. The change in membrane potential possibly initiates muscle contraction by a displacement of bound calcium ions from the endings of the sarcoplasmic reticulum

Such a hypothesis is almost certainly not the complete explanation of the complex events observed during the excitation of these muscles, but the production of a depolarization by a decrease in permeability would serve to explain many of the phenomena observed in these insects. Where an active membrane response, with a small positive overshoot, is superimposed on this basic endplate potential, however, other ionic factors must be involved This may well be an inward movement of magnesium or calcium ions

The permeability of all excitable cells is controlled by a dynamic system, but in most excitation is achieved by opening "gates" for sodium ions to enter[20] Our suggestion for the membrane of the muscle of herbivorous insects involves a more fluid control of passive permeability which controls both the resting potential and the changes in permeability during excitation It is interesting that temperature changes have small effects on the resting potential of crab and frog muscles ($Q_{10} = 1\ 06$), whereas the Q_{10} for cockroach muscle is higher at 1 296 (ref 21). This marked effect of temperature is much higher than would be predicted by a simple application of the Nernst equation

Communication in the nervous system of these insects, however, necessitates genuine, non-decremental, propa-

Enzyme activity expressed as mμmoles of inorganic phosphate liberated/mg of protein/min Effect of the addition of alkali metal ions is shown as the additional enzyme activity found above that in the presence of 4 mM magnesium ions alone (Experiments *A*1 or *B*1*a*) No correction is made for the small activity found in the presence of sodium or potassium ions alone (experiments *A* 3–6) Enzyme activity sensitive to strophanthin-*G* is calculated as [a–b–(1a–1b)] Conditions 2 mM ATP (*tris* salt), 50 mM *tris*-HCl (*p*H 7 2), 25° C gated transmission and therefore a typical permeability increase (probably to sodium ions) can be predicted in nerve cells[22] An appropriate transport sodium-potassium-magnesium-ATPase has been identified in cockroach nerve cord[13] The need for this form of excitation may explain the presence of the sheath and compartments around the insect nerve cord, which serve to isolate it in its appropriate ionic micro-environment[23,24]

PSYCHOLOGY

New Method of Testing Long-term Retention with Special Reference to Amnesic Patients

A specific isolated and severe defect of memory, with preservation of other intellectual functions, including span of attention, may occur as the result of localized brain pathology In amnesic patients the memory defect is so marked that performance on tests of recent memory declines sharply within a matter of minutes[1]

Because normal subjects show excellent retention on a test which we devised, it seemed interesting to find out whether amnesic patients would show day to day retention on it This communication describes the technique and reports results showing day to day retention in a series of amnesic patients The findings are considered in relation to some theoretical issues

Milner[2] reported that maze learning in one severely amnesic patient with bilateral hippocampal lesions was impaired on the easiest form of the test, that there was some learning within a test session on one day, and some evidence of retention between days In contrast she also reported that a motor skill, mirror drawing, was learnt at a normal rate So far, however, there has been no clear demonstration of day to day retention of pictorial and verbal material by severely amnesic patients

The subjects of this experiment were six patients with a severe and circumscribed memory defect, and five patients with peripheral nerve lesions who had no known

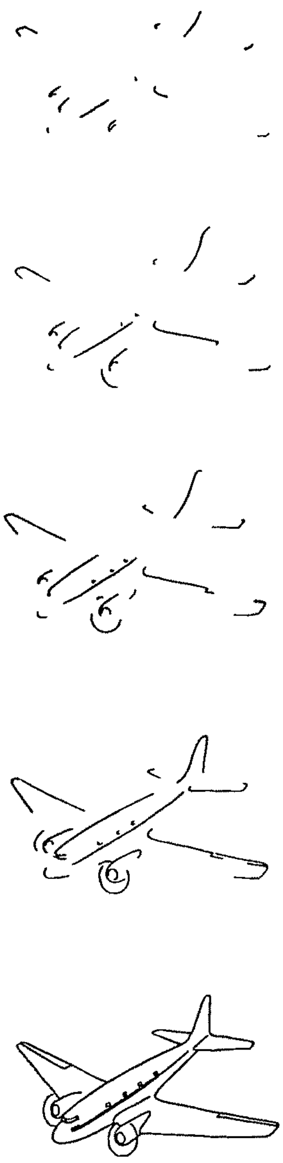

Fig. 1. Example of incomplete picture (from Gollin's[4] series)

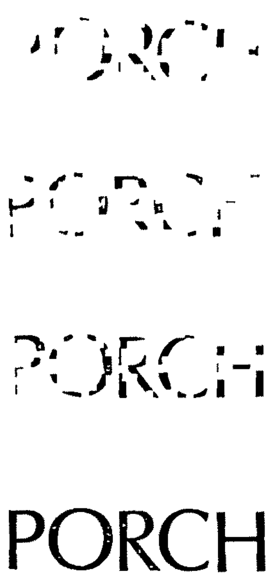

Fig 2 Example of incomplete word

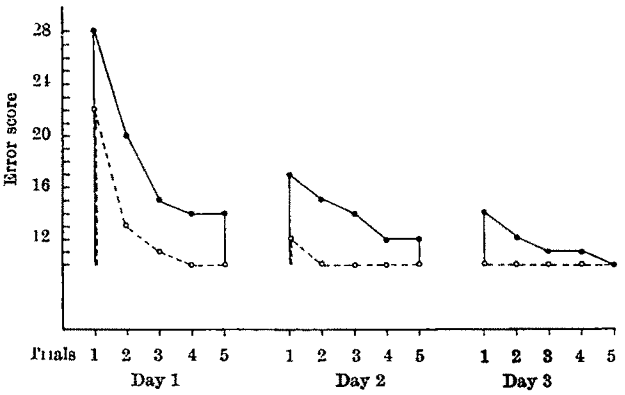

Fig 3 Mean error scores for each trial, for each patient group, on the incomplete picture test ●—●, Amnesics, ○ - - - ○, controls

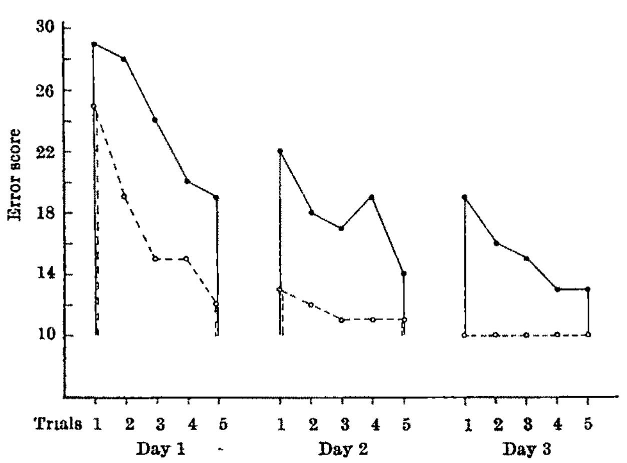

Fig. 4 Mean error scores for each trial, for each patient group, on the incomplete word test ●—●, Amnesics, ○ - - - ○, controls

cerebral disease The six amnesic patients all had intelligence quotients not less than average, as had the control group, and the ages of the two groups were also matched The amnesic patients were all unable to recall day to day events and had retrograde amnesias which, as far as could be determined clinically, varied in length from 10 to 30 yr Five of these amnesics were patients with alcoholic Korsakoff psychoses, and the other (N T) became severely amnesic after a right temporal lobectomy This case has been described in detail by Dimsdale, Logue and Piercy[3]

In 1960, Gollin[4] prepared a graded series of fragmented drawings There are five versions of each drawing, the first being very incomplete, and the fifth being a complete representation of the object, with three intermediate versions (Fig 1) Ten sets were used for this experiment

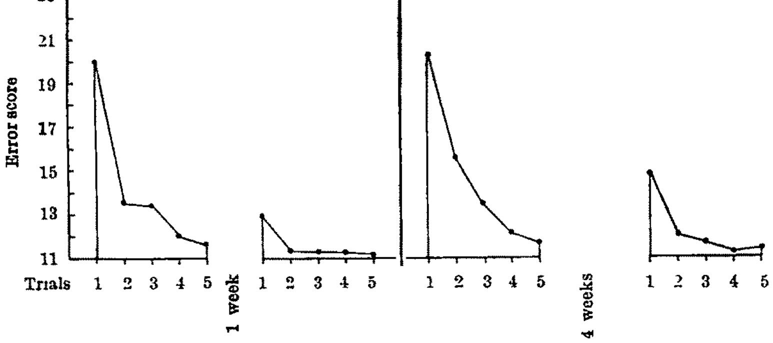

Fig 5 Mean error scores for each trial in normal subjects Group I ($N = 8$) were re-tested after 1 week, and Group II ($N = 10$) after 4 weeks

We also prepared a series of graduated incomplete words Five letter words, all of high frequency in the Thorndike–Lorge word count, were photographed through patchwork filters of varying density Ten sets were prepared, with three incomplete versions of each word (Fig 2)

A testing situation was devised in which the recognition of incomplete pictures and words could be used as a measure of learning and retention The most incomplete drawing was presented first, and then the succeeding versions, until there was a correct recognition or identification A recognition error score was established on the first trial and the series was immediately repeated and the reduction in errors noted. All subjects were tested on 3 successive days, five trials were given on each day The total error score on each trial was recorded The ten sets of each test were always presented in the same order, each subject doing the incomplete pictures first The incomplete word test was done by two amnesics and two controls immediately after the incomplete picture test Two amnesics and two controls were further tested, starting on the third day, using the same procedure with an equivalent but new series of incomplete pictures

The mean score for each trial for each group of patients on the incomplete picture test is shown in Fig 3, and for the incomplete word test in Fig 4 It is evident that learning proceeded rapidly and smoothly in both control subjects and amnesic patients, although the amnesics were slower The controls showed almost perfect retention 24 and 48 h later The amnesic group, although impaired in comparison with the control group, nevertheless showed retention on the second and third days For both types of material the scores obtained on the second and third days were better than at the starting point of the previous day, that is, in re-learning some saving was demonstrated

Two amnesic and two control patients were tested on a new but equivalent series of incomplete pictures The performance was comparable with their original scores in terms of initial speed of learning and retention between days It cannot therefore be argued that the improvement within days and the retention between days reflect a non-specific sensitization for similar types of material—that is, that the subjects simply became better at "guessing" independently of the specific content of the test

Retention and re-learning over an interval of 1 week and 4 weeks in a group of eighteen normal subjects for incomplete words (eleven sets) is shown in Fig 5, which demonstrates that retention is good over relatively long periods One amnesic patient (N T) was re-tested on the incomplete pictures after an interval of 3 months, comparing the summed error scores for the first five trials on each occasion, there was a saving of 20 per cent after 3 months

In amnesic patients, the striking aspect of the results is the excellence of retention between days The words, all of high frequency in the Thorndike–Lorge test, were also used in more conventional tests of recall and recognition, and very poor retention was found after delays as short as 5 min[5]

Meanwhile, it is clear that evidence for some (if incomplete) retention from day to day can be found in severely amnesic patients, and therefore the characterization of their defect as a rapid decay of traces is not easy to maintain, and the hope[6] that the rapid forgetting curves of amnesic patients could be used to generate the shape of the short-term trace seems forlorn in the face of the evidence reported here

Significant retention from day to day by amnesic patients has been reported for motor tasks, simple stylus mazes and stories[1,2] and now for the present type of task The question whether these tasks have anything in common other than being favourable for good retention in normal subjects remains to be seen Measurable retention is certainly not restricted to examples in which each learning trial can be encompassed by the immediate memory span, as suggested by Milner[2] for her simple stylus maze, because our perceptual tasks exceeded the immediate memory span.

Talland[1] and Williams[7] used a similar approach to investigate recognition in patients with cerebral dysfunction, and found that pre-exposure to fragmented drawings or "perceptual prompts" improved performance There are several features which distinguish this type of test from more conventional memory tests, and at this stage one can only speculate as to which factors are important in accounting for the difference in performance Further work is planned to elucidate this question. It is, however, worth mentioning that in addition to the rapidity and uniformity in learning this task, patients find it a much less exacting test than more conventional ones They treat it more as a "guessing game" than a formal test of memory. The test might therefore commend itself for use with a broader class of patients

We thank Dr R. T. C Pratt for providing facilities to carry out this work and for advice in the preparation of the manuscript

CYTOLOGY

Mitotic Activity in the Primate Subependymal Layer and the Genesis of Gliomas

Globus and Kuhlenbeck[1,2] drew attention to the presence beneath the lining of the cerebral ventricles of a distinct cell layer, which they named the subependymal cell plate They demonstrated it in the brain of human infants, showed it to contain primitive cells and stressed its possible role in the development of certain paraventricular neoplasms Various workers[3–5] have shown the persistence of a subependymal layer in man from foetal to adult life, but except for explaining the origin of "subependymomas"[6] the idea that this zone plays a part in the genesis of gliomas has met with little support

A mitotically active and well-defined subependymal layer is present in mammalian brains throughout life Allen[7] and Bryans[8] described mitoses in the lateral ventricular wall of adult rats Smart[9] used autoradiography to demonstrate proliferation of subependymal cells in the young mouse and their transformation into mature neuroglia, and Altman[10] has shown this to occur in cats Fischer[11] examined the brains of dogs aged up to 17 yr and found subependymal mitotic activity, and this phenomenon is thus common to different species at all ages

According to Kershman[12] the subependymal plate is a source of neurones and glia in early life In the embryo it is formed from the ependyma as a broad layer of neuroblasts and spongioblasts and it decreases in thickness in later foetal life, persisting after birth only as a thin, discontinuous lamina. In adult rodents the subependymal plate is situated in a rostral and dorsal position, with an extension into the olfactory lobe[9], its cells exhibit morphological (unpublished work of W. B Blakemore) and histochemical[13] signs of immaturity, show frequent mitotic figures and can divide and migrate away from the ventricle[10]

To what extent is the human subependymal layer comparable with this active and proliferative plate? Although many of the cells underlying the infant's ventricular surface are refractory to glial stains and are therefore considered to be immature[2], the presence of mitoses in this region has not been shown after birth Mitotic figures are seldom if ever seen in post-mortem cerebral tissue or non-tumour biopsy material from the brain[14].

An important reason for this is that fixation by immersion, the method commonly employed, allows many mitoses which have begun before death to go to completion, because diffusion of fixative through a piece of tissue may take longer than the mitotic cycle, which lasts between about 30 and 150 min in mammalian species[15]. In 1960 Cammermeyer[16] introduced perfusion fixation into neuropathological practice, with this technique virtually instantaneous brain fixation can be achieved and post-mortem changes can be reduced to a minimum This has led, among other things, to a reassessment of concepts of cell multiplication in the brain Lapham[17] provided evidence to support the idea that reactive neuroglia divided by amitosis· while this may occur, it is now recognized that mitosis is the usual method of division in glia[18,19].

The apparent absence of mitoses in the human brain is an obstacle to the equating of the rodent with the primate subependymal layer, as well as to the acceptance of Globus and Kuhlenbeck's theory of the origin of certain gliomas, and so this study was carried out on the brains of monkeys fixed by perfusion Sections were examined microscopically for evidence of cell proliferation in the subependymal region

Five young (less than half grown) monkeys were killed with 'Nembutal' and decapitated, and their brains were immediately perfused through the carotid arteries with 1 per cent formol-acetic acid solution, perfusion continued for 30–40 min Coronal brain slices were made through the head of the caudate nucleus, the rostral part of the thalamus, the anterior commissure and the optic chiasma, and five paraffin sections of each slice, stained with haematoxylin and eosin, were scanned with a × 90 oil-immersion objective for mitoses in the paraventricular region. Sections of midbrain and hindbrain from one monkey were also examined

The findings were similar in all five animals A distinct subependymal layer is present in the monkey as a discontinuous band of cells beneath the surface of the ventricles, separated from the ependyma by a fibre layer of variable thickness It is most marked anteriorly in the lateral ventricles and is tenuous and sometimes difficult to recognize posteriorly and in the wall of the third and fourth ventricle and the aqueduct In addition to astrocytes and microglia the layer contains cells of an unusual type, with nuclei measuring 5·0–6 0μ × 3 5–4 5μ and profuse finely stippled chromatin without marginal clumping or a definite nucleolus, as in microglia These cells are most numerous in two prolongations of the subependymal layer in the anterior part of the brain, one dorso-lateral and spreading from the angle of the lateral ventricle between the undersurface of the corpus callosum and the caudate nucleus, and the other ventral and passing below the head of the caudate to the olfactory area Here the cells are often in nests, which are sometimes related to small blood vessels

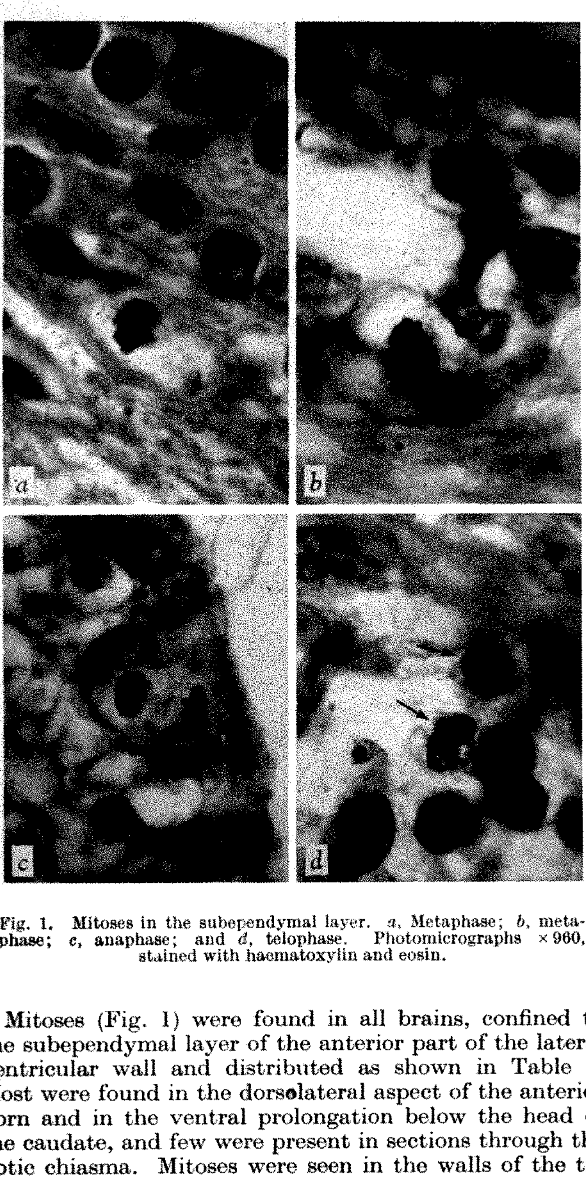

Fig. 1. Mitoses in the subependymal layer. *a*, Metaphase; *b*, metaphase; *c*, anaphase; and *d*, telophase. Photomicrographs × 960, stained with haematoxylin and eosin.

Mitoses (Fig. 1) were found in all brains, confined to the subependymal layer of the anterior part of the lateral ventricular wall and distributed as shown in Table 1. Most were found in the dorsolateral aspect of the anterior horn and in the ventral prolongation below the head of the caudate, and few were present in sections through the optic chiasma. Mitoses were seen in the walls of the tip of the temporal horn in three monkeys.

Table 1. DISTRIBUTION OF MITOSES IN THE SUBEPENDYMAL LAYER

Monkey	Sex	Weight (kg)	No. of mitoses in lateral ventricular wall					
			Dorsal	Lateral	Medial	Ventral	Temporal	Total
Patas 1	M	2·9	2	12	0	2	1	17
Patas 2	M	2·6	3	9	0	6	1	19
Patas 3	M	2·5	2	3	1	9	0	15
Patas 4	F	2·5	0	11	0	2	1	14
Cynomolgus	?	2·5	0	2	0	7	0	9

These findings suggest that the rodent and primate subependymal layers are homologous. Their distribution is similar, with thickenings of the periventricular layer extending between the caudate nucleus and the corpus callosum and in the wall of the remnant of the obliterated olfactory ventricle, rostral in the rodent[9] and ventral in monkey and man. In addition they have similar histology and contain, besides active astrocytes, characteristic immature cells with small dark nuclei, distinguishable ultrastructurally from microglia (unpublished work of W. B. Blakemore) and frequently lying in small nests[20]. The number of mitoses per section is considerably smaller in the monkey than in the rat. This may reflect the relatively diffuse nature of the subependymal layer in the primate and explain why Noetzel and Rox[20] did not find selective uptake of tritiated thymidine in this zone in rhesus monkeys.

Does similarity in structure imply similarity of function? In newborn rats[21] and mice[9] subependymal cells divide, migrate and mature into neurones and glia. An autoradiographic study of adult rats (my unpublished work) provides evidence that astrocytes, oligodendroglia and microglia are derived from the cells of the subependymal layer, which are thus primitive and pluripotential. The weight of the rat's brain increases throughout life[22] and the marked subependymal proliferation in rodents may be an indication of ever-increasing glial number. In man, adult brain weight is reached by the time of adolescence[23] and the relatively low mitotic index may be a sign of a smaller degree of neuroglial proliferation. The pluripotential nature of the subependymal cells suggests that they could be a possible source of different histological varieties of glioma, in particular those tumours in a paraventricular situation and "butterfly" gliomas of the corpus callosum. A scrutiny of these neoplasms in the light of the present findings may lead to a reappraisal of Globus and Kuhlenbeck's theory.

I thank Professor J. B. Cavanagh for guidance and Dr V. Udall for the monkey brains.

BIOLOGY

Integumental Pigments of the Millipede, *Polydesmus angustus* (Latzel)

So far little is known about the tissue pigments of the myriapods[1], except that there is xanthommatin or a nearly related ommatin in some iulids[2] and a water-soluble, violet pigment in some opisthogoneates[3]. The polydesmids, although rather closely related to the iulids, contrast sharply in morphological details and colour, which prompted this investigation of the integumental pigments of *P. angustus*. These differ from those of *Iulus* even more than anticipated.

The animals were eviscerated and divided into pieces two or three metameres long. Treatment with such solvents as acetone indicated that there were no significant amounts of common lipochromes and so the same sequence of extractants was used as for the tissue pigments of leeches[4]: that is, water, 0·1 N HCl, N HCl and finally N HCl in absolute methanol. These extractants seemed to extract with increasing efficiency each of the three pigments recognized; MeOH–HCl eventually removed all detectable colour from the carcass.

Two chief pigments were found, both pink in colour, as well as a yellow minor constituent. An intense crimson fluorescence in ultraviolet light was associated with one of the pink pigments, which seems to be coproporphyrin. The other pink pigment is probably a derivative of this porphyrin, such as a porphyran (metalloporphyrin) or a complex of this with a nitrogen compound (for example, a haemochrome); it retains the Soret absorption band but lacks the ultraviolet fluorescence. Porphyrins and their derivatives have not previously been found as integumental pigments in arthropods. Usually there was no trace of fluorescence in the living animal so that the porphyrin is probably protein-bound *in situ*.

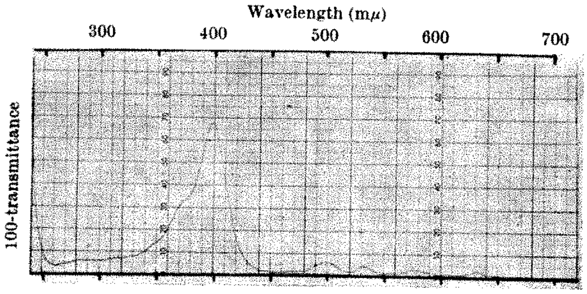

Fig. 1.

The principal peaks in its absorption spectra (Fig. 1) in various solvents were as follows: 283, 403, 551 and 593 mμ for N HCl; 282, 398, 498, 530, 572 and 627 mμ for diethyl ether; 401, 499, 533, 568 and 625 mμ for chloroform; 382, 396, 498, 534, 563 and 614 mμ for N KOH. Some of these values differ in detail from published figures for coproporphyrin[5–7], but the colour is that of coproporphyrin and the "HCl-numbers" of the free porphyrin and its methyl ester were found to be 0·1 and 1·8 per cent, respectively, which are near the expected values for coproporphyrin.

The porphyran was best isolated by partitioning into carbon tetrachloride from methanolic HCl, or into ether from aqueous HCl by cautiously adding sodium acetate, insufficient to drive up the free porphyrin. In CCl_4 its absorption spectrum (Fig. 2) showed peaks at 335, 402, 528 and 567 mμ, that at 402 mμ being a typical Soret, much sharper and more intense than the others, and virtually in the same position as that of the porphyrin in chloroform. The positions of the other peaks, however, differed by 10 mμ, or more, and that at 567 mμ was higher than that at 528 mμ. In ether the Soret peak was at 398 mμ, again in the same position as that of the porphyrin, and the others were at 526 and 564 mμ. In both solvents there was also a peak at 333 mμ. The suspicion that it is a derivative of the porphyrin, of the type suggested, was confirmed by the appearance of the typical porphyrin ultraviolet fluorescence on treatment with concentrated H_2SO_4. The absorption spectrum in dilute H_2SO_4 was virtually identical with that of the native porphyrin in HCl. The artefact porphyrin partitioned into ether, using the sodium acetate method, and in this solvent the spectrum was again identical with that of the native porphyrin.

The porphyran closely resembled protoferrihaem[4] in partitioning directly into CCl_4 from methanolic HCl, without adding water, and iron could be detected, using *iso*-amanol to increase the sensitivity of the familiar ammonium thiocyanate test[8]. This *Polydesmus* pigment therefore is probably a coproferrihaem derivative, if not the ferrihaem itself. It differs from protoferrihaem[4] in retaining, scarcely shifted or otherwise modified, the Soret peak of the free porphyrin. The high solubility in such a relatively apolar solvent as CCl_4 rules out any very hydrophil nitrogenous conjugant, particularly any large molecule such as a protein.

This association between a porphyrin and its non-fluorescent derivative, as integumental pigments, resembles that between protoporphyrin and its ferrihaem in earthworms[4], where the porphyran sometimes contributes most of the visible colour. The present derivative, however, is almost as delicately coloured as the free porphyrin, as indicated by its very low peaks in the visible range (Fig. 2). In the tissues of polychaetes, again, porphyrins in association with their iron porphyrans are very common[7], and the copro III pair are perhaps the most widespread.

It is difficult to free the *Polydesmus* porphyrin completely of the porphyran, although the latter is relatively easily obtained quite free of the porphyrin; that is, of the red ultraviolet fluorescence. After two passages from HCl solution to ether and back, with thorough washing at each stage, there was still demonstrable iron present, although the amount did decrease by a large factor at each stage. Also at each stage non-fluorescent pigment was left behind. Protoporphyrin appears to be more easily cleared of protoferrihaem.

The yellow pigment remained in aqueous media after driving out the porphins, and it was possible to partition it into butanol, carbon tetrachloride and ether. It had a relatively sharp peak in light absorption at 459 mμ, in all of these solvents and in methanolic HCl, and it may also have spectral features in the ultraviolet range. A moderate blue-white ultraviolet fluorescence was associated with it, and furthermore it showed some resemblance to a water-soluble yellow pigment extracted from *Hirudo* and other leeches[4], which may be a porphyrin derivative. The present pigment may therefore be related to the two porphins. The peak in light absorption at 459 mμ is near that of xanthommatin[2], but this pigment did not show the characteristic redox colour change of the ommatins. Reciprocally the iulids examined have yielded very little porphyrin—in fact, less than most invertebrates—whereas *Polydesmus* has an unusually high content. The two diplopods thus further emphasize the fact that the integumental pigments of animals vary more than most classes of biochemical materials, particularly in the lower taxa. For comparative biochromatology, it is therefore not enough to study a few species in each phylum.

Like the other tracheate arthropods, *Polydesmus* has no evident circulatory pigment and the presumption must be that its integumental porphins are synthesized in the same pathway as are the cytochromes and other tissue haemoproteins. This pathway does not usually produce such large amounts of by-products and the polydesmid integumental pigments would seem to have become an end in themselves.

In conclusion, the integumental pigments of *Polydesmus* are (*a*) coproporphyrin, (*b*) a non-fluorescent derivative

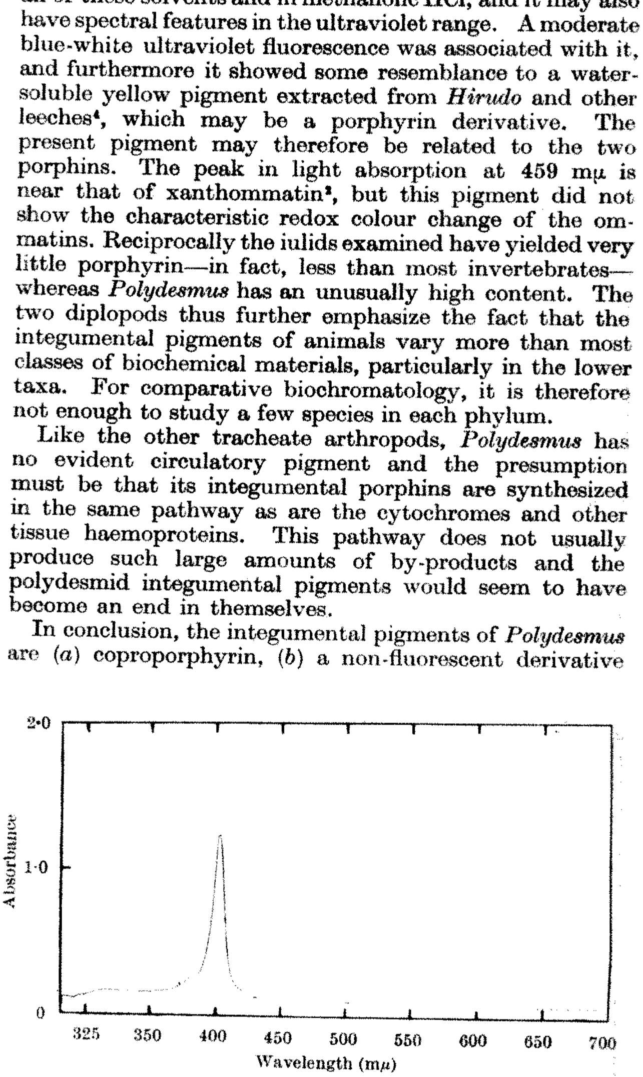

Fig. 2.

soluble in carbon tetrachloride, and (*c*) a yellow pigment, possibly a derivative of the same metabolic pathway.

Familial Behaviour of *Tilapia* (Pisces, Cichlidae) and its Implications

Two types of familial organization are known in *Tilapia* and in cichlid fishes in general[1]. In the biparental type, which is considered to be the more primitive[2,3], both partners participate in digging the nest and defending the territory. The eggs are deposited on the ground ("substratum spawners") and both parents take care of them and of wrigglers and fingerlings for days or even weeks. Hundreds of young form a group which stays within the limits of the territory, and which is kept together by special movements of the parents. The bond between the parents is very strong[4,5].

In most oral incubators, different males in a number of territories are successively visited by different females, whose eggs are thus fertilized in small batches[6]. As soon as a male has emitted his milt, the eggs are picked up in the female's mouth and she leaves the territory and retreats from the spawning ground to another area where she incubates the eggs orally. When they have absorbed their yolk sacs, the fingerlings can swim about freely, but they stay in a group near the female, following all her movements and retreating into her mouth when there is danger. By this time this familial group has generally reached shallow waters sheltered by plants.

Recent work[7] has revealed something of the nature of the bond between the young and their parent(s). Batches of young fish, reared without parents, were exposed at different times to moving models. At about the age at which the rejection normally occurs the young of both *T. mossambica* Peters and *T. macrochir* Blgr., both of which are maternal brooders, immediately showed an orientation and following response when exposed to the moving model. This response was established at the time when the yolk sac was nearly reabsorbed (9–12 days after spawning) and was maintained until the time at which the young usually become independent of their mother (30 days after spawning). If, however, the first exposure was made later (22–23 days after spawning), it was impossible to evoke a positive reaction; on the contrary, fear and escape behaviour occurred. This indicates that there is a precocious sensitive period for the establishment of the familial attachment which suggests that young are really imprinted in maternal-brooders.

In species of the biparental familial type (*T. guineensis*) territorial behaviour is shown until the young become independent; fingerlings do not show such an innate disposition to form a precocious attachment to the first moving object they meet. They can learn to follow a model, but only after several hours' exposure, so that it is impossible to determine the learning process responsible for the establishment of the attachment. Finally, in *T. galilaea* the young react towards the moving model in a manner similar to *T. guineensis*. From an ethological point of view, this species is intermediate between the two principal ethological groups: both parents incubate the eggs and the fry orally, but they are territorial until the young become independent.

In substratum spawners, the young are born and develop at the place where their parents met, and they seem to be more linked to the territory and the substratum itself than to their parents. On the other hand, with females which incubate their young orally the young do not know the habitat where their parents met, for they are born away from the spawning ground. It is essential therefore for the young to be strongly linked to the incubating parent so that they can follow this parent when it moves.

We can assume that the acquisition of oral incubation and both peregrinating behaviour in the incubating parent and imprinting in the young represent a progressive step resulting in a greater independence of the fish from one type of habitat. This facilitates adaptive radiation, which in turn facilitates speciation. Most *Tilapia* species are known to be oral incubators, and only a few are substratum spawners[2,3].

In African waters where water level is periodically lowered, as in artificial lakes producing hydroelectric power, the substratum spawners are often obliged to leave their territory, whereupon the eggs and the fry are destroyed and dried up. If they are free-swimming fingerlings, they stay within the limits of the territory and do not follow the retreating parents. On the other hand, there is no danger to the oral incubators, because the females leave the spawning grounds in search of deeper waters with their eggs and fry in their mouth and retreat with their fingerlings[8]. We know that the water levels of several African natural waters, such as Mweru Wantipa[9], are sometimes lowered; oral incubator species are better armed to face these fluctuations. With this in mind it has been suggested that ponds or artificial lakes which show fluctuations of water level should be charged with oral incubators only[8].

Mitotic Chromosomes of *Glossina pallidipes* Austen

THE chromosomes of several species of tsetse-fly have been studied by Itard[1]. These include *Glossina tachinoides* Westwood and *Glossina morsitans orientialis* Vanderplank (*Glossina morsitans morsitans* Westwood in the terminology adopted by Itard). *Glossina morsitans orientalis* is one of the two main tsetse-flies which occur in Rhodesia, and so I thought it worthwhile for comparison to study the other, *Glossina pallidipes* Austen. The *G. m. orientalis* material used by Itard originated in Rhodesia.

Glossina pallidipes puparia were supplied by Dr R. J. Phelps and G. J. W. Dean of the Agricultural Research Council in Rhodesia. This material originated from collections of puparia from natural pupation sites near Kariba Township in the Zambezi Valley. The puparial contents were thus aged from 24 h (the time from the last collection to the arrival of the puparia at the laboratory) upwards, although the exact age of

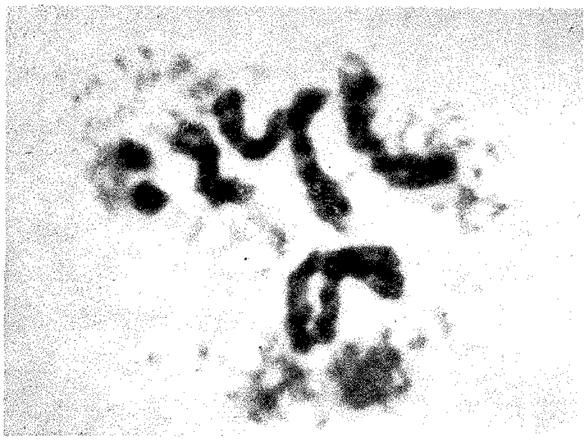

Fig. 1. Normal chromosomes of *Glossina pallidipes* from brain of puparial contents. Two large pairs, one medium and one small, are present. (× 2,500.)

puparia was unknown. The procedure of Itard[1] was followed, except that propionic acid replaced acetic acid wherever the latter had been used, staining being allowed to proceed overnight and the material mounted in 2 : 3 lactic acid : propionic acid.

Good results were obtained up to a month after fixation of the brains in propio-alcohol, a factor which could be useful when collections are made in remote areas.

Glossina pallidipes has four pairs of chromosomes: two long, one medium and one short (Fig. 1). All of the three larger chromosome pairs are metacentric, an interesting departure from the situation in *Glossina tachinoides* and *Glossina morsitans orientalis*, where one of the three larger pairs is said to be sub-acrocentric.

The average absolute lengths of the chromosomes are given in Table 1. The two larger chromosome pairs are treated together (described later). Table 1 also shows the relative lengths of the chromosomes, which provide a better basis for the comparison of chromosomes than do the absolute lengths. The relative length of a chromosome is given by the actual length expressed as a percentage of the total diploid chromosome length.

The small and medium pairs of chromosomes in *Glossina pallidipes* are easily recognizable by their size. The similar lengths of the two large pairs make it impossible to distinguish between them with certainty. One is usually longer than the other, but variation is such that one cannot be sure that the longer is always the same chromosome. It has not been possible to detect any constant morphological feature to aid in identification. The banding which shows up in occasional figures (see Figs. 1 and 2) might be of use in this way if it could be routinely shown up in preparations. The frequency distribution of the lengths of fifty-eight large chromosomes from eighteen figures derived from seven puparial contents is shown in Table 2.

Table 1. LENGTHS OF *G. pallidipes* CHROMOSOMES

	Chromosome:	small pair	medium pair	large pairs
Actual length (μ)	Mean (n)	1·68 (27)	5·72 (31)	7·80 (58)
	Standard error	0·1106	0·2189	0·3264
Relative length (%)	Mean (n)	3·7 (30)	12·3 (36)	16·9 (64)
	Standard error	0·2821	0·2607	0·2470

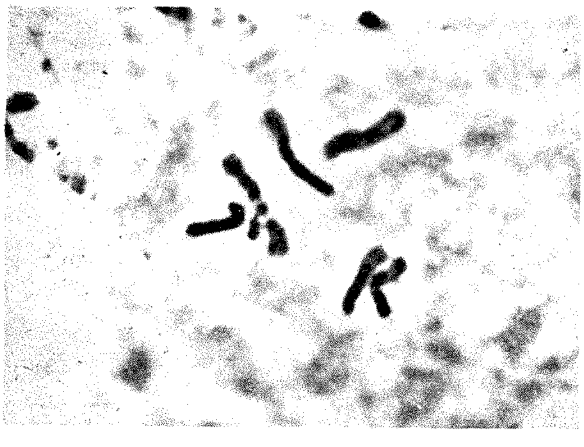

Fig. 2. Unusual chromosome complement from brain of puparial contents of *Glossina pallidipes*. Only three large chromosomes are normal, the fourth is clearly sub-acrocentric. Between the sub-acrocentric chromosome and the nearest large metacentric chromosome can be seen the single small chromosome; the other member of the pair is absent. (× 2,000.)

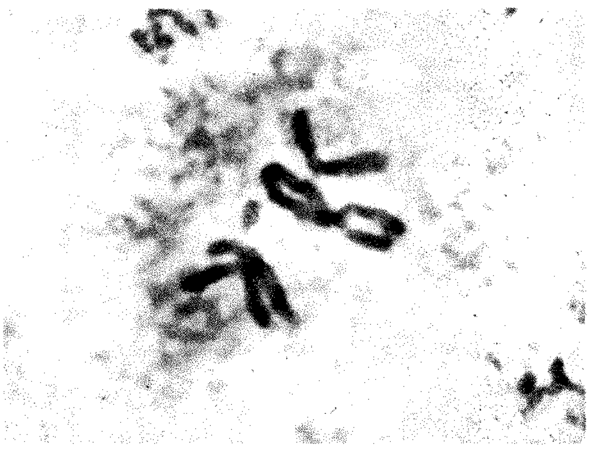

Fig. 3. Unusual chromosome complement from brain of puparial contents of *Glossina pallidipes*. Only one member of the small pair of chromosomes is present. One member of the medium pair is masked by the other which lay above it. (× 2,500.)

There is a hint of bimodality, which may be shown to be real if large numbers of chromosomes were measured. This was not undertaken because the results of such an exercise would not help in identifying the large chromosomes in any one figure, even if bimodality were established. The measurements of the two largest pairs of chromosomes have thus been lumped and the chromosomes treated as if of equal length. This seems to be the only way of dealing with these chromosomes at present.

Some variability seems to occur in the chromosomes of *Glossina pallidipes*. Two unusual chromosome complements are shown in Figs. 2 and 3. Each of these was seen in numerous figures and cannot be a result of some accident in preparation of the material. Fig. 2 shows a complement in which one member of the small chromosome pair is missing, and one member of a large pair is a sub-acrocentric chromosome. A similar situation was seen in another brain, except that both small chromosomes were in this case present. Although this could clearly be seen, no figure gave satisfactory photographs for illustration. In Fig. 3 is seen an otherwise normal complement where one member of the small chromosome pair is missing. (The apparent lack of a medium chromosome is a result of the screening of one member of the pair by the other lying above it.) Itard[1] mentions an instance (an abortive "pupa") in *Glossina morsitans orientalis* where an extra small chromosome was present. Three unusual chromosome complements in the comparatively small sample carefully investigated (many of the field-collected puparia were of unsuitable age; completely satisfactory preparations from twenty-five puparia, each showing a number of figures, comprised the actual sample size) indicate that considerable variability in chromosomal complement and structure might be found to exist in *Glossina pallidipes*.

Itard[1] has shown that there is a difference in chromosome number between *Glossina morsitans orientalis* ($2n = 10$) and *Glossina tachinoides* ($2n = 6$) which belong, respectively, to the "*morsitans*" and "*palpalis*" groups[2]. The present study has shown that the chromosome number ($2n = 8$) of *Glossina pallidipes* ("*morsitans*" group) differs from both. There are thus differences in chromosome number between species belonging to the same group as well as between species belonging to different groups. The work on these three species thus indicates that there might perhaps be found to be less correlation between chromosome morphology and the taxonomic entities comprising the tsetse-fly groups than one might have hoped. More data, however, are necessary before conclusions can be drawn.

Accumulation of Dry Matter by *Chrysanthemum morifolium* after Flower Removal

Sweet and Wareing[1] have recently discussed the role of plant growth in controlling the rate of photosynthesis by increasing the translocation of assimilates from the leaves. We have worked with *Chrysanthemum morifolium* grown as a flowering pot plant[2] in conditions in which the flowers became an important sink for assimilates. We have examined the effect of removing these sinks on the accumulation of dry matter and our results seem to illustrate a system in which the rate of accumulation of dry matter is not affected by the removal of an important sink.

Rooted cuttings of the cultivar 'Bright Golden Anne' were potted into John Innes No. 1 compost on May 18, 1967, and raised in a glasshouse under 8 h days at a minimum night temperature of 15·5° C. One week after potting, the growing point and young leaves were removed from all plants to induce lateral growth. After a further 2 weeks the lateral growths were reduced to three per plant and the axillary buds were removed from each lateral growth to leave a single terminal flower per branch.

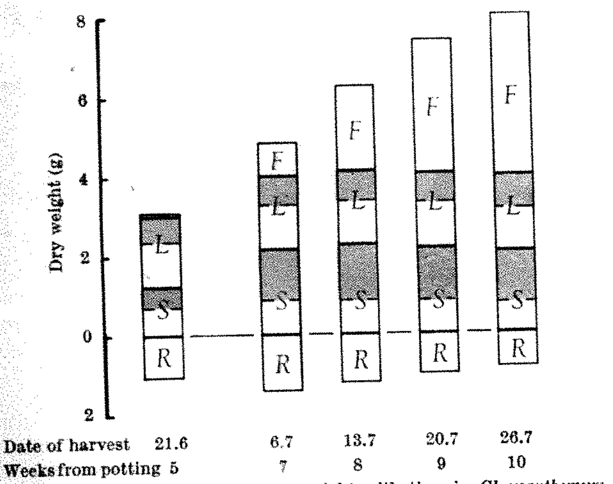

Fig. 1. The distribution of dry weight with time in *Chrysanthemum morifolium* cv 'Bright Golden Anne'. Means of five plants on each occasion. Shaded areas, branch; white areas, main axis. *F*, Flower; *L*, leaf; *S*, stem; *R*, root.

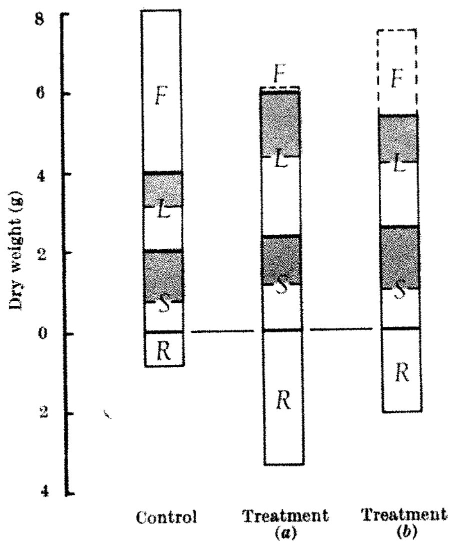

Fig. 2. The distribution of dry weight after flower removal in *Chrysanthemum morifolium* cv 'Bright Golden Anne'. Means of five plants. Control harvested July 26, 1967. Treatment (*a*): Flowers removed June 24, 1967, plants harvested July 27, 1967. Treatment (*b*): Flowers removed July 14, 1967, plants harvested July 27, 1967. Symbols as in Fig. 1. The dotted line encloses the weight of flower removed.

Five plants, chosen at random, were removed on each of five occasions (after 5, 7, 8, 9 and 10 weeks from potting up) and divided into leaf laminae, stems plus petioles, flowers, and roots. The leaves and stems were further subdivided into main axis and branch components. The fresh and dry weights of each of these fractions were measured together with stem length, and an assessment of flower development was made using the scale which we outlined earlier[2]. The data from these harvests are presented in Fig. 1 from which it is clear that as the terminal flowers developed they became almost the only site for the net accumulation of dry matter and the weight of the vegetative parts remained relatively constant. We also modified this pattern of accumulation by two treatments involving removal of flowers. In treatment (*a*) all three terminal flower buds were removed on June 24 when they were less than 15 mm in diameter (flower stages 2–3) and before they were the sole centres for the accumulation of dry matter. In treatment (*b*) terminal flowers were removed on July 14 when the flowers were expanding rapidly (flower stage 6–7) and when a pattern of diversion to flowers only was clearly established. It is worth noting that because all axillary buds had been removed there was no capacity for new aerial growth. Five plants were removed from each of these treatments on July 27 and divided as previously described. The data are presented in Fig. 2, together with the results obtained on July 26 from the plants with flowers.

These data show that if flowers were removed then an alternative existing sink assumed predominance and material was diverted in particular to the roots and to a lesser extent to the leaves. If the weights of flowers at the time of removal were added to the total weights of the flowerless plants at July 27, then the gross total of dry matter formed was similar in all cases. The leaves were almost fully expanded at the times when flowers were removed and at the end of the experiment the total leaf areas were similar in all three treatments.

The measurements of stem length in Table 1 show that the removal of the developing flower at stage 2 (treatment (*a*)) caused a cessation of stem extension although

Table 1. EFFECT OF FLOWER REMOVAL ON GROWTH OF THE LATERAL STEMS

Treatment	Harvest dates	Length (cm)	Weight (mg)	Wt./unit length (mg/cm)	Flower stage
With flowers	21.6.67	9·0	178	19·8	2·0

With flowers	20.7.67	16·2	429	26·5	8·0
With flowers	26.7.67	15·9	421	26·5	8·7
(*a*) Flowers removed June 24, 1967	27.7.67	11·0	404	37·8	—
(*b*) Flowers removed July 14, 1967	27.7.67	15·5	519	33·5	—

Means of three laterals per plant, five plants on each occasion.

the accumulation of dry matter continued and at the final harvest the dry weight of the lateral stems was similar to that of the controls with flowers. The weight of unit length of stem was therefore increased considerably. Thus extension growth was terminated by flower removal and did not seem to be affected by a continuing supply of dry matter. In the control plants, extension of lateral stems ceased when the flowers had reached flower stage 6 and the net accumulation of dry matter stopped at about the same time.

The evidence therefore suggests that when sinks are removed from the chrysanthemum without altering the area of the leaf surface (although the weight per leaf and possibly the thickness are changed), then there is no marked depression in the rate of accumulation per unit area of leaf surface and in the long term no great differences are observed in the total dry weight produced. Although short term changes may have occurred, the chief effect has been to direct materials to an alternative sink. A similar effect has been noted by Edelman[3] in the Jerusalem artichoke in which, in normal conditions, the growth of the aerial organs ceases and photosynthates are diverted to stem tubers. If these stem tubers are removed, then an alternative sink becomes predominant and the dry matter accumulates in and distends the fibrous roots. Thus the main change induced by the surgical removal of the principal sink has again been in the distribution pattern.

Although the total dry weights in Fig. 1 are similar, the total dry weight of plants with flowers was slightly less than the gross total for plants without flowers. This difference was probably the result of a combination of two factors. First, shading of the leaves by the opening flowers during the period from approximately July 13 to July 26 and, second, a reduction in the respiratory load of the treated plants because of the removal of flowers. This would give the maximum benefit to treatment (*b*) in which the weight of flowers removed exceeded 2 g.

In an earlier experiment, the rooted cuttings were potted into John Innes No. 1 compost on September 22, 1966. The cultural treatments were as described previously and the flowers were removed at flower stage 2–3 (November 17, 1966) when their contribution to total respiration was probably small. The plants were harvested after only 2 weeks of further growth (December 1) when the florets were just beginning to expand rapidly (flower stage 6) but before any appreciable shading of the leaf surface had occurred. In these conditions, the total dry matter produced by treated and untreated plants was the same after only a fortnight of further growth (Table 2). The distribution pattern had altered, however, and the roots had again become the most important sink for assimilates.

We conclude that growth in the chrysanthemum (in the restricted form we have studied) has been controlled by the rate of photosynthesis. The removal of the most important sink (flowers) permits the other sinks to control the distribution.

Table 2. DRY WEIGHTS (g) OF PLANT PARTS AT HARVEST

	Leaf	Stem	Root	Flower	Flower removed	Total
With flowers	1·69	1·77	0·77	1·02	—	5·24
Without flowers	2·04	1·83	1·26	—	0·16	5·29
Difference	0·36	0·06	0·49			

Means of five plants. Potted September 22, 1966. Flowers removed November 17, 1966. Harvest December 1, 1966.

ANTHROPOLOGY

Fossil Hominoid Vertebra from the Miocene of Uganda

THE Miocene site of Moroto II in Karamoja, Uganda, was first described by Bishop and Whyte in 1962 (ref. 1). The only primate specimens so far recorded from this site are dental and cranial remains that have been assigned to *Proconsul major*, Le Gros Clark and Leakey[2,3]. Among fragmentary specimens from Moroto II in the Uganda Museum, Kampala, eight can be shown to be part of the vertebral column of a chimpanzee-sized ape. Four of the fragments, although collected in different years, combine together to make an almost complete lumbar vertebra—the first recorded not only for the *Proconsul* group but for any dryopithecine. The specimens are: *U.M.P.*67.28—an almost complete middle lumbar vertebra; *U.M.P.*68.05—a badly eroded middle lumbar vertebral body; *U.M.P.* 68.06—a last thoracic vertebral body; *U.M.P.*68.07—the laminae and base of spine of a lumbar vertebra; and

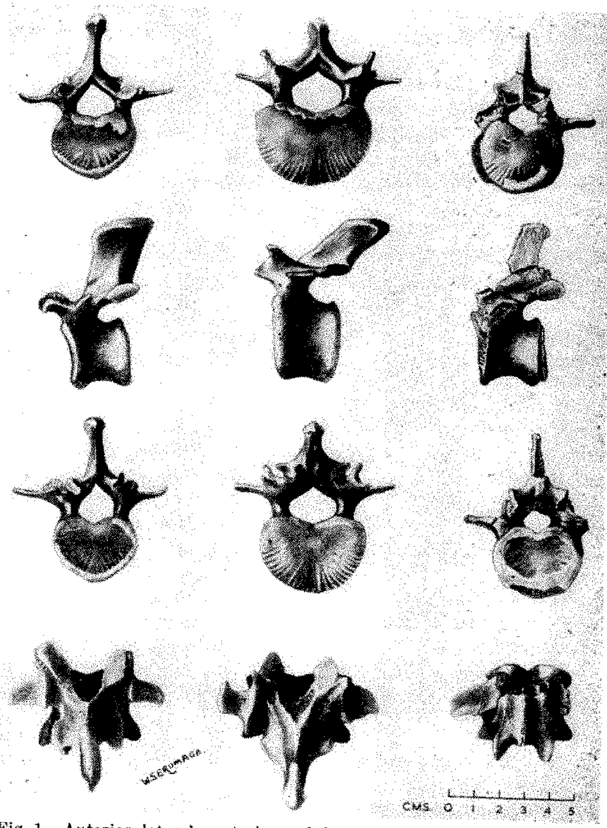

Fig. 1. Anterior, lateral, posterior and dorsal views (from above downwards) of first lumbar vertebrae of a chimpanzee (left) and a juvenile gorilla (middle) compared with the Moroto vertebra (right).

*U.M.P.*68.08—the laminae and base of spine of a thoracic vertebra.

The almost complete vertebra lacks the anterior articular processes, the right transverse process, and the tip and both anterior and posterior borders of the spine. The body is robust and presents reniform anterior and posterior surfaces, with the anterior surface being more nearly circular than the posterior. The posterior surface shows a well defined and fused ring epiphysis (as seen in *Homo* and the modern pongids but not in monkeys), but the anterior epiphysis has been mostly broken away to reveal the radiating rugae on the body proper. There is a slight ventral roughening for the longitudinal ligament. The body is distinctly "waisted", expanding anteriorly and posteriorly but not dorsally in the midline. This expansion accentuates the reniform outline of the anterior and posterior surfaces, narrows the vertebral foramen anteriorly and makes the posterior vertebral notch shallow dorso-ventrally. The pedicles are extremely thick and elongated antero-posteriorly, with the result that the posterior vertebral notch is shallow antero-posteriorly and the vertebral foramen further narrowed. The ventral part of a small anterior vertebral notch is evident on the left. The transverse process is triangular in section with a dorsal flattened surface, and springs from near the base of the pedicle. The posterior articular processes are short and nearly parallel. The articular facets are almost circular in outline and face ventro-laterally at an angle of about 60° to each other. They are gently convex transversely and almost totally overhang the posterior border of the body. The spine is long, slender and directed slightly posteriorly. A slight thickening at the dorsal extremity is taken to represent the base of the tubercle. Although both the anterior and posterior borders are eroded or missing, it is clear that the spine was a thin triangle in section, the apex anteriorly. There are two conspicuous pits at either side of the base of the spine at the anterior border of the laminae and two elliptical depressions on the neural surfaces of the laminae which represent the attachment of strong ligamenta flava. The anterior notch between the laminae is small and does not extend posteriorly to the extent seen in modern pongids. Measurements are given in Table 1.

The complete lumbar vertebra is of the same size as those of an adult male chimpanzee (*Pan troglodytes*). The only cranial remains of any primate from the site are those of *Dryopithecus* (*Proconsul*) *major*, which was the size of a large male chimpanzee, so it seems reasonable to assign these vertebral remains to the same species. In most important respects the lumbar vertebra resembles those of *Pan* and *Gorilla*, but possesses some hominid features. In the very narrow vertebral foramen, the extent and small size of the anterior laminar notch and the steepness of the articular surfaces, this specimen resembles the condition seen in *Homo* rather than in the pongids. In the long, thin spine and the thin transverse process, the Moroto vertebra resembles those of *Pan*. In the stoutness and position of the pedicles and in the detailed marking and positions of the pits for the ligamenta flava this vertebra is much more like those of *Gorilla*. There are therefore quite eclectic resemblances to modern hominoid vertebrae to be seen in the Moroto vertebra, but none of them would necessarily preclude *Dryopithecus* (*Proconsul*) *major* from being a direct ancestor of the genus *Gorilla*, a relationship which Simons and Pilbeam[4] support. Leakey[5], although not regarding the Moroto hominoid as *Dryopithecus* (*Proconsul*) *major*, nevertheless accepts the possibility of it being ancestral to *Gorilla*. It is hoped that a more detailed study will throw light on the varied resemblances of this vertebra.

Table 1. MEASUREMENTS (*U.M.P.*67.28)

	mm
Max. transverse diam. ant. surface of body	34·0
Max. dorso-ventral diam. ant. surface of body	29·0
Max. transverse diam. post. surface of body	37·0
Max. dorso-ventral diam. post. surface of body	27·0
Max. antero-posterior length of body	29·5
Total dorso-ventral diam. vertebra	64·0
Max. width vertebral foramen	11·0
Max. height vertebral canal	8·0

The other specimens are too fragmentary to add many data at this stage.

We thank the trustees and the curator, Mr C. Sekintu, of the Uganda Museum, and Dr W. W. Bishop for their kindness and assistance.

APPLIED SCIENCE

Wear of Carbon Fibre Reinforced Polymers in a High Vacuum Environment

THE friction and wear properties of carbon fibre reinforced polymers in dry conditions of sliding in air have recently been reported by Lancaster[1,2]. His findings, that the fibres reduced the wear rate and coefficient of friction of almost all the polymers studied, have promoted considerable interest in these materials. In addition, the resulting improvements in strength and stiffness properties suggest that they are attractive for use as self-lubricating components in aerospace engineering. The wear performance of a variety of these composites in a high vacuum environment has been investigated in this laboratory. It has been found that the addition of fibres can be effective in reducing the wear rate of the polymer in vacuum, but it is also evident that whereas in air rates of wear tend to decrease with increasing fibre content, in a vacuum high fibre concentration (40–50 per cent) is definitely deleterious to the wear performance of the composite.

Wear rates were determined by means of a pin and cylinder type wear rig. Hemispherically tipped cylindrical pins $\frac{1}{8}$ in. in diameter were machined from the polymer test specimens and loaded radially against a $\frac{3}{4}$ in. diameter stainless steel (*EN58BM*) cylinder, polished to 6 μ in. centre line average. This apparatus was enclosed in a bakable vacuum test chamber of 'Pyrex' glass and stainless steel construction, capable of being pumped to pressures in the region 10^{-9} to 10^{-8} torr. Vacuum processing was in accordance with high vacuum technique and contamination of surfaces was minimized by the use of oil-free pumping systems.

The wear rates obtained in vacuum for a number of different composites are given in the second column of Table 1. The carbon fibres in each composite were oriented randomly and are specified in weight percentage concentrations. All tests were conducted at the same sliding speed, 70 cm/s, and applied load, 120 g.

The extent to which the carbon fibre can reduce the specific wear rate of the polymer in vacuum is demonstrated in the case of acetal homopolymer where the reduction is approximately three orders of magnitude compared with the unfilled material. The wear rate for a polytetrafluoroethylene (PTFE)–glass fibre–molybdenum disulphide composite is also included in Table 1, because this is a self-lubricating material commonly used in vacuum

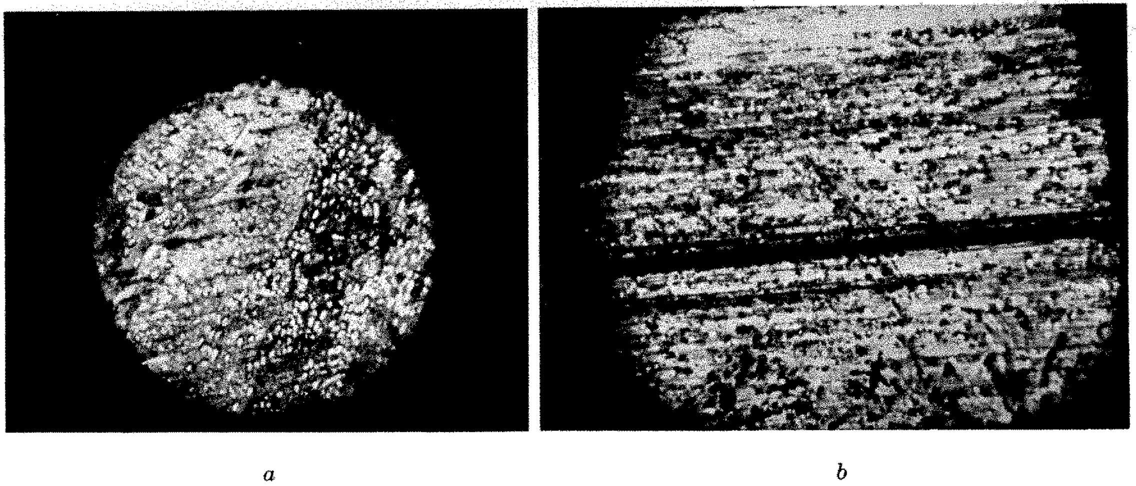

Fig. 1. Photomicrographs of the wear scars produced on riders of polyimide reinforced with 50 per cent by weight high modulus carbon fibres, sliding against *EN*58*BM* stainless steel (*a*) in air, (*b*) in vacuum of 10^{-8} torr. Load, 120 g; speed, 70 cm/s. (× 200.)

applications and therefore provides a convenient yardstick for comparison. Two of the carbon fibre composites have been found to exhibit greater wear resistance than this material.

Wear rates for the various composites were also determined in air. These results are presented in the third column of Table 1. The wear rates measured in air were usually substantially lower than for the same composites in vacuum. It is notable that for the lowest concentration of fibre used, that is, 15 per cent in acetal copolymer, there was virtually no difference in performance in the two environments, whereas the greatest differences were observed for the highest (45 per cent and 50 per cent) carbon fibre content materials. High fibre contents therefore tend to give a low wear rate in air but a high wear rate in vacuum. These findings are consistent with the established behaviour of carbons and graphites independently of the polymers. It is well known (see, for example, refs. 3 and 4) that carbons lose their lubricating ability in vacuum or dry atmospheres, becoming severely abrasive. It seems that at low concentrations any abrasive action attributed to the carbon fibres does not degrade the wear performance of the composite, and may even be beneficial in aiding the establishment of a thin, friction-reducing transfer film on the metallic surface. At high concentrations, however, the carbon abrasion becomes dominant in the wear mechanism with consequent degradation in the wear performance of the specimen.

Table 1. SPECIFIC WEAR RATES OF CARBON FIBRE FILLED POLYMERS AGAINST *EN*58*BM* STAINLESS STEEL IN VACUUM OF 10^{-8} TORR

Composite	Specific wear rate ($cm^3/cm/kg \times 10^{-10}$) Vacuum	Air
Acetal homopolymer + 25 per cent carbon fibre	0·06	0·03
Acetal copolymer + 15 per cent carbon fibre	0·13	0·14
Acetal copolymer + 45 per cent carbon fibre	0·58	0·025
PTFE + 25 per cent carbon fibre (Type 2)*	0·89	0·26
Nylon + 25 per cent carbon fibre	1·50	0·18
Polyimide + 50 per cent carbon fibre	230	0·01
PTFE + glass fibre + MoS_2	0·30	0·16
Acetal homopolymer (unfilled)	74	1·9

* Type 2, high strength fibres: ultimate tensile strength (UTS) $\simeq 410 \times 10^3$ lb. in.$^{-2}$; elastic modulus $\simeq 32 \times 10^6$ lb. in.$^{-2}$. Remainder, high modulus fibres: UTS $\simeq 280 \times 10^3$ lb. in.$^{-2}$; elastic modulus $\simeq 54 \times 10^6$ lb. in.$^{-2}$.

Table 2. INFLUENCE OF COUNTERFACE ON WEAR OF COMPOSITES IN AIR

	Specific wear rate ($cm^3/cm/kg \times 10^{-10}$) Stainless steel (*EN*58*BM*)	Mild steel (*BS*15)	Mild steel* (*BS*15)
Acetal copolymer + 15 per cent carbon fibre	0·14	2·4	0·9
Nylon + 25 per cent carbon fibre	0·18	0·9	2·0

*After Lancaster (personal communication).

Visual evidence supporting this conclusion is presented in Fig. 1, which shows photomicrographs of the scar areas produced on specimen pins of polyimide + 50 per cent carbon fibre after sliding in air and vacuum. The nature of the wear surface produced is clearly different in the two environments. Whereas the in-air sliding has resulted in a smooth, polished surface, in which the ends of the carbon fibres are themselves smooth and clearly defined, the scar produced in vacuum is severely scored and shows evidence of carbon "dusting".

There is an apparent disagreement of about one order of magnitude between the in-air wear rates presented here and those reported previously[1]. But it should be noted that different substrates were employed in the two investigations—stainless steel in the former and mild steel in the latter. On re-determining the results for acetal copolymer and nylon composites against mild steel (*BS*15) it was confirmed that these materials exhibited significantly greater rates of wear against mild steel than against stainless steel. These results are presented in Table 2, in which the values obtained by Lancaster (private communication) using a mild steel counterface are also given for comparison.

It is clear that the counterface material can play an important part in determining the wear of these composites in air. The wear mechanism in vacuum appears to involve the transfer of composite material to the metal surface. Inspection of the cylinder specimens after a sliding test showed that in most cases a thin visible track of transferred material had been formed and in the case of polyimide, containing 50 per cent carbon fibre, gross transfer was observed.

This work was carried out as part of a programme supported by the Ministry of Technology. We thank Dr J. K. Lancaster of the Royal Aircraft Establishment, Farnborough, for his co-operation in supplying the range of sample materials studied and general interest in the work. The materials discussed are the subject of patent application No. 33570/66 by R. C. Fullerton-Batten, J. K. Lancaster, L. N. Phillips and G. Wood, "Carbon Fibre-Resin Composite Bearing Materials".

BOOK REVIEWS

AGE OF FACTS

American Science in the Age of Jackson

By George H Daniels Pp viii + 282 (New York and London Columbia University Press, 1968) 72*s*

The aim of this original book is to characterize a particular aspect of a specific society the attitude towards science in the United States of America between 1815 and 1845 Mr Daniels is not interested in scientific achievement and this is just as well, for, as he is aware, and as the men of his period lamented, there were few notable contributions to science from early nineteenth century America. The heroic age of colonial science represented by Benjamin Franklin, the two John Winthrops, or David Rittenhouse, all Fellows of the Royal Society, had ended with the emergence of the new American nation; only Asa Gray and James Dwight Dana, both still young men in 1845, were to become FRS (in 1873 and 1884, respectively) among the many men whose ideas and work are described here

Admirably, Mr Daniels sees his subject in perspective and neither makes nor wishes to make great claims for the men whose ideas he analyses The active scientists were a serious and professional group, nearly all American born, nearly all associated with education—most college graduates, and the majority employed in the growing number of colleges and universities as teachers of science, though many lacked formal training By analysing journal articles Mr Daniels concludes that American science in this period was, on the whole, specialized, not specifically utilitarian, and by no means largely devoted to natural history

A considerable part of this book is devoted to an examination of published views on scientific method, from which it appears that American philosophers and theologians wrote much on the subject Mr Daniels finds the preferred scientific method of this period an extreme "Baconianism", a reverence for what was taken to be Bacon's (and Newton's) exaltation of fact at the expense of theory, a tendency to decry hypothesis as fanciful and to demand the collection of ever more facts To some extent this was justified Darwin and Hooker deplored the free speculation of *The Vestiges of the Natural History of Creation* every bit as much as Asa Gray Many of the subjects investigated by American scientists—the theory of storms, the aurora borealis, the geological structure of their continent—could hardly proceed without more facts, and the first theories were indeed wildly speculative Further, fact was safer than theory, which often led to heartbreaking controversy And, as Bacon himself had recognized, factual science is more democratic than theoretical science, because it is more readily understood by all One very obvious reason for this excessive empiricism was American intellectuals' fear of European "materialism", ironically they saw Baconianism as a conservative force, where European conservatives like De Maistre saw it as an agent of revolution Another reason was the peculiarly theological tone of the American intellectual scene American colleges and universities were not secular, on the contrary, they were highly sectarian and, as college teachers, scientists were expected to accept the tenets of the sect associated with their institutions A scientist unconcerned with religion would find employment difficult All geological speculation was therefore particularly suspect; it is no wonder that Darwin created such a storm in the New World

By his choice of subject Mr Daniels has avoided many of the pitfalls usual in a national history of science Unfortunately he has neglected European science of the period excessively So he does not find it odd that, in 1819, a Boston physician deplored the "overthrow" of Lavoisier's "system" and hence he misinterprets the complaint of a professional chemist (Robert Hare, not a great theoretician) that non-chemists could not understand his work. Both these remarks are signs of what Mr Daniels instances elsewhere, a growing degree of professionalization. That Benjamin Rush was praised for expounding mechanistic physiology in 1768 whereas a physician named Emmet was censured for doing the same thing in 1822 merely reflects events in Europe the decline in popularity of Haller's views and the dominance of the French school which followed the doctrines of Bichat, whose definition of "life" is given here as original with Elisha Bartlett in 1844 The works of Bichat and Richerand were printed in Philadelphia in this period, and were widely popular Indeed, in view of the fact that European travel and study were still uncommon, the concepts of American scientists reflect those of the main stream of European science remarkably well That writers on science were unaware of this is not surprising, nor that they were less well prepared than the scientists for the tremendous growth of science in America after 1845 It is to be hoped that Mr Daniels will analyse the later period in the same way as he has here analysed the earlier one For he has illuminated many interesting aspects of the American scientific scene

CALCIUM AND REPRODUCTION

Calcium in Reproductive Physiology

A Comparative Study of Vertebrates By K Simkiss (Modern Biological Studies.) Pp xiv + 264 + 9 plates (London Chapman and Hall, Ltd , New York Reinhold Publishing Corporation, 1967) 60*s* net

Dr Simkiss's capability as a reviewer of the literature is well illustrated in his new book on calcium regulation throughout the vertebrates Whereas in his previous articles in *Biological Abstracts* only specific topics of the subject were touched on, in the present book the entire scope of contemporary thinking on the hormonal regulation of calcium balance has been treated The author has done himself an injustice by entitling the book *Reproductive Physiology*, thus implying that it deals solely with the role of calcium ions in the reproductive process In fact, the content is much greater and covers most aspects of the controlling mechanisms of calcium levels in animals, as well as a more specialized consideration of excess calcium demand during the reproductive period

The first part of the book is devoted mainly to the general mechanisms of calcium regulation in different classes of vertebrates and deals with the role of calcified tissues, the digestive system including the liver, and the kidney in the adjustment of calcium balance and serum calcium concentrations The effects of the thyroid–parathyroid complex, the sex steroids and vitamin D on these organs are also discussed The author has rightly emphasized the non-infallibility of some of the experimental approaches in these studies, particularly those which attempt to extrapolate results from short-term measurements into long-term balance effects Although there has been no attempt to describe the experimental techniques in detail, the principles behind them have been adequately treated and their usefulness evaluated

The second part of the book is a survey of the regulation of calcium during ovulation, egg-shell formation, pregnancy and embryonic growth, as the case may be, in different classes of tetrapods It terminates with a stimulating chapter of conclusions and speculations As the author has admitted, this book is theoretical rather than applied and caters primarily for zoologists and comparative physiologists Nevertheless, it is very informative owing to the inclusion of large numbers of tables and figures, so that for the applied physiologist and veterinary and medical scientists who are interested in calcium metabolism it serves as a useful handbook On the whole, the literature covered is quite complete It illustrates the amazing paucity of information on the regulation of calcium in vertebrates other than the tetrapods With the recent discovery of (thyro)-calcitonin and its identity as the hormone secreted by the ultimobranchial bodies, the subject of hormonal regulation of calcium balance is bound to attract more and more attention. This book is a timely review of the past literature and stands out as a milestone to mark the beginning of perhaps a new era.

PHENOLS OXIDIZED

Oxidative Coupling of Phenols

(Organic Substances of Natural Origin a Series of Monographs, Vol. 1) By W. I Taylor and A R Battersby Pp. xiv+387 (London Edward Arnold (Publishers), Ltd, New York· Marcel Dekker, Inc, 1967) 260*s* net.

Phenols and phenol ethers represent a large proportion of the benzenoid-aromatic compounds which are of such widespread occurrence in nature Many of the more complex compounds, for example, alkaloids, tannins, lignins, and many quinonoid pigments are clearly the result of the oxidative coupling of two or more phenolic nuclei, and so much work on this subject has been done in the past few years that the time is ripe for the publication of a monograph on the subject.

It may be said straight away that the present monograph is extremely good It consists of a number of reviews on the most important aspects of the oxidative coupling of phenols written and edited by internationally recognized experts Each chapter is self-contained and there is surprisingly little overlap or duplication between one chapter and another. The text is profusely illustrated with beautifully printed structural formulae.

The first chapter (ninety-four pages, 424 references) is by H Musso and deals concisely with the general problem of phenol coupling in terms of mechanism, formation of C–C and C–O aromatic bonds, and so on. A particularly valuable feature is the comprehensive table of products formed by phenols (mostly "unnatural" ones) when oxidized by various reagents There is also a table of phenoxyls investigated by electron spin resonance methods The second chapter (twenty-three pages, sixty-six references) by A I Scott describes "Some Natural Products Derived by Phenol Oxidation" and gives a glimpse of the variety of naturally occurring phenolic products It whets the appetite for the specialized chapters which follow In the third chapter (fifty-seven pages, 134 references), A R Battersby discusses "Phenol Oxidations in the Alkaloid Field". Since the original suggestions on the possible biogenesis of morphine and other alkaloids by Robinson in 1931, it has been shown that over 200 of the more than 2,000 known alkaloids can be accommodated within the framework of the oxidative coupling of phenols For many alkaloids the detailed pathways of biosynthesis have been unravelled by feeding labelled intermediates to plants as well as by carrying out *in vitro* experiments In the fourth chapter (thirty-five pages, 105 references), entitled "Biochemical Aspects of Oxidative Coupling of Phenols", B R Brown summarizes our present, all too scanty knowledge of the enzymes which catalyse phenol-coupling The fifth chapter (thirty-eight pages, fifty-seven references), by D. W. Cameron and Lord Todd, gives a fascinating account of the aphin pigments The sixth chapter (seventy-nine pages, 277 references), by J M Harkin, and the seventh chapter (thirty-six pages, sixty-three references), by K Weinges and R Spanig, deal respectively with the industrially important, highly irregular polymer known as lignin and with "Lignans and Cyclolignans", which are essentially dimeric derivatives of propenylphenols

All chemists and biochemists interested in phenols and in phenolic natural products should read this monograph It is therefore most unfortunate that the price puts it beyond the range of all but a few individuals and the wealthier libraries

J. F W McOmie

VIRUSES IN THE LABORATORY

Virological Procedures

By J Mitchell Hoskins. Pp xiv+358 (London· Butterworth and Co (Publishers), Ltd, 1967) 70*s*

This book has been written for those concerned with the laboratory diagnosis of virus infections of man, with particular reference to the problems existing in the British Isles. The author considers that a virus diagnostic laboratory should have certain essential services available, and that these services should be used in different ways to meet the particular requirements involved in diagnosing infections with different viruses. Following this logical approach, the book is divided into five sections The first and largest deals with basic laboratory facilities ranging from considerations of the design of suitable accommodation, through technical points concerning equipment, washing and sterilization procedures, to more detailed accounts of the uses of experimental animals embryonated eggs and tissue cultures in virology The preparation of monkey kidney cell cultures is described as an instance of primary cell cultures, and the handling o HeLa cells is used to illustrate the uses of cell lines The treatment of diploid cell cultures and of organ culture methods is less detailed, although useful in the context o the book The information on the uses of laboratory animals and of embryonated eggs is presented clearly with appropriate illustrations

The second section is concerned with the isolation o viruses, starting with the collection of clinical materia and describing the various ways in which virus isolation may be attempted Virus strains successfully isolated must then be identified, and the third section deals with this problem, indicating some of the clues which may assist the virologist in his task, and concluding with methods for the identification of specific viruses

Some virus infections are diagnosed on the basis o serological evidence, and the fourth section is concerned with serological procedures Recommended methods fo preparing and standardizing diagnostic antigens an reference antisera are given, with details of the ways i which complement fixation, haemagglutination-inhibition neutralization and other serological tests are carried out The fifth section suggests the methods of choice fo investigating different groups of viruses This material i presented in the form of tables summarizing criteri which are considered useful in diagnosing infections du to particular groups of viruses, for example the picorna viruses and the myxoviruses This whole section is shor and while tabulation has many advantages the presence of forty-nine footnotes to the table on myxoviruses is no an attractive feature The book concludes with appendixe giving formulae of commonly used media, buffers an stains, and tables of logarithms and antilogarithms

This fairly compact volume contains much that will b of great practical value in a virological laboratory Th author has been selective, and not everyone will agre with his selection on points of detail A major criticism is the complete absence of references to original sources, apart from a list of twelve books recommended for supplementary reading J S. PORTERFIELD

BIOLOGY OF DREAMING

The Biology of Dreaming

(A Monograph in the Bannerstone Division of American Lectures in Living Chemistry) By Ernest Hartmann Pp xiii+206 (Springfield, Illinois Charles C. Thomas, Publisher, 1967) $9 75

SLEEPING and dreaming are of increasing interest to a range of research workers from widely differing basic backgrounds The information explosion of the past decade, due to energetic sleep research, has led to a situation where research is now reported in almost every journal at some time or another It can therefore be very difficult at times to find what is being thought currently about some aspects of this research Many sleep researchers are aware of this difficulty and have produced reviews, usually contained within suitable journals or more massive books

Dr Hartmann has taken on the task of describing present ideas on the biological, clinical and some psychological aspects of the problem of dreaming

He describes the basis for the experimental studies of sleep—although his illustrations in this section have not come out well It is also most unfortunate that after pointing out—admirably—that the neurophysiological state in which most dreaming has been found has already twenty-two names, he adds his own—the "D or dreaming state" The fact that he goes to pains to review at various points the data that dreams have been collected from the other type of sleep, now christened the "S state", emphasizes the semantic difficulty. Surely it is time we agreed on universal terminology

After a short but comprehensive account of the "dream deprivation" experiments and discussion of the demand for the "D state", the author gives a very neutral account of the controversies of the possible chemical basis for this state. There are very full accounts of the association of dreaming with mental illness despite the apparent gaps and conflicts in this area Association of the "D state" with physical illness is also interesting and I enjoyed his discussion of a possible connexion between the "D state" and psychosomatic illness, although our ignorance in this area is made apparent

The biological importance and function of the "D state" are dealt with without bias at the expense of over-inclusion at times

Obviously in this book there are instances where the current knowledge has outstripped the ideas present when the book was written, but these examples are minor

I enjoyed the book and despite its short length and very comprehensive data did not get the feeling of compression The bibliography is good

It is, however, an expensive volume, much of which will be dated rapidly I would see it as a good review which, made available by libraries, will carry its ideas to a wide range of people who otherwise might find difficulty in finding this material in the journals J I EVANS

ECONOMIC ANTHROPOLOGY

Themes in Economic Anthropology

Edited by Raymond Firth Pp x+292 (London Tavistock Publications, Ltd , 1967) 45*s* net

CONTEMPORARY economic theory is becoming increasingly divorced from reality and its arguments have assumed largely the character of futile intellectual *jeux d'esprit.* In so far as this volume is representative for the prevailing trend in economic anthropology—which it ought to be, considering that it is based on the collective wisdom of two scores of anthropologists assembled in conference in 1965—it seems that many economic anthropologists are well on their way towards adopting the most deplorable features of contemporary economics—choice of deliberately abstruse aspects of their subjects and their obscurantist treatment

The language of some of the essays in this book is admittedly still that of Marshall, Keynes and Malinowski, but others are dominated by the economic terminology invented for the purpose of deterring the layman from taking an interest That the participants of the conference, while at pains to familiarize themselves with the teachings of sophisticated contemporary economists, missed out their elementary lessons seems to be indicated by the fact that none of those who pooled their resources at the conference corrected Mary Douglas when she attributed to Adam Smith a frequently quoted remark by John Stuart Mill about the difficulties of barter between a tailor and a baker

Disregarding that minor error, Mary Douglas's essay on "Primitive Rationing A Study in Controlled Exchanges" is a contribution of outstanding interest But in spite of being an eminently lucid presentation of a subject of essentially practical interest, it must be classed among the intellectual *jeux d'esprit* For the author uses her remarkable erudition, incisive analysis and clarity of exposition for a *tour de force* to prove an utterly absurd thesis—that primitive moneys serve the purpose of rationing She failed to produce a single valid argument in support of her thesis But the superb skill with which she presented her basically false case compels admiration, mingled as it is with regret for the waste of such a superb display of scholarship in the service of such an undeserving case

Nothing could indicate more clearly the possibility of defending a wrong thesis in an impressive and convincing way than the fact that Mrs Douglas managed to convert such a formidable scholar as Raymond Firth, at any rate to the extent that, instead of rejecting her contention out of hand, he suggested in his opening essay that the analogy of primitive moneys to ration coupons offered "an intriguing set of criteria for discussion" (page 18) Had Professor Firth examined closely enough the factual evidence provided by Mrs Douglas I am sure he would have discovered that her ethnological instances are either perplexingly irrelevant or they prove exactly the opposite of what she seeks to prove.

Rationing is a system to ensure egalitarian distribution, while the evidence offered by Mrs Douglas conclusively reaffirms the generally known fact that the operation of primitive monetary systems results in increasingly unequal distribution. Such effect is inherent in these systems. This is certainly the case of the system on which she writes on the basis of first-hand knowledge, the use of raffia cloth units by the Lele In the course of her field research in that community, embodied in her excellent monograph *The Lele of Kasai*, she found that most raffia cloth—which could be produced by anyone—tended to accumulate in the hands of a small number of rich old men I could quote scores of instances of moneys operating in primitive communities that produced a similar effect It puzzles me beyond words how a highly intelligent anthropologist like Mary Douglas can possibly imagine that such a system makes for egalitarianism And since it does exactly the opposite, how can it be called rationing ?

Mrs Douglas stated that among the Lele every man could issue his own ration coupon to himself I failed to discover in her essay the strange process of reasoning by which she succeeded in convincing herself that virtually unlimited production of ration coupons "no more makes nonsense of the rationing analogy than it makes nonsense to speak of money when the unit of currency is freely produced and marketed" (page 131). I agree that the free production of the wampum and tobacco currencies by North Americans during the early colonial period does not make nonsense of their description as moneys, even though these currencies did reduce themselves to nonsense eventually as a result of their extreme depreciation. After all, bad money is nonetheless money for being bad. But it is unmitigated nonsense to label as rationing a system under which everybody is in a position to increase the number of his coupons at will. Such a system is not rationing, it is the very negation of rationing. Unlike free money, it would not merely reduce itself to nonsense through its misuse over a period—it would be logically, necessarily and inevitably nonsense from the very outset because it conflicts with the basic principles of rationing.

Mrs Douglas emphatically rejects the idea that raffia cloth performs monetary functions among the Lele. In my *Primitive Money* (revised edition, page 434), I tried to prove on her own evidence that it does play a limited part as a medium of exchange. However, whether raffia cloth is money is largely a matter of definition and there is room for two opinions about it. But no conceivable definition of rationing could possibly fit to the part played by raffia cloth.

When she gets away from her fixed idea Mrs Douglas can and does make valuable contributions to the subject of money. "Money in the international economy" she says, "is very like money in the primitive economy where no sovereign authority is in control" (page 139). This and some other shrewd observations do indeed offer a basis for stimulating discussion. They make me deplore it all the more that she has not turned her wide knowledge of primitive moneys and her original analytical mind to worthier use than her attempt to prove the unprovable.

The other essays in the volume include an introductory essay on "Themes in Economic Anthropology", by Raymond Firth, "One Economist's View of the Relationship between Economics and Anthropology", by Leonard Joy, "Economic Anthropology: One Anthropologist's View", by Ronald Frankenberg, "Economic Analysis and Economic Man", by Percy S. Cohen, "Economic Spheres in Darfur", by Fredrick Barth, with an essay commenting on it by Leonard Joy, "The Structure of Decision-Making among Indians of Colombia", by Sutti Ortiz, "Productive Efficiency and Customary Systems of Rewards in Rural India", by Scarlett Epstein, and "Traditional Groups and New Economic Opportunities in Rural Yugoslavia", by Lorraine Baric. Between them these essays cover a very wide sphere. It is a pity that between them they devote relatively little space to the task that could reasonably be expected to receive the utmost attention of present-day anthropologists—investigation of the problem arising from the sudden change from primitive to modern economy.

As a result of the violently sudden contact between backward and advanced communities during and since the war in various parts of Africa, Asia and Oceania, changes which usually occur very gradually have occurred very suddenly. Modern money, modern systems of production and modern market economy have been forced on backward communities in a matter of years, before they have become ready for such changes. The modern institutions are being applied, therefore, by communities whose minds are still primitive. This striking anomaly has given rise to interesting situations which ought to be investigated very thoroughly. They have been investigated in a number of communities by individual field workers during the past ten years or so. There have appeared several very valuable monographs dealing with the sudden transition from primitive to modern economy in individual communities. What is needed is an adequate summing up of their findings.

Admittedly, there are occasional references in this volume to such problems, but I have looked in vain for a systematic analysis of the evidence produced by field research workers. Is this because economic anthropology, like economic theory, has come to make it a point of honour to keep aloof from realities? Some of the contributors deem it more important to try to prove that Karl Marx was right than to find an answer to the interesting problems of the transition period of our days. All in all, although this volume contains much that is valuable and interesting, it has failed to fill the most important gap that exists in the literature on economic anthropology.

PAUL EINZIG

OBITUARIES

Professor J. D. Boyd

PROFESSOR JAMES DIXON BOYD died in Cambridge, after a long illness, on February 7, 1968. Born in the United States of America, he was taken to Northern Ireland at an early age and educated at the Royal Belfast Academical Institution and Queen's University, Belfast. His undergraduate career was a brilliant one, and he could obviously have made a niche for himself in any branch of medicine. He was, in fact, attracted to work in the department of anatomy at Belfast, and became one of the brightest stars assembled in that department by Professor Thomas Walmsley. After a Rockefeller fellowship, he went to Cambridge in 1935, where he became a university lecturer and Fellow of Clare College. By this time he had already acquired what was to be his principal interest, and on his appointment at the extremely early age of 31 to the chair of anatomy at the London Hospital Medical College, he had begun the collection of sectioned human embryos, second only to that of the Carnegie Institution, to which he was to add continuously during his period in London, and after his appointment to the chair of anatomy in Cambridge in 1951. His textbook on human development, known familiarly to generations of students as "Hamilton, Boyd and Mossman", has become a standard text and will long survive to mark both the depth of his scholarship and the long and fruitful collaboration he enjoyed with Professor W. J. Hamilton.

Although Dixon Boyd was an excellent administrator and one of the best and most enthusiastic of lecturers, his friends will remember him firstly as a microscopist, because on entering his room it was characteristic to see him bent over a microscopic preparation from which he would turn with his cheerful smile. He made a large number of contributions to the study of embryology, clearing up a wide range of problems relating to structures such as the carotid body, the pharyngeal pouches and the ganglia of the sympathetic nervous system. The subject in which he took most interest was the placenta and its formation. He quickly realized the potentiality of the electron microscope in studying this structure and made valuable discoveries as to its contents.

In some respects Dixon Boyd seemed to belong to an age earlier than the present, for he never allowed his own specific research interests to dominate his position as head of a department. He was one of the best-read men of his time, both within and outside his subject. His knowledge of the anatomical literature was so extensive that he was often consulted by experts, who went away inevitably with something new they had gleaned from his rich store. During the past few years when his health was sadly failing, he was engaged with his old friend and colleague, W. J. Hamilton, in the preparation of what is clearly designed to be a classic monograph on the placenta. Those who knew Dixon Boyd well will mourn the fact that he did not live to see its publication, but they will also know that, by his standards, to complete an important piece of scientific work was enough, praise from others for what he had done with his whole heart and mind was ever supererogatory.

DAVID WOOLLAM

University News . London

Mr H. J. Godwin, reader in pure mathematics at the University College of Swansea, has been appointed to the chair of statistics and computer science tenable at Royal Holloway College, and Professor A A Walters, professor and head of the Department of Econometrics and Social Statistics in the University of Birmingham, has been appointed to the Cassel chair of economics with special reference to money and banking tenable at the London School of Economics and Political Science The title of professor of immunology has been conferred on Dr I M Roitt, in respect of his post at the Middlesex Hospital Medical School

Appointments

Captain W E Morris has been appointed director of Royal Naval Aircraft and Helicopter Development in the Ministry of Technology, in succession to Mr L H. G Sterne

Dr M Shafqat H Siddiqi, chairman of the Pakistan Council of Scientific and Industrial Research, has been appointed the first overseas member of the Tropical Products Institute Advisory Committee

Announcements

The Council of the Royal Society of Edinburgh has awarded the Keith Prize for the period 1965–67 to Dr A J Haddow, senior lecturer in epidemiology in the University of Glasgow, for his paper "The Natural History of Yellow Fever in Africa" published in the *Proceedings* of the society during the period of the award

The Center for Theoretical Studies of the University of Miami has announced the establishment of the J Robert Oppenheimer Memorial Prize for significant contributions to the fields of theoretical physics, chemistry, biology, mathematics and the philosophy of science The prize, which consists of a gold medal, a citation and a cash award, is to be a tribute to the late Professor Oppenheimer, who, as a member of the Scientific Council, was instrumental in the founding of the centre Further information concerning this prize can be obtained from the Scientific Council, Center for Theoretical Studies, University of Miami, PO Box 9055, Coral Gables, Florida 33124

Meetings

Vacuum Congress, April 17–19, Manchester (The Secretary, Joint British Committee for Vacuum Science and Technology 47 Belgrave Square, London SW1)

Physics of Thin Films, April 22–24, Southampton (The Meetings Officer, The Institute of Physics and The Physical Society, 47 Belgrave Square, London SW1)

Annual Frequency Control Symposium, April 22–24, Atlantic City, New Jersey (Director, Electronic Components Laboratory, US Army Electronics Command, Fort Monmouth, New Jersey 07703)

The Scanning Electron Microscope—The Instrument and Its Applications, April 30–May 1, IIT Research Institute, Chicago (Dr Om Johane, IIT Research Institute, 10 West 35th Street, Chicago, Illinois 60616).

Time-dependent Effects in Polymeric Systems, May 10–11, University of Bradford (The Registrar, University of Bradford, Bradford 7)

Myeloproliferative Disorders of Animals and Man, May 20–23, Richland, Washington (Dr W J Clarke, Symposium on Myeloproliferative Disorders of Animals and Man, P O Box 999, Richland, Washington 99352)

CORRESPONDENCE

Geology in British Universities

Sir,—If geology is taken to mean the science of the Earth, then most university geology departments in Britain do not teach it Instead they offer a range of semi-independent, specialized courses within the field, from which the student is expected to construct his own view of the Earth The main reason seems to be repeated subject segmentation resulting from an accelerating increase in published data Departments at time of formation have been traditionally divided into branches or subject segments, with one teacher for each. Examples are palaeontology, stratigraphy and mineralogy (Fig 1). As data accumulate it eventually becomes clear that a segment will have to split, the original teacher taking one part and a new teacher the other For example, palaeontology might split into macro- and micro-palaeontology. The process can continue indefinitely

The system has three defects First, each subject segment is usually, though not always, separated from its neighbours by a subject gap—or even a crevasse In order to bridge this, those responsible for adjacent segments would need to be familiar with the topics covered by the other, and both would need to agree on a method of presenting the relationship. Such co-operation is rarely successful and is usually not attempted

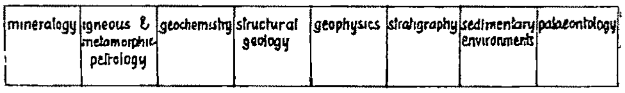

Fig 1 Example of the traditional segmentation of geology

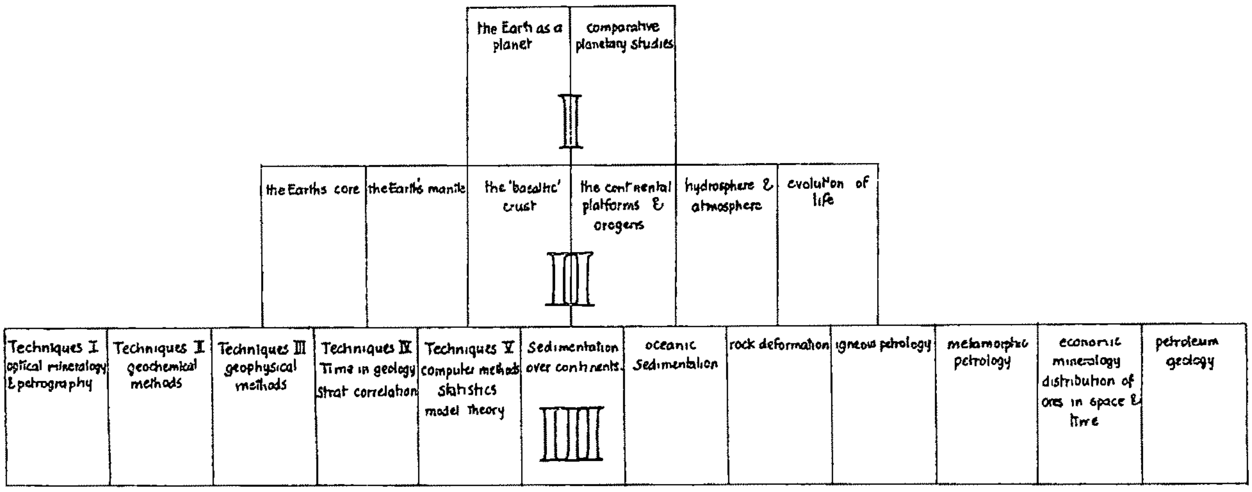
The second defect is that the simple segment structure tends to be self-perpetuating For most departmental heads the temptation to split an already existing segment rather than to create an entirely new one seems to be irresistible The effect on departmental research, necessarily closely related to segment structure, is obvious. Hence, developments during the past fifteen years, and particularly since the IGY in 1957–58, which have altered the very structure of the subject, are relatively neglected Geology as now usually taught is largely confined to the study of the exposed portions of the continental rifts This was inevitable in the past when knowledge of the Earth was gained from direct examination of its land surface Then, the only known way to link observations was to place them either in time sequence, or in descriptive groups (for example, minerals) But it is now becoming increasingly clear that at any given time events in the crust are closely connected both to one another, and to those in the upper mantle and probably also the core. They cannot any longer be treated in isolation as if they were parts of a series of independent Markov chains (for example, local stratigraphic columns).

The third and perhaps most serious defect of the present system is that virtually no research and little teaching is directed towards synthesis of geological information at any level above that of the segment Even within segments the historico-descriptive approach is commonly regarded as adequate The result is a rising mountain of undigested data Hence the necessity for repeated segment splitting and increasing specialization The necessity is largely illusory, the real need is for condensation of data into working hypotheses with a high degree of independence in space and time The fallibility of such hypotheses is recognized, but it does not destroy their central importance to the development of the subject Without them the recitation of geological history, with ever increasing precision, becomes an end in itself

Two excuses are usually advanced for the lack of synthesis in geology The first is the difficulty of dealing with the huge volume of data and the consequent danger of



the Earth as a planet
comparative planetary studies

III

Fig 2 Suggested three-tier hierarchy of subject segments Subjects shown are merely examples The number of tiers is variable, but two is a minimum

superficiality. The second is the lack of suitable people to do the work However, the need is not for synthesis in the encyclopaedic style of Suess[1] or Gignoux[2], but rather the use of codified data to derive such things as natural classifications of rocks and to define sedimentary, metamorphic, geochemical and tectonic crustal regions The construction of a nested hierarchy of simple quantitative models ultimately embracing the whole Earth can then follow. A similar approach has been suggested by Kosygin and Voronin[3] The contention of superficiality also overlooks the fact that the nature of problems changes with the scale of investigation (cf Haggett *et al*[4]) Thus, the petrographer working with a microscope does not dismiss field studies as superficial even though they are carried out on a scale at least five orders of magnitude greater

The lack of workers experienced in synthesis is certainly real However, there are probably more frustrated synthesists in British geology departments than might be suspected from listed research topics The one certain way to utilize them and to generate new interest, and hence research, in synthesis is to create a demand for it

As an alternative to the existing organizational structure in geology a three-tier hierarchical scheme is proposed (Fig 2) in which scale plays a key part and teaching is process oriented rather than descriptive The chief advantage of this scheme over the traditional one (Fig 1) is that the relationship between subject segments in any tier is dealt with by teachers in the next higher one—without, incidentally, the need for detailed collaboration of teachers either within or between tiers Such a scheme would provide an effective antidote to the cancer of specialization. It also puts much greater emphasis on the rapidly growing areas of the subject, which is essential if universities are to equip students for a working life during which the total amount of geological knowledge may be expected to increase sixteen-fold

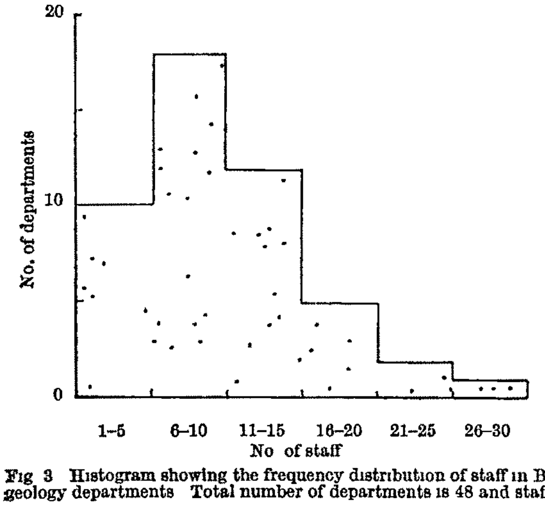

Fig 3 Histogram showing the frequency distribution of staff in British geology departments Total number of departments is 48 and staff 484

An analysis of geological research in British universities and colleges[5] shows that only 2 per cent falls within tiers I and II in Fig 2 Of this, almost half is accounted for by one university—the only one which, to judge from its calendar, has succeeded in establishing a viable Earth sciences department An analysis of the number of academic staff in British geology departments[5] shows a skewed distribution with a mode in the range 6–10 (Fig 3) This is almost certainly too small to support a three-tier hierarchy of the kind shown in Fig 2 Such a scheme would, however, become a theoretical possibility if the number of geology departments was halved and their modal size doubled. Whether they actually succeeded in introducing the scheme would, of course, depend on their willingness and ability to reorganize Better utilization and access to equipment and library resources could be an important by-product of the proposed concentration of geological effort

Needless to say, the voluntary liquidation of half the geology departments in Britain baffles the imagination. It is more probable that geophysically oriented planetary science departments will spring up independently of classical geology They will recognize that the crust of the Earth is the most sensitive meter of events in the interior over the greater part of geological time And the geologists will find their data incorporated into planetary schemes which they have had no part in constructing, partly because they have declined to attempt large-scale synthesis themselves and partly because they have insufficient knowledge of pure science Geology itself will then have been reduced to the status of a technique A similar fate may be awaiting other subjects the conceptual framework of which is still historico-descriptive

I am grateful to several fellow-workers for their thoughtful comments on early drafts of this communication

Yours sincerely,

A D STEWART

FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Monday, March 11

Society of Chemical Industry, Microbiology Group (joint meeting with the Colloid and Surface Chemistry Group, at 14 Belgrave Square, London, SW1), at 5 30 p m —Dr D A Haydon "Some Recent Developments in the Study of Biomolecular Lipid Films"

Institution of Electrical Engineers (joint meeting with the Automatic Control Group of the I Mech E , and the Institute of Marine Engineers, at 1 Birdcage Walk, Westminster, London, SW1), at 6 p m —Meeting on "Roll Stabilisation and Auto Pilots in Marine Engineering Application"

Monday, March 11—Thursday, March 14

Institute of Metals (at Church House, Great Smith Street, London, SW1)—Spring Meeting

Tuesday, March 12

Institution of Electrical Engineers (at Savoy Place, London, WC2), at 2 30 p m and 5 30 p m —Discussion Meeting on "Metrication"

Royal Institution (at 21 Albemarle Street, London, W1), at 3 p m — Professor Ronald King "Experiments—or Asking Nature Questions" (Lecture for Preparatory School Pupils from Schools in London and the Home Counties To be repeated on March 13 and 14)

Institution of Civil Engineers (at Great George Street, Westminster, London, SW1), at 5 30 p m —Informal Discussion on "Ground and Materials Investigations for Road Schemes—Needs and Methods" introduced by Mr P A Green

Institution of Electrical Engineers (at Savoy Place, London, WC2), at 5 30 p m —Discussion Meeting on "Fault Diagnosis and Maintenance"

University of London (in Mechanical Engineering Lecture Theatre "A", Imperial College of Science and Technology, London, SW7), at 5 30 p m — Professor Maria Luisa Bonelli (Florence) "Introduction The Scientific Renaissance in Florence" *

Institution of Mechanical Engineers, Automobile Division (at 1 Birdcage Walk, Westminster, London, SW1), at 6 p m —Mr H C Cox and Mr A E Norman "The Design of Automobile Door Latches"

Wednesday, March 13

Royal Institution, History of Science Discussion Group (at 21 Albemarle Street, London, W1), at 1 p m —Mr Frank Greenaway "Convergent and Divergent Research—Some Historical Contrasts" *

University of London (in Mechanical Engineering Lecture Theatre "A" Imperial College of Science and Technology, London, SW7), at 5 30 p m — Professor Maria Luisa Bonelli (Florence) "The Personality of Galileo" *

Society of Environmental Engineers (in the Mechanical Engineerin Department, Imperial College, London, SW7), at 6 p m —Mr B G Toms "Applications of Digital Computers in Environmental Engineering"

University of London (at the Institute of Archaeology, 31–34 Gordon Square, London, WC1), at 6 p m —Mr D Leigh "Sources of Maritime Archaeology—Problems of Conservation of Underwater Discoveries" *

Institute of Information Scientists (at Knightway House, 20 Soho Square, London, W1), at 6 15 p m —Mr L Corbett and Mr P J Gallagher "The Use of Commercially Available Computer Tapes for Current Awareness Services"

Wednesday, March 13—Thursday, March 14

Institution of Mechanical Engineers, Tribology Group (at 1 Birdcage Walk, Westminster, London, SW1)—Symposium on "Experimental Methods in Tribology"

Thursday, March 14

Linnean Society of London (at Burlington House, Piccadilly, London, W1), at 5 p m —Dr R Melville and Mrs F A Wrigley "Fenestration in *Monsteradeliciosa* and Its Bearing on the Morphogenesis and Colour-Patterns of Leaves", Mr T Reynolds "Seed Germination"

Mineralogical Society (at the Geological Society of London, Burlington House, Piccadilly, London, W1), at 5 p m —Scientific Papers

Institute of Petroleum (at 61 New Cavendish Street, London, W1), at 5 30 p m —Mr K R Williams "The Challenge to the Gasoline Engine"

Institution of Civil Engineers, Transportation Engineering Group (at Great George Street, Westminster, London, SW1), at 5 30 p m —Informal Discussion on "Measures for Improving Pedestrian Safety" introduced by Mr J T Duff

University of London (in Mechanical Engineering Lecture Theatre "A", Imperial College of Science and Technology, London, SW7), at 5 30 p m — Professor Maria Luisa Bonelli (Florence) "The Accademia del Cimento" *

University of London (in the Botany Theatre, University College London, Gower Street, London WC1), at 5 30 p m —Professor J de Ley (Ghent). "Molecular Taxonomy, a New Parameter on Biological Classification" *

Institution of Electronic and Radio Engineers, Education Group (at 8–9 Bedford Square, London, WC1), at 6 p m —Mr Harley R Sykes "Engineers must Manage or be Managed"

Thursday, March 14—Friday, March 15

Royal Society (at 6 Carlton House Terrace, London, SW1), at 10 30 a m daily—Discussion Meeting on "Triggered Enzyme Systems in Blood Plasma" organized by Professor R G Macfarlane, FRS

Friday, March 15

Association of Applied Biologists (in the Lecture Theatre of the British Museum (Natural History), Cromwell Road, London, SW7), at 10 30 a m — Symposium on "New Insecticides and Their Application in Public Health and Industry"

Royal Institution, Photochemistry Discussion Group (at 21 Albemarle Street, London, W1), at 1 p m —Professor D W Setser "Unimolecular Reactions and Vibrational Energy Transfer Studies with Chemically Activated Haloethanes" *

Institution of Electrical Engineers (joint meeting with the Automatic Control Group of the I Mech E , and the Institute of Measurement and Control, at Savoy Place, London, WC2), at 5 30 p m —Discussion Meeting on "Flow Measurement of Airborne Powders" opened by Mr F J Hiorns *et al*

Society of Chemical Industry, Plastics and Polymer Group (joint meeting with the South Western Section, at the College of Technology, Plymouth), at 5 30 p m —Mr G A R Matthews "Recent Advances in Extrusion"

University of London (in the Botany Theatre, University College London, Gower Street, London WC1), at 5 30 p m —Professor J de Ley (Ghent) "Evolution of Bacteria" *

Royal Institution (at 21 Albemarle Street, London, W1), at 9 p m — Professor Melvin Calvin, For Mem RS "From Molecule to Mars".

Saturday, March 16

Inner London Education Authority (at the Horniman Museum, London Road, Forest Hill, London, SE23), at 3 30 p m —"The Pulse of Africa" (Colour film on the birds, reptiles and mammals of Africa Co-Producer Pierre Koep)*

Monday, March 18

Institution of Electrical Engineers (at Savoy Place, London, WC2), at 10 a m —Colloquium on "Threshold Extension Techniques"

Society of Chemical Industry, Pesticides Group (at 14 Belgrave Square, London, SW1), at 5 p m —Mr J A R Bates "A Review of Governmental Control in Various Countries"

University of London (at the Royal Veterinary College, Royal College Street, London, NW1), at 5 p m —Professor J R Buchanan (Pennsylvania) "Radiology of the Canine Heart" *

Institution of Electrical Engineers (at Savoy Place, London, WC2), at 5 30 p m —Discussion Meeting on "The Class Structure of the British Single-phase House Service Meter" opened by Mr A J Baggott

University of London (in the Gustave Tuck Theatre, University College London, Gower Street, London, WC1), at 5 30 p m —Professor Horst Kunze (Director General of the German State Library, East Berlin) "The Training of Scientific Librarians and Documentalists in Eastern Germany" *

Institution of Electronic and Radio Engineers, Instrumentation and Control Group (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, WC1), at 6 p m —Professor H H Rosenbrock "Control Past, Present and Future" (Inaugural Meeting)

Royal Society of Arts (at John Adam Street, Adelphi, London, WC2), at 6 p m —Professor Owen Lattimore "China To-day—Some Social Aspects" (first of three Cantor Lectures)

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Lecturers (2) (Grade II or III) in the Department of Civil Engineering —The Registrar and Secretary, The University, Bristol (March 14)

Demonstrator in Pathology—The Registrar, The University, Sheffield (March 22)

Lecturer or Assistant Lecturer (with special qualifications or interests in one of the following fields low temperature, including solid state, laser physics, X-ray crystallography) in Experimental Physics—The Secretary, University of St Andrews, College Gate, St Andrews, Fife (March 23)

Research Assistant (with a first- or second-class degree in some branch of engineering or physics) in the Department of Applied Mathematics for research in rheology—The Registrar, University College of Wales, Aberystwyth (March 23)

Chair of Experimental Physics at Birkbeck College—The Academic Registrar (A), University of London, Senate House, London, WC1 (March 28)

Chair of Physics at University College, Nairobi (University of East Africa)—The Inter-University Council, 33 Bedford Place, London, WC1 (March 31)

Lecturer (with good academic qualifications, equipped to undertake supervision of work for higher degrees, and preferably some teaching experience) in Educational Psychology—The Registrar, The University, Keele, Staffordshire (March 31)

Assistant Lecturer in Biochemistry—The Secretary of the University Court, The University, Glasgow (April 1)

Chair of Geophysics—The Secretary, University of Edinburgh, Old College, South Bridge, Edinburgh (April 1)

Chairs (2) in Biological Sciences—The Secretary, University of Exeter, Northcote House, The Queen's Drive, Exeter, Devonshire (April 1)

Staff Tutor (with a good honours degree in one of the biological sciences) in Science in the Department of Adult Education—The Registrar, The University, Hull (April 1)

Senior Lecturer or Lecturer in Mathematics at the University of Ibadan, Nigeria—The Inter-University Council, 33 Bedford Place, London, WC1 (April 3)

Lecturers (2) (preferably with interest or experience in the following fields quantitative methods, climatology, hydrology, cartography and survey) in the Department of Geography, University of Ife, Nigeria—The Inter-University Council, 33 Bedford Place, London, WC1 (April 8)

Reader (with interests in freshwater ecology, hydrobiology and/or ichthyology) in the Department of Zoology, Makerere University College, Uganda (University of East Africa)—The Inter-University Council, 33 Bedford Place, London, WC1 (April 11)

Senior Lecturer or Lecturer in Science Curriculum Development in the Institute of Education, University of the West Indies, Trinidad—The Inter-University Council, 33 Bedford Place, London, WC1 (April 11)

Lecturer in Theoretical Physics—The Secretary to the University Court, The University, Glasgow (April 12)

Lecturer/Assistant Lecturer (preferably with research interests either in learning or cognitive processes) in Psychology at the University of Hong Kong—The Association of Commonwealth Universities (Branch Office

Marlborough House, Pall Mall, London, SW1 (Hong Kong and London, April 15)

OFFICIAL FELLOW IN EXPERIMENTAL PHYSICS—The President, Magdalen College, Oxford (April 15)

UNIVERSITY LECTURERS IN EXPERIMENTAL PHYSICS (Pure or Applied) in the CLARENDON LABORATORY and in the DEPARTMENT OF NUCLEAR PHYSICS—The Secretary of Faculties, University Registry, Broad Street, Oxford (April 15)

ASSISTANT LECTURER and a LECTURER or SENIOR LECTURER (with teaching and research experience (at an advanced level for the senior post) in a branch of physiology) in the DEPARTMENT OF PHYSIOLOGY, University of Melbourne, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (Australia and London, April 17)

CHAIR OF SOCIOLOGY in the RESEARCH SCHOOL OF SOCIAL SCIENCES of the Institute of Advanced Studies, Australian National University—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (Australia and London, May 17)

MASTER to take charge of BIOLOGY—The Rector, Edinburgh Academy, Edinburgh 3

Kent Scientific Recorder

Versatile Kent Instruments for the laboratory

KENT CHROMALOG, completely self-contained and portable solid-state integration system that evaluates chromatograms accurately, immediately and automatically by providing direct digital print-out of peak areas The Chromalog renders obsolete all tedious manual methods of integration and gives far more reliable results Already specified as standard equipment for a wide variety of analytical applications, the Chromalog is used extensively in conjunction with the Scientific Recorder

KENT SCIENTIFIC RECORDER, a single-point millivolt recorder for measurement of any variable that can be expressed in terms of voltage The Scientific Recorder is a special development of the internationally familiar Mark 3 range and is designed to meet the particular requirements of research, development and academic laboratories A 36-range plug-in card is available to complement the many built-in features of this versatile instrument

Test our service – telephone Mr G H Sharp, Luton 21151, or write for details by return

APPOINTMENTS VACANT

UNIVERSITY OF THE WEST INDIES

JAMAICA

Applications are invited for (a) SENIOR LECTURESHIP or (b) LECTURESHIP in Morbid Anatomy in Department of Pathology Duties include routine work in the University Hospital and instruction in morbid anatomy to students working for the medical degree of the University under the direction of the Professor of Pathology Duties to be assumed August 1968 or soonest thereafter Salary scales (a) £2 900 to £4 100 per annum (b) £2 000 to £2,960 per annum Child allowance F S S U Family passages Triennial study leave

Detailed applications (6 copies) naming 3 referees by April 10 1968, by persons living in the Americas and Caribbean area to Registrar, University of the West Indies Kingston 7, Jamaica, and by all others to Inter-University Council 33 Bedford Place London, W C 1 Further particulars obtainable similarly (1019)

UNIVERSITY OF EAST ANGLIA

SCHOOL OF BIOLOGICAL SCIENCES

A vacancy exists in the School of Biological Sciences for a SENIOR or JUNIOR RESEARCH ASSOCIATE in INSECT PHYSIOLOGY Preference will be given to senior candidates of proven research ability but junior candidates of high academic ability will be considered The successful candidate will join a research project in the field of water relationships The appointment, which will be made as soon as possible and not later than October 1, 1968, will be for up to three years in the first instance

Applications should be made in writing giving full details of education and qualifications, together with the names of two referees and sent to the Administrative Assistant School of Biological Sciences University of East Anglia University Plain, Norwich, NOR 24B (931)

UNIVERSITY COLLEGE HOSPITAL

GOWER STREET, LONDON, W C 1

Applications are invited for the post of BASIC GRADE BIOCHEMIST for routine chemical pathology laboratory The department is particularly interested in the application of automation and the use of computing techniques and the post offers good all-round experience The department is due to move to a new laboratory within the year

Applications with names of two referees, to Assistant Secretary (959)

UNIVERSITY OF MANCHESTER

MANCHESTER, 13

SENIOR LECTURER IN PHYSIOLOGY

Applications for this post are invited from graduates in Physiology, Biochemistry or related subjects or persons with a medical qualification registrable in this country Duties commence as soon as possible after July 1, 1968 Salary range per annum £2 520 to £3,415 F S S U

Particulars and application forms (returnable by March 29) from the Registrar Quote Ref 25/68/Na (997)

CSIRO

COTTON AGRONOMIST (MALE)

AUSTRALIA

DIVISION OF LAND RESEARCH

KIMBERLEY RESEARCH STATION

GENERAL Kimberley Research Station, which is jointly operated by the Commonwealth Scientific and Industrial Research Organization, Australia, and the Department of Agriculture, Western Australia, is situated 12 miles from Kununurra in the northern part of Western Australia Research at Kimberley provided the technical foundation for the recent development of irrigated agriculture on the Ord River, where in 1966/67 over 12,000 acres of cotton were grown The function of the Station continues to be that of serving the irrigation project and of research into the principles of irrigated tropical agriculture

Over the next few years it is anticipated that Kimberley Research Station will maintain ten graduate scientists Of these positions, one is in cotton agronomy, one in cotton breeding, and two others are closely associated with the cotton research programme in the fields of soil fertility and entomology The Station maintains a small fibre-testing unit

DUTIES The appointee will be required to initiate and develop a research programme in the agronomy of irrigated cotton, with special reference to agronomic and environmental effects on fibre quality

QUALIFICATIONS Applicants should have a degree in Agriculture or a related biological science, and a Ph D degree, or postgraduate research experience of equivalent standard and duration, supported by satisfactory evidence of research ability, in cotton research Preference will be given to applicants with experience and interest in problems of fibre quality

SALARY Depending upon qualifications and experience, the appointment will be made within the salary ranges of Research Scientist, $A5,250–$A6,622 p a or Senior Research Scientist, $A6,892–$A7,974 p a Promotion within CSIRO to a higher classification is determined by merit

CONDITIONS Fares paid for the appointee and his dependent family. Further particulars supplied on application

Applications (quoting Appointment No N620/62), and stating full name, place, date and year of birth, nationality, marital status, present employment, details of qualifications and experience, together with the names of not more than four persons acquainted with the applicant's academic and professional standing, should reach

Mr R F Turnbull,
Chief Scientific Liaison Officer,
Australian Scientific Liaison Office,
Africa House, Kingsway,
LONDON, W C 2, by the **5th April, 1968** (1015)

Plastics Division

EXPERIMENTAL OFFICER

Electronic Apparatus Group

We have a vacancy in the Electronic Apparatus Group serving the Research Laboratories at Welwyn Garden City for an Experimental Officer Applicants preferably should be in their twenties and have experience in applying electronic systems to research problems H N C is desirable but not essential

Conditions of service include a 5 day week, Pension Fund and Profit Sharing Scheme Assistance towards removal expenses and a temporary lodging allowance would be payable to a married man

Please apply to
O. Cheesmer, Personnel Department,
Imperial Chemical Industries Limited,
Plastics Division,
Bessemer Road, Welwyn Garden City, Herts.
or telephone. Welwyn Garden 23400, Ext. 2505.

THE QUEEN'S AWARD TO INDUSTRY

(974)

BEECHAM RESEARCH LABORATORIES
BROCKHAM PARK, BETCHWORTH, SURREY

have the following vacancy in the Immunochemistry Department at their fundamental research establishment for a

RESEARCH IMMUNOLOGIST

to undertake research as a member of a young and enthusiastic team in the field of allergy, with particular reference to *in vivo* aspects of the mechanism of the allergic reaction

Research experience in immunology is preferred, but not essential, as the person appointed will be encouraged to develop his or her own approach to the problems involved

A good Honours Degree in a biological science is necessary, and postgraduate experience would be preferred

Beecham Research Laboratories is part of the Beecham Group and is situated in a pleasant area of Surrey within easy reach of London There has been steady growth over the past years and this is expected to continue There are excellent dining facilities and a flourishing sports and social club

A competitive starting salary is offered, which will be reviewed regularly, and we offer generous fringe benefits which include profit-sharing and a non-contributory pension scheme

Please apply stating briefly age, qualifications and experience to **The Head of the Personnel Department, Beecham Research Laboratories, Brockham Park, Betchworth, Surrey.**

(948)

SCIENCE RESEARCH COUNCIL

THE RUTHERFORD LABORATORY, Chilton, Didcot, Berks.

PHYSICIST OR CHEMIST

with research experience in **MAGNETIC RESONANCE**

is required for position as

RESEARCH ASSOCIATE

The Rutherford Laboratory is Britain's largest centre for research in elementary particle physics The Laboratory's 7 GeV proton accelerator, NIMROD, has been in operation for several years, enabling physicists from universities and from the Laboratory itself to complete much significant work in this field, including experiments in which a number of new unstable fundamental particles have been discovered using a polarized proton target It is with such targets that the present post is concerned

Existing polarized targets contain such a small proportion of free protons (only about 1 in 30 of all nucleons present), that they have very limited use with regard to the wide range of spin-dependent interactions which can in principle be studied using polarized targets

The development of better targets is thus very important to the future work of the Laboratory Progress in this direction must be based on fundamental research on all the factors affecting dynamic nuclear polarization, including relaxation times, spin diffusion, and the properties of a wide range of proton containing materials and paramagnetic centres Progress will also depend on the use of advanced cryogenics at helium 3 temperatures, and special superconducting magnets

The physicist or chemist appointed to this research post would join a group already working at the Laboratory on these problems Applicants will be expected to have gained a first or good second class honours degree, a doctorate would be an advantage

Research Associates are appointed for a period of 3 years and are paid a fixed salary for each year of the Associateship the salary will be based on the broad lines of the Scientific Officer Class, at present ranging from about £1,250 to £2,300 per annum according to age, qualifications and experience

The post is superannuable under F S S U Daily travel and restaurant facilities are available Housing may also be available **Please send a postcard for application form to Mr. G. N. Pickles, The Rutherford Laboratory, quoting reference 126/34.**

(1001)

Project Leader Physics

The Research and Development Department has been responsible for major advances in spectroscopic instrumentation and as a result of planned expansion now require a Project Leader for work on the design of spectroscopic instruments

The Department has over 100 members and generous technical assistance is available from the drawing office, model shop and electronics section

This appointment calls for a Physicist with a good honours degree and either postgraduate research or industrial experience together with a general interest in experimental physics or spectroscopy

The Company has a world-wide reputation for precision and reliability in the field of instrumentation and is a rapidly expanding member of a powerful international group An attractive salary will be offered and generous assistance given with removal costs

UNICAM

THE QUEEN'S AWARD TO INDUSTRY 19 6

Please apply Director, Research and Development,
Unicam Instruments Ltd , York Street, Cambridge (989)

UNIVERSITY OF LONDON KING'S COLLEGE

DEPARTMENT OF GEOGRAPHY

(1) Applications are invited for places in the postgraduate section of the Geography Department Students may be registered for the M Sc or M Phil degrees with possible opportunity to transfer to Ph D It is hoped that some grants will be available for studies in both Physical and Human Geography

(2) Applications are also invited for the positions of Research Assistant and Graduate Assistant in the East African Rainfall Project Minimum salary £1 000 and £700 respectively with higher rates dependent on age, qualifications and experience It is desired to make these two appointments as soon as possible

Full details may be obtained from the Head of the Department, Professor J C Pugh King's College London Strand, W C 2, to whom application should be made Candidates should specify whether they are interested in (1) or (2) (960)

UNIVERSITY OF NOTTINGHAM

DEPARTMENT OF CHEMISTRY

S R C RESEARCH ASSISTANT

Applications are invited from graduates in Chemistry for the post of Research Assistant to Dr G D Parfitt The work involves an experimental study of the coagulation of colloidal systems involving mixtures of solid particles (heterocoagulation) and is supported by a grant from the Science Research Council The salary will be according to qualifications but will not exceed £900 per annum

Applications, quoting two referees should be made as soon as possible to Dr Parfitt, from whom further particulars may be obtained (956)

SOUTH-WEST METROPOLITAN REGIONAL HOSPITAL BOARD

SENIOR GRADE PHYSICIST required to act as Radiation Protection Officer for the Region Applicants should have experience in Health Physics and/or Diagnostic Radiology The successful applicant will be based initially on the Radiological Protection Service at Sutton but will be transferred to Guildford when the Physics Services there are expanded Salary scale £1 833 by £82 (2) by £87 (1) by £88 (1) by £92 (1) to £2 276 per annum London Weighting allowance of £75 per annum will be payable while based at Sutton

Application forms and further details of the post can be obtained from the undersigned (S2) at 40 Eastbourne Terrace, London, W 2 (or telephone 01-262-8011 Ext 166) Completed applications to be returned by March 20

E G BRAITHWAITE,
Secretary
(975)

UNIVERSITY OF BRISTOL

TECHNICIAN or SENIOR TECHNICIAN required for Tsetse Research Laboratory Veterinary School, Langford (12 miles south of City) Interest in insect colonies climatic control and biological techniques desirable Salary Technician £653 to £938, Senior Technician £912 to £1,150 plus £30/£80 supplementation for recognised qualifications

Applications, giving full details and the names of two referees, should be addressed to The Director, Tsetse Research Laboratory, Langford House, Langford, Bristol (999)

UNIVERSITY OF MALAYA

CHAIR IN THE DEPARTMENT OF MATHEMATICS

Applications are invited for appointment to the Chair in the Department of Mathematics in the Faculty of Science The post will become vacant when the present incumbent leaves at the end of February, 1968, on resignation Candidates should have high academic qualifications and wide experience in teaching and research Administrative experience in running a Department is essential The successful candidate is expected to assume duty as soon as possible

EMOLUMENTS (approximate sterling equivalents at current exchange rates) are

(a) Salary There is a range of basic salaries, to a point on which a Professor is appointed depending on his qualifications and experience These are £2,882, £2,980, £3,077, £3,175, £3,273 £3,370, £3 468

In addition, the following allowances are payable

(b) Variable Allowance 35 per cent of basic salary, subject to certain maxima depending on marital status Minimum £244 per annum, maximum £651 per annum

(c) Inducement Allowance (if awarded), varies up to £1,628 per annum (In exceptional cases an inducement allowance exceeding this amount may be granted)

HOUSING will be provided if available, for which a rent of £163 to £204 per annum will be charged

PROVIDENT FUND Staff member contributes 5 per cent and University 15 per cent of basic salary

Further particulars and application forms are obtainable from the Association of Commonwealth Universities (Branch Office), Marlborough House Pall Mall, London, S W 1

The closing date for the receipt of applications in London and Kuala Lumpur is April 8, 1968
(982)

UNIVERSITY OF MALAYA

FACULTY OF ENGINEERING

Applications are invited for appointment to the following Chairs in the Faculty of Engineering

CHAIR OF ELECTRICAL ENGINEERING
CHAIR OF MECHANICAL ENGINEERING

Candidates offering themselves for the above Chairs should be corporate members of the Institution of Electrical Engineers and the Institution of Mechanical Engineers respectively and have experience in teaching and research at university level Administrative experience will be an advantage

EMOLUMENTS (approximate sterling equivalents at current exchange rates) are

(a) Salary There is a range of basic salaries to a point of which a Professor is appointed, depending on his qualifications and experience. These are £2,882, £2,980, £3,077, £3,175, £3,273 £3,370, £3,468

In addition, the following allowances are payable

(b) Variable Allowance 35 per cent of basic salary, subject to certain maxima depending on marital status Minimum £244 per annum, maximum £651 per annum

(c) Inducement Allowance (If awarded), varies up to £1 628 per annum (In exceptional cases an inducement allowance exceeding this amount may be granted)

HOUSING will be provided, if available, for which a rent of £163 to £204 per annum will be charged

PROVIDENT FUND Staff member contributes 5 per cent and University 15 per cent of basic salary

Further particulars and application forms are obtainable from the Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W 1

The closing date for the receipt of applications in Malaya and London is April 8, 1968 (981)

POSITION OPEN

CURATORIAL ASSISTANT To act as Museum Guide for school groups and to assist in organization care and display of rock mineral and fossil collections

QUALIFICATIONS B Sc or M Sc in Earth Sciences , artistic talent desirable

SALARY Commensurate with experience and potential

WRITE INQUIRIES TO Chairman, Museum Committee, Department of Geology, University of Alberta, Edmonton Alberta, Canada
(572)

Cutting Cakes Blindfold

THE increasing self-consciousness of science policy is, of course, entirely to be welcomed even if, now and again, those responsible for making policy decisions that affect science are a little too inclined to congratulate themselves about it It would be wrong, however, to believe that the potentially good effects of this self-consciousness have already been reflected in the pattern of expenditure on science in countries such as Britain People say, with every appearance of solemnity, that their immediate concern is to establish priorities for expenditure in science and then to see that expenditure follows the appropriate rules, but there are still plenty of examples of how expenditure in crucial fields of science is still more determined by historical than by rational considerations This week, which has seen the regular meeting of the planning group of the European Space Research Organization in Paris and mounting excitement among astronomers about the pulsating radio stars discovered at the Mullard Radio Astronomy Observatory, is a splendid occasion for reflecting that the British pattern of expenditure on space, astronomy and related activities is, to say the least of it, illogical

In Britain, the Science Research Council is the chief source of funds for the support of fundamental research and, quite properly, the council has delegated much of its responsibility to the Astronomy, Space and Radio Board (For practical purposes, the substantial sums of money spent on space research by the Ministry of Technology do not impinge directly on the work of the universities, although much of the work carried out in government establishments is, as it should be, of long-term importance to basic research) In round numbers, the Astronomy, Space and Radio Board of the Science Research Council is responsible for giving advice about the allocation of £10 million a year to various kinds of activities, but it is exceedingly hard to be assured that the pattern of expenditure in this field is one that a body of rational and sensible people would deliberately have chosen if it was really free to choose

For one thing, the board is formally responsible for the expenditure of rather more than £4 million a year (in 1967–68) on ESRO—some 12 per cent of the budget of the Science Research Council as a whole During the same period, the Science Research Council is likely to have paid the Ministry of Technology £1 2 million for engineering work on satellites and for the launching of sounding rockets, and rather more than half a million pounds for the development of upper atmosphere and satellite research in the universities At the same time, the Radio and Space Research Station at Slough will have cost just over a million pounds to run, mostly on recurring expenditure Pure astronomy, as it may be called, is a comparatively poor relation In 1967–68, the cost of running three observatories—Greenwich, the Cape of Good Hope and Edinburgh—was estimated a year ago to be just over a million pounds, and during the same period universities were expected to receive from the Science Research Council some £600,000—more than three-quarters of it for capital equipment such as new kinds of radio telescopes In other words, university astronomy, conventional astronomy and radio astronomy combined cost rather less than 10 per cent of what the Astronomy, Space and Radio Board has to spend, and rather less than 8 per cent of what the Science Research Council spends each year on the support of research in the universities

Although it is easy enough to see how this pattern of expenditure has grown up, and easy to be sympathetic with those who take the line that there is now very little to be done to change it, it is hard to imagine that even the most cursory cost–benefit analysis would justify the expenditure of so much on space research, which has so far been useful but not spectacularly productive so far as Britain is concerned, and comparatively so little on astronomy It is not, after all, as if there were no opportunities for constructive expenditure in astronomy It is hard, for example, to believe that one 98-inch telescope in Sussex and the promise of a larger instrument in Australia will satisfy the needs of British astronomers in the decade ahead There is also good reason to fear that not enough is being spent on the development of instruments which can increase the productivity of optical telescopes and on the research and development from which new techniques must come And what, in any case, about radio telescopes ? The Science Research Council has been extraordinarily far-sighted in the past decade in its support for radio astronomy, but the financial uncertainties of the past few months may yet be reflected in an awkward hiatus unless somebody is resolute

But space research, like astronomy, sustains a demand for new expenditure The space research groups in the universities would no doubt be able to spend quite comfortably twice as much as they have been getting from the Science Research Council The question which they and others should ask, however, is whether, in circumstances in which no amount of spending in Britain can hope to yield a harvest of scientific information comparable with that being gathered in the United States, there would be any good purpose in a substantial increase of expenditure on space research

But this, of course, is not the real question The reason why the pattern of expenditure on astronomy, space and radio is lopsided is that the Science Research Council is bound—or considers itself bound—to chariot wheels created in the past The expenditure on ESRO must, in this spirit, be reckoned more as a political commitment than a deliberate expenditure (which is not to say that Professor Herman Bondi may not yet salvage something of importance from ESRO) And is it possible, anyway, that the Science Research Council should at this stage ask some of the subversive questions about the institutions which it administers which might lead to a radical recasting of the lopsided pattern ? If, for example, a large part of the work of the Radio and Space Research Station and the Greenwich Observatory is no longer determined by the need to provide public services—time signals and the like—is there not a case for transferring these establishments to the universities ? It is true that in the past few months the Greenwich Observatory has taken important steps to make the Isaac Newton telescope accessible to university astronomers, but there is probably a long way to go before the observatory will play its full part in stimulating and sustaining university research in astronomy It would also be good to know just precisely how the work of the Radio and Space Research Station at Slough, costing more than 10 per cent of what is spent in this whole field, contributes to the greater good

To ask all these questions is in the first place merely to suggest that they should be asked and answered If the new broom of self-conscious planning in research and development is to be taken seriously, the Science Research Council must make a determined effort to ensure, first, that it is getting value for the money it spends on organizations like ESRO and, second, that it is spending all that the circumstances require on activities where there are now immediate and promising opportunities for generosity Nobody at this stage would be surprised to learn that only half or even less than half of what is at present being spent on astronomy, space and radio is likely to yield immediate and tangible benefits in science The alarming thing, of course, is that there is every likelihood that expenditures in other fields of science have equally unbalanced distributions The problem of translating the will resolutely to pursue rational priorities in expenditure in science into action is uncommonly difficult Everybody would benefit, however, if the coincidence of a straitened budget and the recent surge of excitement in astronomy served somehow to draw attention to the need that expenditure should be more rational

Are Students Subversive?

From Berkeley to Prague, students in universities are drawing attention to themselves and to their relationship with university authorities in ways which are, it is true, characteristically different but which nevertheless have more than a little in common In Berkeley, the explosions of the past two years have now been reasonably battened down and the report of the Faculty Student Commission on University Governance which has just appeared (see page 1005) promises to provide at least a basis on which the development of the Berkeley campus can continue without too much serious interruption In Eastern Europe, by contrast students appear to be less concerned about their own relationship with the universities than with more general questions of politics and society In Britain, in this respect more like the Californian universities, students are fighting or pretending to fight on two fronts—they are protesting at what seems to be their impotence in the making of university policy and, at the same time, are embarking on foolish and sometimes wild attacks on those rash enough to visit them—Cabinet ministers and officials from foreign embassies It remains to be seen whether the relationship between British students and the rest of British society will be further inflamed by the statement by Mr Patrick Gordon Walker, Secretary of State for Education and Science, a week ago that the taxpayers who provide students with grants cannot be expected to approve the way in which things are now being managed Given his long record for choosing the wrong words in public, however, Mr Gordon Walker himself may now agree that it might have been better to say nothing

The truth is, of course, that it is foolish to behave as if the problems which are arising in a host of universities, not just in Britain, can be chased away with a few prim admonitions There are three quite separate causes of tension between students and the society in which they are embedded, and the chances are that these will become more and not less preoccupying as time goes on First, as developmental biologists must by now be tired of saying, people are maturing earlier and, perhaps more important, the increasing complexity of industrialized societies is continually requiring still more mature behaviour from partly mature people In the circumstances, nobody should be surprised that students waste a lot of time and energy on questions about the use of drugs or the rate at which they should be paid for living in what their critics consider to be an unwarranted condition of idleness and luxury Second, the increasing population of the universities and the increasing diversity of those who attend them have created among students a greater will to be concerned in the planning of universities and in the making of academic policy So long as universities were monkish places, intended to make academics, it was comparatively easy for students to accept the established pattern of the university curriculum Now that students at universities are quite properly concerned with other matters, however, it is understandable that they should want some say in the organization of the curriculum and even in the conduct of the teaching programme The question for university faculties to answer is how much they should yield to the students or, better, how they should devise new means of winning the collaboration and not just the acquiescence of students in forward planning. The third class of problems is probably not a problem at all but something that universities will have to live with Indeed, the most surprising feature of university politics is that universities have usually been much less concerned with the problems of the societies in which they are embedded than they could or even should be Outsiders often find them irritatingly indifferent to the real world and it will be no bad thing if the reawakening of political interest among students turns out to be a brash foretaste of a more solid concern for contemporary problems in the universities as a whole In this respect, British universities are more backward than those in the United States (where faculty members commute to Washington very often) and Eastern Europe

So what is to be done ? The most immediate need for change is in the relationship between students and the university machine The strength of the report of the Faculty Student Commission at Berkeley is that it suggests ways in which students can be fitted into the apparatus for making decisions at all levels on the campus The object, the report argues, is not so much to create formal apparatus by which the conflicting interests of students and the faculty can be brought into confrontation, but rather to create machinery which will somehow remind both sets of people of their mutual interest in a smoothly functioning machine for teaching It remains, of course, to be seen how much of the commission's report will eventually be embodied in the constitution of the University of California, but the mere fact that it has been written is historic in itself In Britain, the nearest tangible step in this direction is that taken at the London School of Economics, where students are to be appointed to a number of committees but specifically not the committees concerned with academic policy, and there are some reasons to believe that other universities will follow suit The trouble, of course, is that it will take time for students to appreciate that devices like these can serve as real instruments of power and possibly even longer for teachers to learn by experience that students have helpful as well as interesting things to say And in the long run, of course, it is hard to see how students can be entirely excluded from academic policy It is no longer sensible for the faculty to attempt to buy off students with tea and muffins in the afternoon and sherry before dinner Until all these things are acknowledged, tension and trouble are likely to persist.

Discussions in Paris

THE ministerial meeting organized last week in Paris by the Organization for Economic Cooperation and Development seems to have been the sort of sucess these meetings generally are The meeting, ttended by ministers of science and education from most of the OECD countries, discussed problems of the technological gap, of fundamental research policy and f information retrieval and dissemination Mr Patrick Gordon Walker, the British Secretary of State for Education and Science, agreed after the meeting that some progress had been made In particular, it seems that one of his own suggestions met with some enthusiasm This was a proposal for the establishment of a European Research Council similar in nature to the ones which operate in Britain

The funds for such an agency would be provided by what the background paper to the conference calls a "matching fund" This would presumably involve the contributions of sums of money to a central organization from the countries of OECD The money would then be distributed to existing research groups in OECD countries As Mr Gordon Walker pointed out, "It would involve a central agency I am sure that such an agency must be composed mainly of scientists and have autonomy in the arrangement of its business and the disposal of whatever funds it may have at its command " The beauty of the idea as far as Europe is concerned is that it would not involve the formation of any new institutions, as the background paper points out, it would instead encourage the development of existing research groups of outstanding quality The paper suggests two fields in which experiments might be carried out, computer science and neurobiology and psychobiology The meeting in Paris agreed that a serious study of the setting up of such a research council in Europe should be carried out during the next year

The meeting also spent some time discussing the technological gap between the United States and other OECD countries The background paper makes a determined effort to define the gaps, concluding that the term can be taken to include almost any feature of life which is different on the other side of the Atlantic Educational systems, the conditions under which government support is given, the techniques of management, scientific and technological capability and the size and homogeneity of the market in the United States are all quoted as causes of the gap Given this diversity, it was hardly surprising if the ministers were unable to define easy ways of reducing the gap Mr Anthony Wedgwood Benn, the British Minister of Technology, came back to the idea of a European Technological Institute This time the institute, which has become almost an obsession for British ministers, was described as a means by which Europe could carry out effective long term planning If Europe could carry out this task of long term market forecasting correctly, Mr Benn said, "it would then be possible to compare the existing need against the capability to meet it" At this point firms would look to their own expansion plans, and see the need for cooperation on a European scale But Mr Benn made it clear what the technological institute would not be—it would not be an academic research institute "Such laboratories may be desirable for their own reasons, as at CERN, but they do not close any technological gaps "

Gas Bonanza

THE British Gas Council has at last reached agreement over the price it is prepared to pay for natural gas from the North Sea So far, the agreement affects only one of the companies lucky enough to discover gas, the Phillips Group The price agreed is 2 87*d* a therm, on a 25 year contract affecting supplies of 350 million cubic feet of gas a day. This is much like the figure which has been widely quoted since negotiations started eighteen months ago, with perhaps a slight upward revision because of the effects of devaluation. The original contract signed with British Petroleum at 5*d*. a therm for 100 million cubic feet a day was obviously not going to be repeated—equally, the Gas Council's original offer of 1·8*d*. per therm was probably unrealistically low. Both Phillips and the Gas Council seem now to be satisfied.

This is entirely as one would expect. Despite accepting a price which some would consider low, Phillips is going to make a very handy profit. When the gas is flowing at full speed through the pipes, it will be collecting £1 million about every three and a half weeks. The investment probably cost £25 million, a sum which it will earn within two or three years. After that, all being well, it will be pure profit. But it is only fair to point out that it may not be quite so easy—the field may need further development in order to keep the gas flowing. And Phillips can fairly claim that without a generous return it would never have made the investment in the first place.

With luck, the agreement with Phillips will encourage the other companies involved to come to terms. Arpet, which shares Phillips's field on the Hewett Bank, must surely now settle on the same terms. And the other companies, Shell/Esso and Amoco (which shares its find with the Gas Council), must also now knuckle under. These finds are somewhat farther out in the North Sea, and rather deeper, so that Shell/Esso and Amoco may be able to squeeze a little more out of the Gas Council. But it is now the Gas Council which is the master, principally because the reserves of gas which have been found far outstrip demand. Even the Phillips find will be enough to supply one-third of present British demand for gas. By 1971, demand is expected to double, but even so there is likely to be something of a glut of natural gas for a decade or so. The oil companies negotiating with the Gas Council thus find themselves in a conspicuously weak position which no amount of bluster can conceal.

This should also have the effect of strengthening the case put forward by the Central Electricity Generating Board for a greater share of the gas. If the CEGB wins its case—and in the long run it can hardly fail—the principal loser will again be coal. But nuclear power, just emerging from a long and bitter struggle with the coal lobby, may now find itself embroiled in a similar struggle with gas. For the ordinary gas consumer, the Gas Council can only promise jam tomorrow. In the short term, it says, gas prices are certain to rise, in part because of the crisis in the Middle East. In the long run, Sir Henry Jones of the Gas Council thinks gas prices will fall, but less optimistic observers fear that natural gas will do no more than prevent an upward spiral in prices. To the domestic consumer, paying almost ten times as much as the Gas Council is paying Phillips for each therm of gas (the average price of gas to the consumer is about 25·5*d*. per therm), this seems very hard to accept.

Exploiting Technology

THE role of public research and development services in British technology has been evaluated by the Institution of Professional Civil Servants, and recommendations for improvements are published this week in a report entitled *Exploiting Technology*. The executive committee of the institution decided to look into the way research and development in the public sector are operating, with the belief that it could make proposals for action as well as examining the facts. The 70,000 members of the institution work in all branches of the public sector—government departments, public bodies, and with the research councils.

The report begins with the assumption that research and development are the key to any nation's prosperity, and Britain is not making the best use of its resources in this direction. Left to itself, industry does not undertake the necessary research and development, and although there are various forms of government encouragement—through such bodies as the Industrial Re-organization Corporation, the National Research Development Corporation and research associations and advisory services—there is scope for much more. The report discusses suggestions that more research and development should be taken from the public sector by industry, and concludes that little would be gained from this, as ideas are often badly thought out or too long-term to be of practical value in the near future. Any shake-out of staff from the public sector would in fact have very little effect in industrial research. Buildings, equipment and experienced staff are already in existence in the public sector, but although many of the organizations have been doing a good job, the report suggests that most of them could be effectively streamlined.

In its recommendations, the report calls first of all for a clear statement of priorities from the Government, so that money is not wasted on research that is too expensive or will shortly be abandoned. After this, closer cooperation between public sector research and industry is the main theme. Rationalization of organizations doing similar research work and industries with similar problems is called for, together with closer working of public bodies with industry so that research teams investigating problems in industry and industrialists are brought into research councils and the management of government establishments. A central body, organized by the government, should take charge of the coordination of scientific and technical information and its dissemination, but commercial security must be safeguarded. Exchanges of manpower are desirable, and the report suggests that mobility can be encouraged by workers having transferable pension schemes. Refresher courses are recommended for qualified staff, and it is suggested that firms will benefit if scientists and engineers are trained in management techniques. With the realization that streamlining of the public sector will affect members of the institution, the report states that there must be adequate preparation for the social problems involved in the changes of employment resulting from this reorganization.

Doctorates in Physics

THE Royal Society has just published a report on th training of PhD students in physics. The report form part of a Royal Society survey, started in Novembe 1965, on postgraduate training in science and technology in the United Kingdom. Sub-committees wer set up to investigate the content and quality of trainin for the PhD degree in six groups of subjects—biology, chemistry, engineering, earth sciences, mathematics and physics The report of the chemistry group was published in March last year, and the Royal Society hopes that the reports of the other four groups will appear before the end of 1968

The physics sub-committee, under Professor C C Butler of Imperial College, limited its attention to a study of postgraduate lecture courses attended by physics PhD students and a comparison with courses available in graduate schools in the United States Butler sent a letter to the heads of all university physics departments asking for brief details of postgraduate lecture courses attended by PhD students, and it is on the replies to this letter that the new report is based Rather surprisingly, the sub-committee did not ask the PhD students themselves for views on postgraduate training

The present undergraduate course is no longer sufficient to prepare students for a full professional career, and the report approves of the recent trend towards lecture courses for PhD students. The sub-committee realizes that it is often difficult for experimentalists to complete a PhD within the three years of a Science Research Council maintenance grant, and any extension of course work will increase the difficulties It therefore recommends that provisions for fourth year grants should be made in certain cases

Comparison with graduate schools in the United States—largely based on the opinions of British physicists who have worked in American universities—revealed no evidence that the standards of PhD training are significantly different in the two countries There seems, however, to be some foundation for the widely held view that the American experimentalist has a broader theoretical knowledge than his British counterpart

Some of the value of these six studies of postgraduate training in science and technology is being lost because the organization of the surveys is being left to the discretion of the individual chairmen The chemistry report, for instance, was based on enquiries among university professors and six centres of chemistry in the United States, while the more ambitious sub-committee for engineering has written to 1,900 postgraduates and to 90 companies and institutions This will make comparison of the training afforded to students in different subject groups difficult

Soul-searching for ESRO

On Wednesday and Thursday of this week there was a meeting of Alternates of the European Space Research Organization (ESRO) where the main preoccupation was expected to be the continuing exercise of preparing ESRO's case (see *Nature*, **216**, 696, 1968) for the European Space Conference in Bonn in June It is hoped that here a policy and programme for European space will finally be settled At the last European Space Conference, in Rome last July, a special committee was set up to evaluate the various proposed projects in European terms This Advisory Committee on Programmes was chaired by J P Causse from the French aerospace industry, supported on the technical side by five independent experts, and it produced its report at the turn of the year The ESRO Alternates were to consider it in detail at this week's meeting There seems no reason why the Causse Committee's report should not then be published

The main dilemma facing ESRO is whether its activities should be substantially redirected towards "useful" satellites, such as the communications satellite sponsored by CETS (the European Conference for Telecommunications by Satellite), or retain its original purpose of providing scientific research opportunities beyond the resources of individual countries The immediate clash is between the European communications satellite and the large astronomical satellite as candidates for ESRO's major project for its first decade. It seems out of the question that both projects could be adopted at the present financial level of European space organizations It will be interesting to see what the Causse Committee has had to say about their relative merits

Full Stop on Decimals

Britain's plans to adopt the metric system of units have run into a little local difficulty. A dispute has arisen over the decision by the Decimal Currency Board to use the full stop or point as a decimal marker, instead of the comma which is common in metric countries The British Standards Institution, which is responsible for organizing the change to the decimal system in British industry, favours the comma, combined with a space to indicate thousands The construction industry, the first to embrace metric units, has already begun to issue reports in this form If the Decimal Currency Board is to have its way, both the BSI and the construction industry will have to think again

The traditional system uses a full point for the decimal sign and a comma for indicating thousands, the new system supported by the BSI would use the comma for the decimal sign, and each group of three figures would be separated by a space Thus the Decimal Currency Board would write 5,650·3286 and the BSI would prefer the form 5 650,328 6 It is no secret that the joint metrication committee of the Ministry of Technology, an advisory body under the chairmanship of Mr A H A Wynne, favours the system adopted by the Decimal Currency Board Unlike most aspects of the metric system, there has so far been no international decision over which system to adopt, and this has made the committee's decision a difficult one In reaching it, it took into account a number of factors

First, there was the evidence provided by two questionnaires sent out by the BSI The first, to the general engineering industry, produced inconclusive results The second, which included financiers and merchant bankers, produced, predictably enough, a result in favour of traditional practices The bankers felt that a system using empty spaces was an open temptation to fraud The Decimal Currency Board—a notably conservative body—was swayed by much the same argument in favour of the traditional system The Confederation of British Industry is also said to prefer the traditional system In spite of this, the BSI continues to favour the space/comma system, and has written to the Decimal Currency Board to say so The Ministry of Technology's answer to this is to say that, as long as there is no international system, it would be best to stick to the existing system If the BSI's appeal fails, it is likely that the construction industry will have to go back on its decision to use the space/comma system

When an international conference is called, of course, it is not impossible that yet another system will emerge There is, for instance, some support to be found for a system which would use a colon to indicate the decimal point But this is still highly speculative Meanwhile, the Ministry of Technology and the Decimal Currency Board say that Britain should stick to conventional practices Colonel J S Vickers of the BSI, the keenest supporter of the space/comma system, will find it difficult to change their minds

Physics Exhibition 1968

by Professor S. Tolansky

THE 52nd exhibition arranged by the Institute of Physics and the Physical Society at Alexandra Palace, London, during March 11–14 was, true to an old tradition, essentially a British show Foreign contributors could be counted on one hand Noteworthy was the distribution of exhibitors, for while industry supplied a little over a hundred, there were in addition no fewer than 45 government-sponsored laboratories represented and some 40 separate higher educational establishments (universities, colleges of technology and teaching hospitals) The encouragement of the latter by the offer of free stands is highly praiseworthy By far the dominant single contributor to the exhibition was the United Kingdom Atomic Energy Authority, which controlled 23 separate stands with displays from 7 different stations

In accordance with usual practice, participation was by invitation Because all exhibits are expected to illustrate novel features, and educational displays require to be passed by referees, the overall standard was both original and attractive The items displayed ran to nearly a thousand, with a distinct bias towards electrical and electronic devices Vacuum technology came off reasonably well, although there was some very expensive equipment, which would be too sophisticated for the university laboratories Quite a number of pieces of microwave equipment and several electrical bridges were shown

One notable item was a Mullard infrared microscope, easily adjustable and using a liquid air cooled indium antimonide detector Performance was attractive and there are clearly many uses for this compact device Mullard also demonstrated the modulation of the infrared output from a filament lamp using yttrium iron garnet Engelhard-Hanovia demonstrated a neat sensitive optical observation device for the detection of small amounts of mercury vapour in laboratory atmospheres My distinguished former teacher, F Paschen, always used to insist in the late twenties and thirties that the mercury level in many university laboratories was a dangerous hazard

Particularly notable was the exploitation of gas lasers at light sources These seem to be quite common laboratory objects now Lasers apart, optics was not strongly represented True, there were some compact high speed cameras and a little-modified long-used optical testing interferometer, yet no special lenses, no visible light microscopes, no new optical materials, etc In fact, "classical" physics was weakly represented, although there were a microcalorimeter, a micromanipulator, a small photometer, an acoustic telemeter, a moisture recorder, cyrostats, new ultraviolet spectrometers and some applications of ultrasonics Holography was represented, but here there was nothing startling, and thin films, either their production or measurement, occupied a few displays

The educational displays with their simple "hook-ups" attracted a good stream of visitors, but here too there was a strong bias towards electrical devices It was a relief to see some fine high resolution interference fringes from Belfast, an ultraviolet radiation meter from Charing Cross Hospital, and a new optical instrument from the Royal College of Surgeons which can measure alcohol vapour down to concentrations of 400 parts per million These and numerous other clever original devices, many designed by the young research workers who were themselves enthusiastically demonstrating their own products, were a heartwarming indication that there is little need to worry about the ultimate future of British physics instrumentation The feed-in from below is certainly sound, although regrettably too electrical

The relatively wealthy government establishments laid on sophisticated devices, all beautifully constructed and magnificently illustrated Yet a lot of this quite expensive publicity polish is quite superfluous, especially in a show for professional physicists A certain number of exhibits were frankly educational, but most of these were dull One, however, a well-conceived atomic optical pumping device from Oxford University using rubidium, clearly has wide teaching applications. There were some excellent book displays in the educational section

I came away from the exhibition somewhat bewildered by the overpowering emphasis on electronic circuitry There seem to be fashions in modern physics as well as much sad disregard of classical subjects There was, for instance, only one display devoted to Mossbauer effect, but no less than ten exhibits exploited lasers Indeed, lasers occupied more space than such normally popular subjects as telemeters or cryogenics or even semiconductor devices

Information on Biodeterioration

BIODETERIORATION means the deterioration of materials of economic importance by living organisms The word was coined in America, but it is a centre at Aston University, Birmingham, which is taking the lead in informing research workers and others of developments in this particular field The centre, the Biodeterioration Information Centre, under the direction of Dr Howard Eggins, was set up in 1965 with the help of a grant of £12,000 from the Office for Scientific and Technical Information It was the first of several information centres now functioning to be sponsored by OSTI The centre is now fully operational and a press conference to publicize it was held last week—the OSTI grant runs out this year, and the organizers naturally hope that more money will be forthcoming from other sources

Some examples of biodeterioration are the attack on wood, paper, textiles and grain by fungi and insects, the blocking and corrosion of pipelines by bacteria, the growth of fungi and algae on concrete and painted surfaces, the fouling of ships and marine structures by barnacles and molluscs, the destruction of stored products by rodents, and hazards caused to aircraft by birds It has been estimated that European countries alone lose £400 million annually through biodeterioration of goods such as timber, textiles, jet fuels, paint, metals and plastics The figure must be very much higher than this for the whole world, because biodeterioration is an ever more serious problem in tropical countries The loss of stored food products from spoilage, contamination and deterioration varies from one country to another, being worst in the developing countries, but over the world as a whole it is probably about 30 per cent As the report of the US President's Science Advisory Committee on *The World Food Problem*, published last year, put it, "If only half of the estimated world loss of food grains was prevented, it would represent an additional 55 million tons or enough to make the diet of 500 million people in developing countries adequate in total calories" And the loss of food supplies is only part of the biodeterioration problem—a problem which is made worse by the interdisciplinary nature of the subject which leads to difficulties in communicating information

The Biodeterioration Information Centre hopes to help solve the problem by providing an information service to workers concerned with biodeterioration all over the world The centre collects articles on the subject selected by specialists in more than 30 countries Each item is indexed with appropriate keywords selected from a specially prepared thesaurus and is recorded in a punched card index system All the accessions of the centre, which number 2,500 to 3,000 articles a year, are listed in a classified bibliography (IBBRIS) which is published quarterly A photocopy service for inaccessible literature is operated and a question-answering service provides either IBBRIS accession numbers or, when available, author abstracts of articles in the collection A further service is the publication of original and review papers in the *International Biodeterioration Bulletin* Associated with the centre are two laboratories where research into microbiological deterioration is done Current research projects include studies on the breakdown of cellulose by fungi, the growth of fungi in high temperatures and the detoxification of preservatives by fungi and bacteria

Not for Drinking

WATER from the mains is not as pure as most people would like to think This was clearly emphasized on March 8 during the afternoon technical sessions of the sixteenth annual general meeting of the Society for Water Treatment and Examination In the rather spartan main hall of the College of Preceptors, Bloomsbury Square, the audience was told how living organisms ranging in size from viruses to beetles are contaminating water in Britain Fortunately, most of the animals involved are not known to involve risk to human health, although infectious hepatitis—a faecally excreted virus—is transmitted by water Dr S F B Poynter, senior assistant bacteriologist to the Metropolitan Water Board, suggested that not only are large numbers of potentially pathogenic organisms excreted—for example, the three types of poliovirus, and adenoviruses—but it has been shown that existing methods of sewage treatment are ineffective inactivators of these viruses A typical disinfectant, combined chloride in its various forms, is relatively useless as a virucidal agent As a result, viruses are discharged in the effluents flowing into rivers and are then borne to water storage reservoirs Trickling filters seem to be particularly inadequate, but a number of investigators have found that activated sludge treatment is more effective During the discussion Mr R W Covill of the Lothian River Board, Edinburgh, said that he knew of a case of partially and unpurified sewage being used to irrigate crops of lettuces and strawberries, and suggested that there is a need for more stringent precautions in this connexion

Animals in mains are also creating an increasing problem, which Mr I C Smalls and Mr G F Greaves of the Biology Division at the Water Research Association have investigated. According to a survey which they have undertaken, infesting animals may give rise to complaints by the appearance of individual animals at the tap, by discolouring the water with, for example, faecal pellets, or possibly by causing tastes and odours as a result of the decomposition of dead animals in the mains by bacteria, fungi and actinomycetes Regular tap samplings of a Scottish supply yielded whole animals, such as *Cyclops strenuus abyssorum*, *Chydorus sphaericus*, *Diaptomus* sp and *Rotifera*

Asellus aquaticus grips tenaciously to nodular encrustations in mains, while some *Nais* sp and some blood worms form protective tubes from organic detritus and rust particles attached to pipe walls Other strains are able to produce resting stages in order to survive unfavourable conditions According to Mr Smalls, underground supplies contain fewer species and smaller total numbers of organisms than supplies from the surface because underground water is less productive of organic matter on which the animals feed Systemic flushing has been used as a control measure, either by itself to flush out free-swimming animals, or together with chemical dosing to remove more tenacious species

Degrees by Television

THE planning committee of the Open University (which is the British Government's name for its proposed television university) has now outlined the pattern of the degrees which will form the core of the university's work when it begins in October 1970 or January 1971 Details of the courses will be left to the university staff to work out, but the basic system, which requires six credits for an ordinary degree and one year's work for each credit, has been put forward by the committee appointed six months ago under the chairmanship of Sir Peter Venables, Vice-Chancellor of the University of Birmingham (see *Nature*, **215**, 1322, 1967) No formal academic qualifications will be required for entry and the normal minimum time for a degree will be four years In exceptional circumstances, particular individuals might be allowed to qualify in a shorter time, but part-time students might well take longer than the minimum

Four broad "lines"—science, technology, social science and arts—have been set out for degrees, but the maximum flexibility will be provided so that students can take courses from each line Two credits in the first year foundation courses will normally be required before students can proceed to further study, but, after that, courses offering different depths of specialization can be followed. All credits for successfully completed courses will be of equal value, eight credits being required for an honours degree, two more than for an ordinary degree. There will probably be continuous assessment of student progress as well as examinations, and certificates will be awarded for each credit obtained. The committee considers that it will be essential to have an efficient student guidance service to advise on the limitations and wide possibilities of the courses and to recommend courses suitable to the various aptitudes and interests of individual students.

Correspondence courses will form the basis of every degree, and viewing–listening centres throughout Britain will have to supplement live broadcasting. The four foundation courses for the four degree "lines" will be broadcast in the first year of the university's life, and will need to be repeated every year to start students off. It will not be possible to broadcast all the component courses every year, but it is hoped that students will be able to obtain the broadcast material by some other means. One contact a week between student and tutor is suggested for foundation courses, but the committee stresses that the subject of contacts must be carefully examined.

The committee considers that other courses—professional, technical and refresher—should be instituted at the opening of the university, some of them with no examinations at the end. The committee adds that "shortage of transmission time of the broadcasting media should not be thought of as an impediment to putting on such courses. Other methods of making them available to potential audiences may very well have been developed by 1970 and should be used."

The university will also encourage other bodies such as local education authorities, extra-mural departments of universities and workers' education associations to organize courses as preparation for the university's own degrees. Regional officers will be appointed to coordinate local efforts.

The planning committee meets at present once a month, but working groups for "ways and means", "students and curriculum" and "constitution and organization" meet once a week for the bulk of the preparatory work. A fourth group is to be set up to consider finance and the costs of decisions that have so far been taken by the committee. With the charter of the university worked out, the constitution and organization group is likely to fade out, and further decisions will be taken by the committee as a whole. The relative merits of opening the university in October or January are at present being discussed, for there could be advantages in beginning the academic year in January and being able to continue through the summer when educational facilities are least used. In organizing local centres for study, the university hopes to pay rent for facilities that are under-used, such as television sets in schools which are not used in the evenings. Library facilities are also being discussed with the appropriate authorities. The 1966 White Paper (*A University of the Air*, HMSO, 1*s*.) stated that an "estimate of the potential audience can only be guesswork". As yet there has been little progress towards translating the guesses into hard figures, but a survey will be carried out this spring. It is expected that students will be older people rather than school leavers.

Finance has yet to be fully investigated, so no figure has yet been set for fees that students will pay. Salaries for academic staff and fees to the BBC for broadcasting will obviously take large chunks of the budget. Arrangements with the BBC have to be finally agreed, but transmission will be on BBC-2 which should, by the time the university begins, be covering at least 95 per cent of the country. The first courses are not expected to be broadcast in colour. No academic staff have been appointed yet, but the planning committee is thinking in terms of a core of full-time staff with an additional floating staff to help in the production of courses. The posts of vice-chancellor and secretary are the only two advertised so far and applications are under consideration.

Chairman for NERC

PROFESSOR V. C. WYNNE-EDWARDS, regius professor of natural history in the University of Aberdeen, is to be the new chairman of the Natural Environment Research Council in place of Sir Graham Sutton, who retires on September 1 this year. Professor Wynne-Edwards is well known for his contributions to ecology—particularly for his studies on animal populations. His book, *Animal Dispersion in Relation to Social Behaviour*, was published in 1962. A fellow of the Royal Society of Edinburgh and of the Royal Society of Canada, he has held appointments at the universities of Bristol and McGill. He has been regius professor of natural history in the University of Aberdeen since 1946, and it is understood that he will continue to hold this post.

From 1954 to 1957, Professor Wynne-Edwards was a member of the Nature Conservancy, from 1954 to 1966 he was a member of the conservancy's Committee for Scotland, and since 1964 he has been a member of the conservancy's Scientific Policy Committee. He was appointed a member of the Natural Environment Research Council when the council came into being in 1965. From 1965 to 1967 he was chairman of the council's Oceanography and Fisheries Research Grants and Training Awards Sub-Committee. He is at present a member of the council's Oceanography and Fisheries Committee and chairman of its recently formed Freshwater Research Sub-Committee.

Defence Research

THE House of Commons Select Committee on Science and Technology is now well set into its examination of defence research and development policy in Britain. In fact it has clearly been doing a good deal of work on the quiet, and showed off its progress at the first open meeting this session, when the witnesses came from the Ministry of Technology and the Ministry of Defence. Both ministries had submitted memoranda to the committee and, perhaps revealingly, both were dated October 1967, a time when the select committee had only a notional existence—according to the rules of the House, it has to be re-established at the beginning of each session.

One result of this was that the Ministry of Defence document was slightly out of date—perhaps an occupational hazard in a department which on its own admission is used to working on projects with lead times of seven to ten years. Much of the discussion was on the procedures by which the Ministry of Defence keeps a check on research projects—the so-called Gibbs–Zuckerman procedures Mr G Leitch, Deputy Under-Secretary (Equipment), said that these were designed to give pauses for thought at crucial stages of any project Less charitable observers have suggested that the procedures are laborious and time-wasting, but Mr Leitch denied this With hindsight, he said, one could say, "Well, perhaps we did waste thousands of pounds by waiting at a certain stage—but isn't this better than wasting millions later ?"

The Ministry of Technology also submitted a memorandum, parts of which bore evidence of the minister's personal touch (As well as calling the Ministry of Technology "Mintech", the memorandum goes on to call the old Ministry of Aviation by the awful title "Avmin") The memorandum explains that the majority of research contracts are let on the basis of "a carefully controlled development cost plan" It might therefore have been better if the memorandum had not gone on in the next paragraph to discuss the projects in which the United States Phantom has been refitted with Rolls-Royce Spey engines This has been a very costly project The first thing the ministry witnesses revealed was that the long promised White Paper on research policy is not now expected until "the second half of this year" (It should originally have been published by now) In part the delay was because of changes in defence requirements, and in part because of the discussions the minister was having about the future of the Atomic Energy Authority

Later, Dr G G Macfarlane, one of the three controllers of research in the ministry, produced an interesting argument Defending the role of the ministry establishments, he said that in reality the balance of research work between research establishments and industry was much the same in Britain as it was in the United States The general impression that the United States puts more research work into industry and does less in establishments was wrong, he suggested The National Aeronautics and Space Administration had large laboratories The Lincoln Laboratory at MIT, publicly supported, was almost a replica of the Royal Radar Establishment at Malvern He did say that the tendency in Britain was now to put more into industry, but this did not mean that the establishments were redundant, and he denied the suggestion by Mr B Parkyn, a member of the committee, that the establishments were needed only to test the feasibility of schemes put up by industry There was plenty of basic research to be done, and the establishments were always useful as a fire-brigade when crises arose

Although this first meeting was dull, the investigation as a whole will be a fascinating exercise The committee is likely to call, among others, Professor P M S Blackett, Sir Solly Zuckerman and Minister of Defence Mr Denis Healey To help it in the investigation, the committee has signed on two advisers, Mr Christopher Harlow, who works for Political and Economic Planning, and Mr W R Thomas, chief scientist of Elliott Automation This is a welcome move, although the way the committee set about finding its advisers was a trifle odd Mr Thomas's experience of government service at the Royal Aircraft Establishment at Farnborough may well be of particular value

Parliament in Britain

by our Parliamentary Correspondent

Radio-telescope

MRS SHIRLEY WILLIAMS could give no information about the siting of the new radio-telescope for the Jodrell Bank Observatory But she did agree that Oswestry was one of the sites considered for the telescope The sites were all within 100 miles of the Jodrell Bank radio-telescope (Written answer, March 7)

Concorde

MR HUGH JENKINS, Labour Member of Parliament for Putney, seems to be opposed to the Concorde supersonic airliner He asked the Minister of Technology if he would take steps to ensure that, when the Concorde started to operate, the noise limits at Heathrow Airport would be the same as they are at present For the Ministry of Technology, Mr Gerry Fowler agreed that this was a design aim, but hedged by saying that the noise estimates were being continually revised as development proceeded He refused to say when Concorde would make its first flight (Oral answer, March 11)

Phantom

MR TAM DALYELL tried to establish how much it has cost to fit the Phantom aircraft bought from the United States with British engines, the Rolls-Royce Spey For the Ministry of Technology, Mr Gerry Fowler said that the cost so far had been about £75 million, which included the cost of developing the engine and adapting the airframe About sixteen Phantoms out of the total order for 170 had been treated so far Mr Fowler added that they had been aware that it might be expensive, but that it had improved the performance of the aircraft, which was necessary for naval operations (Oral answer, March 11)

Defence Research

MR TAM DALYELL has also been trying to establish how much civil research work is carried out at defence establishments So far he has asked dozens of questions without receiving any very surprising answers On March 11, for instance, he asked the Minister of Technology what general policy he had for increasing the amount of civil work in progress at the ministry's defence establishments Mr Gerry Fowler said that it was not the Government's policy to build up these establishments as civil research establishments, or to seek civil work merely to keep them at their present size He seemed quite satisfied at the arrangements that had been made for getting the results of military research over to industry Mr Dalyell later had a go at the chemical and microbiological research establishments at Porton First he asked what the toxicity of CS gas, ortho chloro benzyl malano nitrile, was Mr Roy Mason, for the Ministry of Defence, said that the toxic dose for man was about 150,000 milligram minutes per cubic metre, which was 50,000 times the dose which could be tolerated by human beings, and 200,000 times the dose needed to disperse rioters No authenticated report had been received of CS causing death or injury Mr Mason also gave some information on the civil benefits of the work at Porton—protective clothing, and the study of air pollution But he refused to de-classify all future work carried out at the Porton establishments (Written answers, March 11)

NEWS AND VIEWS

Where *Escherichia coli* K12 Came From

THE chances are that one of the many mutant variations of *Escherichia coli K*12 is included in the stock culture collections of research laboratories investigating problems of bacterial genetics Mutant variations of *E coli K*12 form the basis of microbiological teaching studies in many university degree courses Yet few workers, despite their intimate knowledge of the genetical and biochemical properties of the mutant variants, know the origin and date of isolation of the original parent strain of this organism One of the first records of its use appeared in an article by C H Gray and E L Tatum called "X-ray induced Growth Factor Requirements in Bacteria" (*Proc US Nat Acad Sci*, **30**, 404, 1944) Working in the School of Biological Sciences at Stanford University, Gray and Tatum used for their study the bacterial species *E coli K*12 and *Acetobacter melanogenicum* (*M A* 6 1) The object of the experiment was to see whether it is possible to induce the formation of biochemical variants of the strains by exposure to X-rays Two such variants were isolated from the parent strain of *E coli K*12 The authors in their acknowledgments recognized their indebtedness to Dr—now Professor—C E Clifton of the Department of Bacteriology at Stanford University for providing the strain In a later paper, Tatum (*Proc US Nat Acad Sci*, **31**, 215, 1945) described the isolation of further mutant variants by a second X-ray irradiation of the two mutant strains obtained by Gray and himself in 1944 J Lederberg and Tatum, writing in *Nature* (**158**, 558, 1946), indicated that they had obtained triple mutants

The first and apparently only indication of the origin of *E coli K*12 was put forward by Tatum and Lederberg in an article entitled "Gene Recombination in the Bacterium *Escherichia coli*" (*J Bact*, **53**, 673, 1947) There the authors stated that the mutants used were obtained from a single strain of *Escherichia coli K*12 They described this organism as a "typical coliform bacterium originally isolated from human faeces—a Gram-negative rod, motile, lactose-fermenting, producing indole and susceptible to each of the *coli* phages in the series *T*1 to *T*7 of Demerec and Farro (1945)" It is also mentioned that the strain had been used for several years at Stanford University in the students' laboratory In 1960, Ida and Frits Ørskov pointed out (*Acta Path Microbiol Scand*, **48-49**, 47, 1960) that "12" was a strain number and that the letter "*K*" had nothing to do with the *K* antigen of that strain The resolution of the origin of *E coli K*12 depends, however, on Professor Clifton, whose records show that this particular strain had been isolated from the faeces of a diphtheria convalescent in 1922 and added to the stock collection at Stanford in December 1925 The place of isolation is not clear, but Professor Clifton guesses that it may have been Stanford Hospital The "*K*" is a catalogue symbol and "12" indicates that the particular strain was the twelfth culture of *E coli* that was added to the stock collection. Since 1925, the strain has remained on nutrient agar at Stanford as a stock culture for teaching and research purposes

Comparative Zoology at Harvard

THE Museum of Comparative Zoology, the Agassiz Museum at Harvard University, bristles with famous names among its staff—Professor Ernst Mayr, the director, Professor F Carpenter, Professor P J Darlington, jun, Professor B Patterson, Professor G Gaylord Simpson, Dr A Sherwood Romer, Dr W J Clench—to name a few Some of the work of these and of the other staff of the museum during 1966–67 is described in the latest annual report just published

Like many other museums of its type, the Museum of Comparative Zoology has teaching and curatorial responsibilities, expeditions are organized to build up collections, and staff travel to study collections in other museums Research conducted in the museum covers a wide range of topics—evolution, behaviour, ecology, zoogeography, physiology and biochemistry and taxonomy Almost all the research produces results of interest to the evolutionist One interesting find during the year was the discovery of a fossil insect from Cretaceous amber from New Jersey This is the oldest known ant and is apparently virtually a missing link between ants and wasps The presence of worker characteristics in these insects is evidence of the existence of social Hymenoptera as far back as about 100 million years

The discovery of several new specimens has enabled Professor Simpson to start work on the evolution of an extinct family of South American marsupials, the Argyrolagidae Until recently, it was not even certain whether these animals were marsupials Apart from the mystery surrounding their relationship, these fossils are interesting because they represent an ecological specialization unique among marsupials or any other South American mammals, and they convergently resemble the unrelated "kangaroo" rats of North America A method of food gathering unique for the bivalve molluscs and previously unrecorded was discovered by Dr Turner of the museum—she has found that the elaborately branched ciliated incurrent siphon of the shipworm *Neoteredo reynii* acts as a filter-feeding mechanism

Dr R H Chesher has adopted a new approach to his studies of the classification and variation of heart urchins (Spatangoida) As a deep-sea diver, he has taken his investigations to the sea floor itself, and he has found that some of the features hitherto used in the classification of these animals may be subject to non-genetic modification by the environment

An analysis of the ammonite fauna of the world in one subdivision of the geological time scale has been completed by Dr Bernhard Kummel. A study of all collected taxa of ammonoids for the uppermost zone of the Scythian (Lower Triassic) shows that the total fauna consists of 65 genera and 155 species. A comparison of the faunas of the Tethyan, the eastern and western Pacific, and the circum-Arctic regions shows that there is a diversity gradient, most probably reflecting a latitudinal change in climate: the faunas of the Tethyan region are rich in numbers of individuals as well as in species; the Arctic region, on the other hand, is poor both in number of specimens and in species. These results appear to support the thesis of continental and oceanic permanence for this short segment of time.

Work on thermoregulation in the beaver was completed by Dr Coles. He has been particularly concerned with the role of the tail in this regulation. Beavers are unable to lose much heat from their bodies because of their heavy fur cover; when they are exposed to heat, the naked tail is the main region of heat loss. When they are exposed to cold, however, little heat is lost from the tail because of a counter-current heat exchange system among the arteries and veins.

Long Haul

from our Correspondent in Molecular Biology

DESPITE a great deal of information which has accumulated about the function of the ribosome, it remains a largely inscrutable structure. The large number of protein components in particular gives an impression of discouraging complexity. A number of groups of workers have, however, embarked on the heroic task of fractionating the proteins of *E. coli* ribosomes and characterizing them individually. The first studies were from the laboratories of Tissières and of Moller, and the Geneva group have now reported their findings to date (Moore *et al.*, *J. Mol. Biol.*, **31**, 441, 1968).

They have begun by fractionating the extracted proteins of the 30*S* sub-unit. The evidence of gel electrophoresis and ion exchange chromatography indicates that there are twenty separate components. Of these, thirteen have been isolated in states of 80–90 per cent purity. Their molecular weights have been determined by sedimentation equilibrium, and are found to vary between about 5,500 and 28,000. The relative weights of the various components were obtained by radioactivity measurements on the ^{14}C-labelled components, separated in polyacrylamide gels. This gave the important and unambiguous result—confirming earlier surmise—that one molecule only of each ribosomal protein is present in each 30*S* particle. Moore *et al.* suggest that a true ribosomal protein should be defined as one which obeys this stoichiometry.

In order to ascertain whether common features of sequence exist in the thirteen isolated proteins, tryptic fingerprints were examined. By this criterion there are no detectable homologies. It is thus likely that these are structurally unrelated molecules controlled by different genes.

A promising approach to the study of ribosomal proteins *in situ* is described by Ostner and Hultin (*Biochim. Biophys. Acta*, **154**, 376, 1968). They have treated ribosomes (in this case from rat liver) with proteolytic enzymes, and then extracted the protein and examined it on polyacrylamide gels for fragmentation. Only some of the proteins were susceptible to proteolytic attack in the ribosome and these were degraded by all three proteolytic enzymes which were tried. The remaining proteins were highly resistant. By contrast, extracted proteins are rapidly and extensively degraded. It is concluded that the proteins are in large measure inaccessible in the ribosome. Because treatment with the enzymes brings about some dissociation of the ribosomes, it is not certain to what extent it is the separated sub-units which are attacked. It is also, of course, difficult to be certain that the enzymes contain no nuclease contaminants, though the activity of the ribosomes in respect of incorporation after appreciable exposure to the proteases gives the hope that this may not be serious.

The function of the different ribosomal proteins is another issue, and one on which some progress has been made. The identification of a new protein factor, associated with the ribosome but washed off in ammonium chloride solution, has now been reported by Brown and Doty (*Biochem. Biophys. Res. Commun.*, **30**, 284, 1968). This protein (given the arresting name of Factor 3) is required for the binding of synthetic messenger and probably also viral RNA, and its discovery is therefore an important advance. Apart from direct binding studies it was also shown that only in the presence of Factor 3 were ribosomes able to enhance RNA synthesized by DNA-dependent RNA polymerase: the freshly synthesized RNA causes product inhibition of the enzyme, and the ribosomes can act as a trapping agent for the inhibitor. Brown and Doty also quote as yet unpublished work along these lines by Gros and his collaborators.

Polarity of RNA Phages

from our Cell Biology Correspondent

AN amber mutation at the position of the codon specifying the sixth amino-acid (glutamine) in the coat protein cistron of the virtually identical RNA bacteriophages *R*17 and *f*2 has a polar effect. The mutation not only causes the termination of synthesis of the coat protein but also reduces the level of expression of the cistron which specifies the enzyme RNA synthetase. As a consequence, during single infection with the polar coat mutant there is a marked depression in the synthesis of phage double and single stranded RNA molecules and the polar coat mutant fails to complement amber mutants in the RNA synthetase cistron during mixed infections. This polarity is, however, suppressed by hosts containing strong amber suppressor genes.

The question then is what is the mechanism of polarity in RNA phages. One possibility—a purely translational model—is that the polar amber mutation in the coat cistron prevents the translation of the infecting parental RNA molecule (parental plus strand). This model predicts that, as little or no RNA synthetase is made, very few of the parental RNA molecules should be incorporated into a double stranded replicative form *in vivo* (see *Nature*, **214**, 1287, 1967). In the absence of RNA synthetase the synthesis of a complementary minus strand and then progeny plus strands is obviously blocked from the outset of infection. Alternatively, if, as Stent originally proposed, translation and transcription are coupled, the infecting RNA molecule might be translated, RNA synthetase made and a minus strand and replicative form made

Further transcription, however, of progeny plus strands from the replicative form would be blocked because translation of the nascent plus strands would be terminated by the polar mutation This less likely model requires that the infecting plus strand can be translated whereas nascent progeny plus strands cannot

Recent work by Roberts and Gussin (*J Mol Biol*, **30**, 565, 1967) and latterly Lodish (*J Mol Biol*, **32**, 47, 1968) indicates that the first, purely translational model is correct Roberts and Gussin using the polar coat mutant of R17 showed conclusively that, as predicted by the translational model, infecting RNA molecules are only poorly incorporated into a double stranded replicative form during infection of a host that lacks amber suppressor genes Lodish has shown the same for the polar coat mutant of *f*2 The level of incorporation of parental RNA molecules into a double stranded molecule is only 15–25 per cent of the wild type levels

Furthermore, Lodish has shown that the few double stranded replicative form molecules that are formed with the polar coat mutant RNA function normally as templates for synthesis of progeny plus strand RNA molecules The amber mutation does not therefore block the transcription of progeny RNA molecules from a replicative form (Gussin's 1966 delayed complementation experiments also indicate this)

To prove this, Lodish used a double mutant which has the polar coat mutation and in addition a temperature-sensitive mutation in the RNA synthetase cistron This temperature-sensitive mutation affects the RNA synthetase enzyme so that at 43° C it can synthesize plus strands but not minus strands Thus at 43° C a parental plus strand displaced from the double stranded template by the synthesis of a progeny plus strand does not serve as template for the synthesis of another minus strand At 43° C, therefore, displacement of parental plus strands which are not reincorporated into double stranded molecules becomes a sensitive measure of plus strand synthesis What Lodish found is that both wild type and double mutant RNA molecules are displaced from a double stranded template at the same rate at 43° C The polar mutation therefore has no effect on transcription of double stranded RNA The only effect of the polar mutation on RNA replication is that it depresses the incorporation of parental plus strands into a replicative form

These results, together with the demonstration of polarity in *in vitro* protein synthesizing systems programmed with polar coat mutant RNA (see *Nature*, **216**, 1070, 1967), conclusively show that at least with RNA phages polarity is a translational phenomenon

The Centriole and the Spindle

from our Cytogenetics Correspondent

TECHNIQUES for synchronizing the phases of the cell division cycle have allowed the timing of events in the cycle to be analysed in some detail Most work with synchronized cells has been concerned with events in the nucleus, but now Robbins, Jentzsch and Micali (*J Cell Biol*, **36**, 329, 1968) have studied the timing of centriole replication in a synchronized population of HeLa cells Electron microscope observations of the centriole complex at telophase and early G_1 interphase show that it consists of two orthogonally paired bodies Later in G_1 the members of the pair move apart, and as the cell enters S, each centriolar body appears to bud a replica By the end of S there are two complete centriolar complexes This coincidence of centriole replication and nuclear DNA replication suggests there may be a common control of replication because centrioles may contain DNA

A different view of centriole replication is held by Batisse (*C R Acad Sci*, **266**, 130, 1968) Strictly speaking, he observed kinetosomes (in the Suctorian *Discophrya*), but these structures are probably homologous with centrioles Batisse believes the parental kinetosome does not divide but is able to cause the condensation of precursors for a new kinetosome

In the HeLa cells, signs of centriole activity are first seen in G_2 and as the cell enters prophase In these phases the centrioles are the focus for the aggregation of electron-opaque bodies and less opaque vesicles Moreover, the cytoplasm around just one of the centrioles becomes electron-dense These changes probably represent early stages in the assembly of the mitotic spindle Later in prophase the centriolar complexes migrate to opposite ends of the cell where, at metaphase, they define the apices of the spindle

Hoskins (*Nature*, **217**, 748, 1968) recently suggested that chromosomal DNA at the kinetochore may play a part in ordering the structure of the spindle, it may be equally plausible that the DNA contained by the centriole may play a similar part in spindle organization Hoskins's diagram of kinetochore structure is very similar to electron micrographs of the kinetochore at meiotic metaphase in *Tradescantia* and *Lilium* pollen mother cells, published respectively by Wilson (*Planta*, **78**, 379, 1968) and Dietrich (*C R Acad Sci*, **266**, 579, 1968) In both cases the kinetochore is large, less electron-opaque than the rest of the chromosome and serves as an attachment point for spindle fibres These observations may imply that DNA has another function besides genetic coding, namely, serving as a site for the assembly of protein sub-units for the spindle

Improving Crops

AGRICULTURE is going to have to play an even more important part in the economy of most countries, and plant breeding has a great deal to offer, as it has done in the past twenty years This was the starting point taken by Dr G D H Bell, director of the Plant Breeding Institute in Cambridge, when he gave a review lecture at the Royal Society on March 7 His topic was "Plant Breeding for Crop Improvement in Britain Methods, Achievements, and Objectives"

Among the cereals, since 1946–47 the yield of wheat has increased from 19 to 31 2 cwt/acre, that of barley has increased from 17 8 to 28·7 cwt/acre and that of oats has increased from 16 3 to 24 4 cwt/acre During this time, many new varieties have been developed for commercial use, incorporating higher yields, better straw, and earlier ripening Improvements in barley were made possible by hybridization of British varieties with Scandinavian varieties A spring barley that proved particularly successful was Proctor, which shows a good yield, field resistance to some diseases, and high malting quality Winter malting barleys such as Pioneer and more recently Maris Otter have been developed by hybridization Higher yielding varieties than Proctor are now available, but the chief problem is combating leaf disease, particularly mildew Some of the new varieties have resistance to one or two races of the fungus, but non-specific resistance must be exploited if stability is to be attained.

Resistance to disease in wheat, especially to yellow rust, is also a major concern, while raising the yield and maintaining the baking quality are also important. A useful breeding variety called Compair has recently been produced by introducing a chromosome into hexaploid wheat by crossing with two species of *Aegilops*. This shows resistance to all known strains of yellow rust. The yield of both winter and spring wheat has increased considerably and there are new varieties, such as Maris Ranger, which give 8 per cent higher yield than the standard varieties of the past fifteen years. Maris Widgeon, a winter wheat, and Troll, a spring wheat, are two with a high baking quality. The yield potential of wheat is undoubtedly increasing, and new hybrids are indicating even higher yields, although not combined with good baking quality.

Continued improvement will depend on a more intensive use of more refined techniques and a closer integration of genetics, physiology and pathology. New models are being formulated both morphologically and physiologically and wider genetic variation is being used. Dwarf wheats and barleys are being developed with higher ratios of grain to straw and good yields, while huskless oats with good field characters are also an important objective. Physiological research in the field is showing differences between varieties on which breeding work can be based.

Dr Bell also showed how breeding work has made its contribution with potatoes and sugar beet. The biggest breakthrough with potatoes has been the recent increase in higher yielding main crop varieties such as Maris Piper and Pentland Dell. Maris Piper also shows resistance to one form of eel worm. Quality for processing—chips, crisps and so on—is also of increasing importance. In the case of sugar beet it is less easy to distinguish the advances in yield due to breeding from those due to cultivation. The development of monogerm and bolting-resistant varieties, however, is most significant for efficient husbandry, while polyploidy should make possible improvements in sugar production with better combinations of root yield and sugar percentage. For the greatest expression of yield, diseases such as virus yellows must be controlled, if possible by breeding. The production of Maris Vanguard, a virus-tolerant variety, is important in this respect.

Climate Control

RUSSIAN scientists have made significant advances in climate control, judging by the bibliography *Weather Modification in the Soviet Union, 1946–66*, published by the US Library of Congress in Washington. The Russians seem to have become particularly adept at cloud dispersion—in November 1953 they cleared clouds from an area of 2,500 square kilometres for a parade in Moscow, and in February 1961 a continuous cloud cover over the Crimea was broken in certain places to permit observations of a total eclipse of the Sun. The new bibliography provides an almost complete coverage of Soviet publications on weather modification received by the Library of Congress between the years 1961 and 1966.

The Russians are having some success with fog dispersal. In the winters of 1964 and 1965 fog dispersal methods were applied at 12 airports, making regular flights possible. Noticeable economic effects are claimed for this work. Hail suppression also receives considerable attention in the Soviet Union, especially in meteorological institutions in the Transcaucasus where hailstorms frequently cause serious damage.

The bibliography lists entries under seven headings, and includes tables summarizing Soviet experiments in weather modification. It is available from the US Government Printing Office, Washington, at 55 cents.

Penta-Coordination

from a Correspondent

CHEMISTRY will lose much of its interest if the time arrives when the shapes of molecules and relative—or even absolute—bond lengths can be predicted. A discussion on penta-coordination, arranged by the Chemical Crystallography Group of the Chemical Society on March 5, showed that we are a long way from reaching this state for compounds in which one atom is surrounded by five entities.

In the opening lecture, Professor H M Powell reviewed the problems of defining, for example, whether a lone pair of electrons constitutes a coordinating entity. Many compounds with empirical formulae consistent with penta-coordination crystallize so that the actual coordination is six or more. Where penta-coordination is established, two regular geometries are found, the trigonal bipyramid, favoured by non-transition elements, and the tetragonal pyramid. The latter geometry is found for later transition metals where it is favoured by ligand field stabilization energy, for example, a tetradentate tertiary arsine ligand (TTS) adopts a sterically strained configuration round Pd in Pd TTS Cl to give this geometry, although a trigonal bipyramid would require less strain.

A careful study of Cu(II) complexes with α-hydroxy carboxylate anions by Drs J R Carruthers, C K. Prout and F J C Rossotti established that the structure determining feature in the solid state was the formation of strong hydrogen bonds between the hydroxyl groups of one anion and the keto oxygen of another. This might result in five or six coordination for the copper, with or without the presence of coordinated molecules of water. For this ion, at least, ligand field effects are apparently weaker than hydrogen bonding and other inter-molecular interactions in the crystals. Factors affecting choice of coordination number were also considered by Dr J M Pratt. Stability constant measurements on the replacement or removal of water from the "sixth" position of metal-corrin-X-H_2O systems showed that this was favoured as the electron donor properties of the ligand X increased, six, five and four coordination were preferred by Fe(II), Co(II) and Ni(II) respectively.

Early transition elements form trigonal bipyramidal complexes. Dr J S Wood discussed three of these, correlating the magnetic properties with distortions from 120° in bond angles in terms of ligand field effects. Professor J W Linnett considered possible electronic structures of penta-coordinate non-transition elements, with particular emphasis on the need to explain relative bond lengths, for example, the short axial bond in BrF_5.

There was a wide ranging discussion opened by

Professor G W A Fowles, both he and Dr F G Mann gave examples of apparently inexplicable differences in behaviour on dissolution of similar complexes Dr P Pauling told a cautionary tale about a Ni(II) complex which crystal structure analysis has established as penta-coordinated by one chelate and one tridentate tertiary arsine

Use of Blood Grouping

ON March 6 the second public lecture was held at the Natural History Museum in memory of the late Sir Ronald Fisher, who made many important contributions to both genetics and statistics The lecture—"Blood Groups in Human Genetics"—was delivered to the large audience by Dr R. R Race of the Medical Research Council Blood Group Research Unit, who is well known for his work on blood groups

Sir Ronald realized that blood groups could be a useful tool for the improvement of knowledge in human genetics, especially for the mapping of genes on the chromosome From the bewildering reactions of the various Rh antisera, he saw the simple pattern of a controlling system of three very closely linked loci each with alleles. These loci were assumed to be so close together that crossing over between them could be only an extremely rare event The only way in which this concept has been modified in more recent times is that the three loci are regarded as being in one cistron, with a number of mutational sites for each of the loci *C*, *D* and *E* As postulated by Sir Ronald, the order of these sites is *DCE*.

Sir Ronald also applied mathematical tests to autosomal linkage groups In the early days of blood groups, few marker characters were available, but since then at least eight have been found, and the estimated distances between the pairs of loci range from about 1 to 22 cross-over units (centimorgans) The next step will be to find on which autosomes the loci are located, the most hopeful development in this direction so far has come from Paris, where a boy was found to have an abnormal Hageman factor or factor XII—responsible for a prolonged blood coagulation time It seems that the locus for this factor is on the upper part of the short arm of autosome No. 6

Chromosome mapping may also contribute to an understanding of testicular feminization, a rare and interesting condition People with this condition not only pass as females but tend to be particularly attractive ones, even though their chromosome counts show that they are cytological males It was hoped that the sex chromosome-linked blood group Xg might throw some light on this problem, but these hopes have not yet been realized

Blood grouping has also contributed to the study of twin chimerism, a rare condition in which dissimilar twins have been reported to have two types of blood each It may also be used to study dispermy, which results from the penetration of one ovum by two sperms Human examples are mosaics, often for sex, usually for blood groups and perhaps for eye and skin colour It is thought that one sperm probably fertilizes the egg nucleus, and the other may perhaps fertilize the nucleus of the second polar body, but this is not known for certain The results of testing many father–mother dispermy sets for the blood groups and other markers may in the future allow some estimate to be made of the identity of the two female nuclei which have been fertilized

Antioxidant Metabolism

from our Medical Biochemistry Correspondent

DRUGS and food additives are all tested in laboratory animals before they are ever administered to human beings It is often assumed that enzyme reactions are universal, and species differences are negligible to the biochemist A recent paper on the metabolism of 3,5-di-*tert*-butyl-4-hydroxytoluene (BHT) in the rat and in man illustrates how great interspecies differences can be (*Biochem J*, **106**, 783, 1968)

BHT is widely used in food as an antioxidant in fats Very different rates of excretion have been found in man and in the rat In man, half of any dose appears in the urine within the first twenty-four hours, but in the rat there is evidence suggesting that metabolites are retained in a circulation between the intestine and liver by excretion in the bile, reabsorption from the small intestine and transportation to the liver ^{14}C-labelled BHT was given orally in olive oil to laboratory rats, and in gelatine capsules to two male human subjects Urine, faeces and bile were collected from the rats, and urine from the two humans The radioactive metabolites were separated by extraction followed by chromatography, and identified by ultraviolet, infrared, nuclear magnetic resonance and mass spectroscopy.

In the rat, most of the activity in the urine was in 3,5-di-*tert*-butyl-4-hydrobenzoic acid (BHT acid), a glucuronic acid conjugate of BHT acid and a mercapturic acid S-3,5-di-*tert*-butyl-4-hydroxybenzyl-N-acetyl cysteine There was some evidence suggesting that the mercapturic acid was formed by a non-enzymic reaction between cysteine and BHT free radical and not by any of the known enzyme systems By contrast, the human urines contained one major labelled product This was an ether insoluble glucuronide in which the BHT residue had carboxyl groups replacing the ring methyl and one tertiary butyl methyl group, while another tertiary butyl methyl group appeared to be oxidized to an aldehyde group BHT acid and its glucuronide were found in only small quantities in human urine, and there was practically none of the mercapturic acid found in large quantities in rat urine.

The mercapturic acid and BHT glucuronide were found in large quantities in rat bile, and must have been the compounds circulating between the small intestine and liver in the rat Since these compounds were only formed in very small amounts in man, this could account for the absence of an enterohepatic circulation in man. The main component in rat faeces was BHT acid, which was presumably excreted in the bile and not reabsorbed in the intestine

The authors point out that these results do not show whether the pharmacological effects of BHT in the rat and man are likely to be similar or different. Where such large differences exist in the detoxification reactions undergone by a compound in two different species, however, it is unsafe to assume that effects observed in the rat will be repeatable in man. With any substance which is likely to be used in considerable quantities by human beings, results like these indicate that there is no substitute for careful studies in man before a compound is released for mass consumption, however reassuring animal studies may have been

All Change at Cal?

by

NICHOLAS WADE

The University of California has had a longer history of crises than most universities, and it has now produced an attempt to resolve its problems which merits the attention and admiration of all concerned with the politics of academic life. The student strikes of November 1966 prompted the Berkeley division of the university's Academic Senate and the Student Senate to set up a joint study commission, composed equally of faculty members and students, to examine the university's problems and propose solutions for them. In ninety-two pages of lapidary prose in which high ideals and legal niceties are given equal attention, the study commission has now produced its report (*The Culture of the University: Governance and Education*). The report is in three parts—a diagnosis of the need for reform, the changes in practice that are required, and the steps that should be taken to effect these changes.

The commission begins its diagnosis of the university's malaise by pointing to the high rate of disaffection and disinterest among students. Only half those who enter Berkeley as freshmen receive degrees, and the drop-outs include many of the most promising students. One reason for this is that "some of our most thoughtful students have come to repudiate many of the social goals and values they are asked to serve in the university and on graduation. . . . The new world emerging seems to exact greater conformity, more routinized lives, more formalized relationships among individuals, and a deeper sense of helplessness amidst an increasingly abstract world devoid of human values". It is little wonder, the commission considers, that students no longer wish to be groomed in the "knowledge industry" to take their place in such a society, especially when the university's atmosphere has come to reproduce the bureaucratic and dehumanized characteristics of that society.

How has this come to be? The demands of external interests—economic lures, the rewards of prestige and now a hostile state administration—have increasingly dominated the ethos of the university and shaped the direction of its educational activities. In the face of these events the university has made two crucial failures—"its failure to develop a student body which respects the value of the intellect itself, and its failure to order its activities according to a conscious conception of its unique purpose of nurturing that intellect".

In diagnosing the consequence of these failures, the commission deplores the incongruity that an institution devoted to the ideals of free enquiry and discussion can be content to manage its own affairs so differently. By doing so, it loses an important educational opportunity. "Campus governance is not simply a method for arriving at decisions about educational policies, it is itself a method of educating those who participate in it." The commission rejects the assumption, implicit in its own terms of reference, that separate spheres of interest should be defined for the administration, faculty and students. It considers it pernicious to suppose that campus society is composed of three such status-bound interest groups whose conflicts can or should be settled by procedures appropriate to national politics. Most issues of university policy require qualitative judgments rooted in values and principles, and should not be decided on the basis of which group has the most bargaining power. The belief that such procedures can solve the university's problems will merely perpetuate the continuous crises of the past, its inevitable result has been "an endless process in which both sides lose, a true minus–minus game in which the game itself becomes the focus while the main purpose of the community, namely education, suffers".

The commission declines to blame any particular group in the university for past troubles, because such a diagnosis would be purely superficial. "The sources of our conflicts are very deep. They lie . . . in the numerous functions, over and above teaching, which the university has acquired or had thrust on it, in the failure of the State of California to give adequate support to education, which has weighted the university in the direction of an impersonal educational environment of large classes and anonymous relationships among and between students, and faculty, in the extreme vulnerability of the campus to outside political pressures, and in the concept of education which—tailored as it is to the demands of a society devoted to economic growth, technological advance, and increased international influence and dominion—has ceased to nourish the best aspirations of the contemporary student and faculty member."

The problem as the commission sees it is to find ways of avoiding the "blunt, non-educational methods of agonistic politics" and to set up new institutions which will resolve conflicts "in accordance with our fundamental educational objectives". A major failing of the present institutions is that they are too large, their dimensions "run counter to genuine and direct participation, discussion and resolution of issues". Dealt with at centralized levels, problems appear abstract and remote and participants lack the experience necessary for genuine discussion. The consequence of centralized authority has been that "only a few can play an active role, while the many are passive spectators whose lethargy is periodically disturbed by a superficial form of participation, namely voting". The remedy for this state of affairs is the delegation of authority to smaller units which are "commensurable with human possibilities" and in which "student–faculty–administration consultation and participation are natural forms of activity rather than contrived formalities".

To what extent is decentralization desirable and possible? The commission points out that the Byrne Report of 1965, appointed by the Board of Regents itself, recommended "drastic devolution and greater local autonomy, but its proposals have been allowed to languish". Too much power has been allowed to reside with the administration, which in consequence has been "badly skewed by repeated confrontations with dissident students and near-confrontations with the faculty". The Academic Senate also has suffered from centralization, the paucity of administrative expertise among its members has led to "a marked tendency for a relatively small number of faculty members to monopolize the membership of the most powerful committees. . . . This situation has contributed significantly to the fact that over the years the Senate has been relatively ineffectual as a vehicle for promoting educational change or stimulating discussion of the fundamental purposes of the university". As to the role of the students, the commission considers that to present them with the trappings of government has not only caused resentment and disillusion, but has "aggravated the tendency to cast students and administration in the roles of contending interest groups". A separate student government is a "non-concept", wholly inapplicable to the university situation. The right solution is to devise "a variety of institutional means through which students can be incorporated into the decision-making process, rather than confined to haggling over the extent of peripheral powers delegated to a separate organization".

From its survey of the present state of affairs the commission draws three main conclusions. The first is that "highly centralized administrative authority has ceased to command much enthusiasm on this or any other comparable campus". The second conclusion is that voluntary compliance with university rules and policy can only be secured by "actions which command respect by the standards appropriate to a university". Third, the accumulated legacy of disloyalty and mistrust "must be dispelled by building new habits of co-operation between students and administrators, as well as between faculty and administrators, so that the administration does not remain politically isolated from the campus community".

In the second part of its report the commission turns its attentions to the ways in which new patterns of co-operation can be built up. The principal requirements for such change are these, that open discussion should precede policy decisions, that there should be substantial decentralization both at state and at campus levels, and that the students' role in governance should be significantly enlarged. The case for open discussion is so strong as to verge on the platitudinous. No group, the commission opines, has a monopoly of wisdom. On several occasions in the past, administrative decisions have been announced without prior consultation and been revoked after student protests. Discussion of an issue after the event occurs in a less cooperative atmosphere than discussion before it. The commission therefore recommends that the processes of policy making should be opened up by instituting public hearings, the public questioning of officials and improved access to university documents.

The case for decentralization is equally strong. In reference to the Regents' decision in December 1966 to suspend any member of the university who participated in a strike, the commission comments that "problems which are extremely complex when seen in their specific context give the illusion of being easily solvable when seen from a Regental distance". The proper function for the Board of Regents is to allow the individual campuses of the university to manage their budgets and their affairs as they think best, and for its own part to resist any attempts by the state government or legislature to interfere. Not only should authority be delegated, but the university should be divided into smaller units. It is difficult to decide at what point a department becomes so large that it is impossible to "speak any longer of its common culture", but the commission suggests a maximum strength of 20 to 30 faculty members, 200 undergraduates and 75 graduate students.

Turning to the question of student participation, the commission rejects any analogy to natural democracy or the right of each member of the university society to have an equal vote in its affairs. But it also rejects the university's claim to stand *in loco parentis* and that of "the minority of parents who wish it to perpetuate its own supervisory role". Pettifogging rules are inconsistent with students' dignity and increasing maturity, nor is it immediately obvious why young people at university should be treated differently than their contemporaries elsewhere. "Such paternalism is anachronistic and should be forthrightly disavowed."

The commission submits definite proposals for increasing student participation, the chief of which is the appointment of students by a student board to the various committees and boards which govern the university. It concludes its report with a list of the basic regulations which it considers should govern the enactment and enforcement of campus rules.

One of the major themes of the commission's argument is perhaps summarized by a paragraph in the final appendix to the report.

"The more opportunities that exist—at all levels of university governance—for students to take active roles, the easier it will be to attract, recognize and utilize the services of promising students. The greater the range of significant and challenging policy questions which engage the student government, the higher the calibre of students likely to volunteer their services becomes."

Human Influence upon Vegetational History in North Cardiganshire

by
PETER D. MOORE
Department of Botany,
King's College,
University of London

Pollen analytical investigations at Borth Bog and upon the upland blanket peats of Cardiganshire have elucidated the role of man as a factor influencing the development and destruction of the vegetation of the area. The times of the most severe forest destruction appear to have been the Iron Age/Roman period and the fourteenth to eighteenth centuries.

The application of the technique of pollen analysis to the elucidation of problems relating to the influence of man on vegetation is now fairly well established[1,2], but, despite this, detailed analyses coupled with a correlation of pollen and archaeological data for an area are still few. In this article the results of some investigations in the northern part of Cardiganshire will be described and a tentative correlation between these data and local archaeological and historical evidence will be suggested.

For the sake of brevity, only two sites will be considered. Several other sites were studied and the results obtained from these will be published in greater detail elsewhere.

The first site to be considered here is Borth Bog. This is an extensive raised bog on the southern side of the Dovey estuary, which has recently been acquired by the Nature Conservancy as a Nature Reserve. Pollen analysis has been carried out at this site by Godwin[3], but only the figures for the tree pollen have been published. The site selected for the present work was in the north-eastern part of the bog, the results of pollen analysis are shown in Fig. 1 and Fig. 2.

The stratigraphy at this point shows that the bog developed on a stiff blue clay. *Phragmites* reed swamp was the first vegetation, followed by trees, first alder, then birch and finally pine. At other sites on the bog the tree layer is more pronounced. It is this layer which extends beneath the shingle beach at Ynyslas and is there exposed by tidal action[4]. Above this there is a fibrous peat containing the remains of *Eriophorum vaginatum* and above this is a considerable depth of *Sphagnum imbricatum* peat.

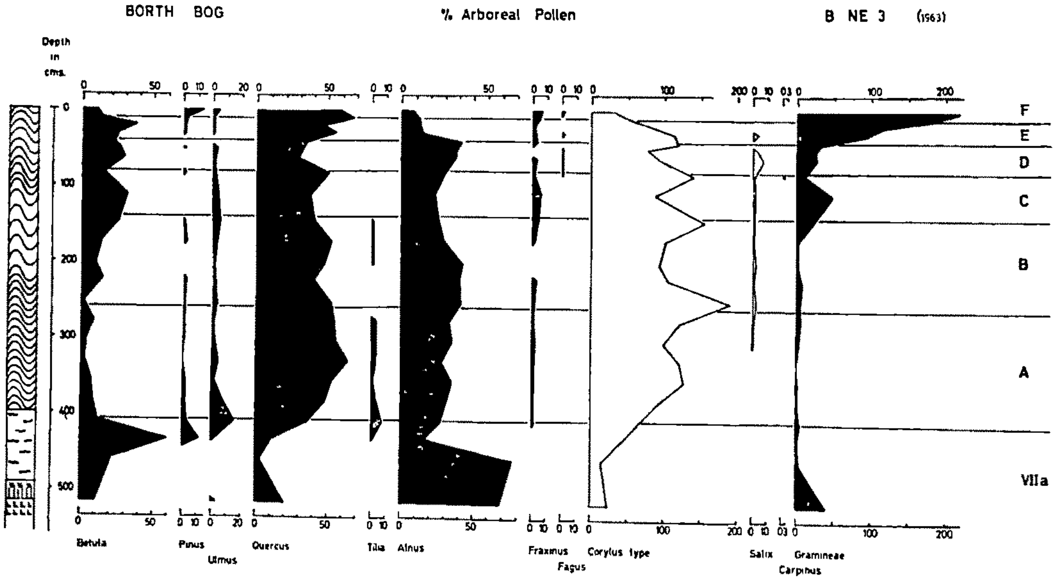

Fig. 1.

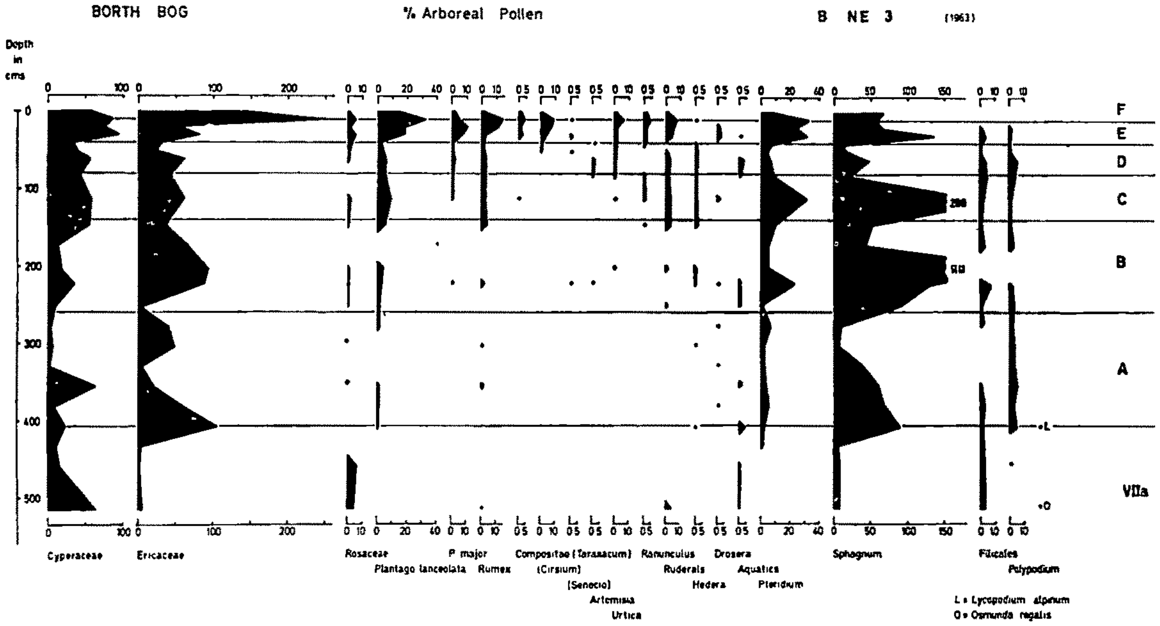

Fig 2.

Figs 1 and 2 Pollen diagrams from Borth Bog, Cardiganshire The zones *A–F* are considered to be of local significance only and represent stages in the development of the vegetation of the area under varying degrees of interference by man

The tree pollen curves at the base of the profile appear to reflect the local succession of trees on the site, but, with the disappearance of woodland in the immediate locality as a result of ombrogenous bog formation, the pollen curves may be regarded as representing more widespread changes in vegetation

For the sake of convenience, the upper part of the diagram has been divided up into zones *A–F* These are considered to be of local significance only They are characterized by the following features

A A decline occurs in the pollen of *Ulmus*, elm, together with the first appearance in quantity of *Plantago lanceolata*, ribwort plantain, and *Pteridium aquilinum*, bracken These are species which are frequently associated with woodland clearance and grazing by domesticated animals, and the fall in elm pollen suggests that this was a species particularly affected by such clearance Human activity, however, may have been of limited extent, for weed pollen does not attain very large proportions in this period

B Increases occur in *Plantago* and in *Pteridium* during this period, particularly at a depth of 200–220 cm. This implies that the influence of man on surrounding vegetation was becoming more severe Pollen of *Betula*, birch, increases during this period, possibly as a result of the invasion by birch of abandoned clearings

C During this period there is yet further evidence of increased human activity Not only do the weed species already mentioned increase, but also numerous other weeds, including *Rumex*, sorrel, become more abundant At the same time both *Alnus*, alder, and *Quercus*, oak, pollen curves suffer a decline, while *Betula* and *Fraxinus*,

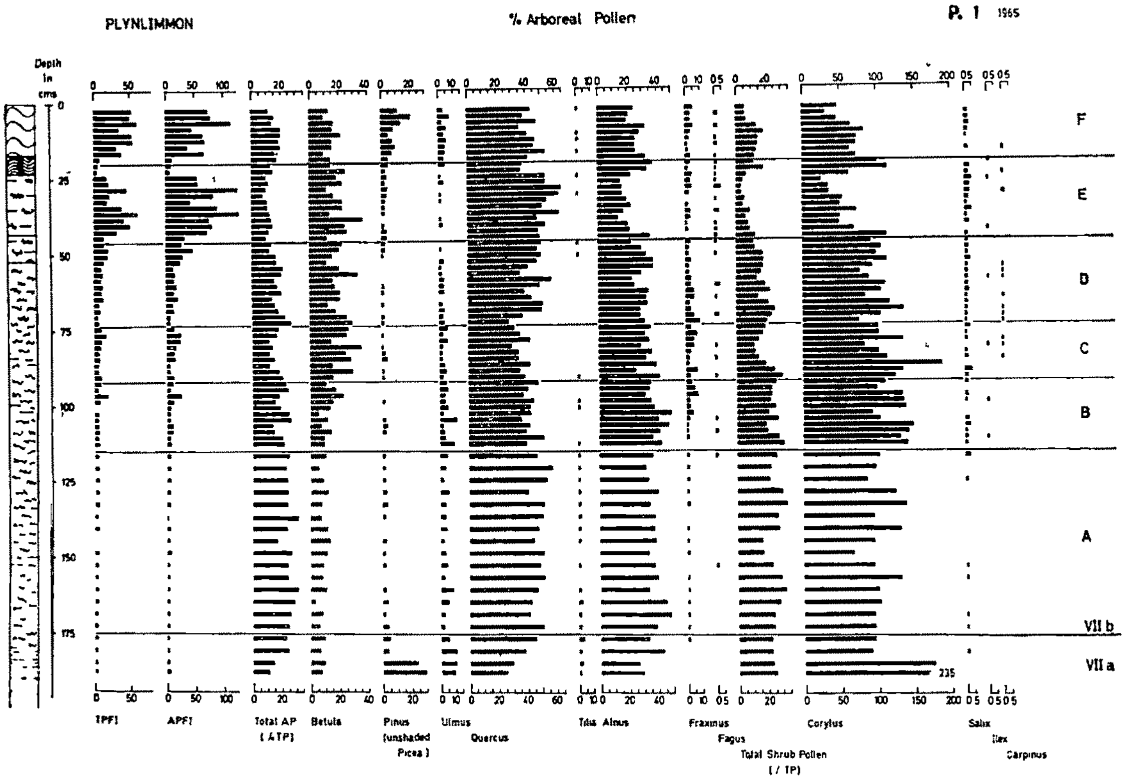

Fig 3

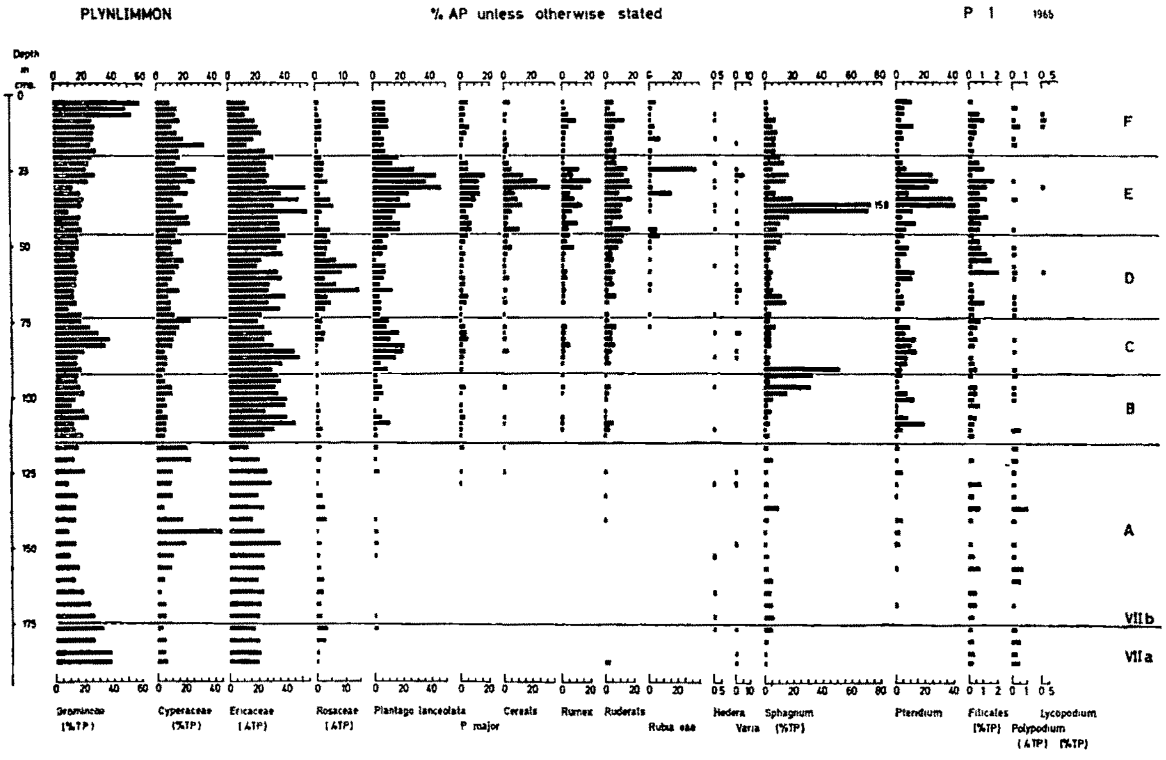

Fig 4

Figs 3 and 4 Pollen diagrams from Plynlimmon, Cardiganshire The zones A–F are thought to correspond to the equivalent zones of the Borth Bog diagrams ash, both trees preferring relatively unshaded habitats, increase Grass pollen becomes more abundant during this period, which, together with *Plantago lanceolata* could indicate a pastoral economy among the local peoples

D. Following the period of intensive clearance there is a period during which some recovery of trees appears to have taken place Alder in particular increases, while many of the weeds and *Pteridium* decrease Evidently the activity of man lessened during this period

E In this period, all weed species increase very rapidly to attain their highest values At the same time there is a marked drop in alder pollen There is some evidence from the *Plantago lanceolata* and *Pteridium* curves to suggest that this intensification of forest clearance and agricultural activity occurred in two phases, separated by a temporary lull It was during the second of these phases that weeds typical of arable farming reached their greatest prominence

F. Following the period of activity there comes an equally sudden decline in many weed species Grass pollen, however, continues to increase in abundance *Pinus* pollen (there are included here some grains of the genus *Picea*, spruce) also increases in period *F* up to the surface of the bog

In many of the upland sites which I examined a very similar pattern emerged, although there was some local variation in detail By means of closer sampling techniques a more detailed account of this pattern was built up from a blanket peat site near the summit of Plynlimmon, at an altitude of 1,850 ft (607 m) The zonation system is the same as that used for the Borth Bog diagram

A few of the more obvious differences are worthy of note At Plynlimmon alder appears to suffer less in relation to oak during periods *C* and *E* It is likely that woodland on the coastal plain and in the foothill valleys was richer in alder than the upland woods Clearance of these lowland woods could result in a proportionately greater decrease in alder pollen, which would be most noticeable in the lowlands, as at Borth Bog The curve for Gramineae at Plynlimmon behaves in quite a different way from the one at Borth, because species of this family were present in the peat-forming vegetation at the upland site Cereal pollen grains are plotted separately from Gramineae at the Plynlimmon site, and reach their greatest abundance in the latter part of period *E*

In order to interpret these data in the context of changing human culture and agricultural activity, it is helpful to have a means of dating certain horizons Radiocarbon dating was not available for this study, and I had to use datable archaeological artefacts For this purpose two peat sites were chosen in which such artefacts occurred In the first, Blaen yr Esgair, a Roman road of A D 78–80 interrupted peat deposition and, in the other, at Llyn Gynon, an early medieval trackway occurred Peat from above and below these structures was analysed At Blaen yr Esgair it was found that the entire period *C* was absent from the diagram, being replaced by the Roman road At Llyn Gynon period *C* and at least some of period *E* were present

With the aid of these data, certain tentative conclusions can be drawn regarding the correlation of vegetational change with archaeological and historical records

A Initial colonization of the region was probably by Neolithic people, whose population was probably very small (no megalithic tombs are known from the immediate area[5]) Their influence on the vegetation was likely to have been small, as is evidenced by the pollen data The one exception is that of elm, which suffered a decline at this time That this was an anthropogenic phenomenon is by no means certain[6], but in all the Cardiganshire sites it was found in association with weed pollen

B The more intensive forest clearance in this zone may be a consequence of the activity of Bronze Age peoples who occupied the uplands of Cardiganshire The Plynlimmon diagram shows evidence of minor clearance episodes, followed by periods of regeneration. This type of shifting culture is in agreement with what is known of the habits of these people, who were probably nomadic pastoralists[7].

C With the coming of Iron Age culture to this region, it is likely that there was a movement of population from the uplands to the foothills and the coastal plain[8] These people, together with the Romans, who invaded Wales between A D 43 and 78, were probably responsible for the considerable destruction of forest which evidently occurred during this period Some forest destruction could have resulted from the fighting which ensued and from the building of roads, but it is likely that an increase in pastoral farming under the *pax Romana* was the most important factor resulting in forest clearance.

D There follows a period of less intense activity and some forest regeneration The withdrawal of Roman legions, probably completed by A D 400, led to times of tribal warfare, which continued throughout much of the Dark Ages As a result, agriculture became once again a rather unstable activity Not until the Monastic period, beginning in Cardiganshire with the founding of Strata Florida Abbey in the south, did this state of affairs change

E The Strata Florida estate covered a large proportion of the uplands of Cardiganshire and supported large numbers of sheep This organized pastoral farming may well have resulted in the renewed forest destruction which occurred during period *E* The direct intervention of Edward I in 1280 could have been of considerable importance for Welsh vegetation, for he sent orders to various officers in Cardiganshire commanding that all woodland should be cleared so that it might not harbour thieves and rebels, with whom he was experiencing considerable difficulties It is quite possible that much of the lowland and valley woods, rich in alder, were cleared at this time, resulting in the marked decrease in alder pollen during period *E*

As has been mentioned, there seems to have been a pause in the destruction of forest during this period, which could have resulted from the reduction of the population of Cardiganshire in the fifteenth century following the Black Death and rebellion against Henry IV

Subsequently forest destruction continued as the cattle breeding industry grew in importance and as the uplands were enclosed The process reached its climax during the Napoleonic Wars, when cereals were grown even at high altitudes, hence the abundance of cereal pollen at Plynlimmon in this period The coming of peace in 1815 resulted in depression and mass emigration, which in turn led to the abandonment of upland holdings

F Depopulation continued throughout the nineteenth century and there is some evidence for the recovery of woodland, particularly in the uplands Added to this there was an increased interest in afforestation by some of the local inhabitants These interests were finally taken up by the Forestry Commission, resulting in the increase in *Pinus* and *Picea* pollen found in period *F*

I thank Mr E H Chater for his supervision of this work and also Dr D D Bartley for help with the techniques of pollen analysis This work was carried out at the Department of Botany, University College of Wales, Aberystwyth, during the tenure of a Science Research Council studentship

Geochemical Reconnaisance and Hypocuprosis

by

J S. WEBB

University of London

Regional geochemical reconnaissance in the Southern Pennines can aid the detecting and mapping of the incidence of hypocuprosis—a trace element disorder of agricultural importance.

GEOCHEMICAL reconnaissance by stream sediment sampling was first developed systematically for purposes of mineral exploration in 1952 Subsequently, it has been shown that by using appropriate methods of analysis and interpretation, trace element patterns detected in the active sediments reflect in varying degree the distribution of the elements in the rocks and soils as a whole[1,2] Preliminary studies of the application of this technique to agricultural problems in the Irish Republic and the United Kingdom showed an encouraging degree of correlation between the regional distribution of molybdenum, selenium and cobalt in stream sediments and the incidence in livestock of molybdenosis, selenosis and cobalt "pine", respectively[3,4]. Subsequent geochemical and agricultural reconnaissance of some 3,000 square miles in parts of Devon, North Wales and the southern Pennines has demonstrated a number of similar correlations between the trace element patterns and agricultural disorders The following description is concerned with one aspect of these current studies, namely, the distribution of molybdenum and associated elements in relation to hypocuprosis in cattle in parts of Derbyshire and North Staffordshire

The Study Area

The reconnaissance covered 900 square miles in the rectangle between Stockport, Sheffield, Derby and Stoke-on-Trent (Fig 1) Grossly simplified, the geological structure is that of a dome elongated along an N-S axis and slightly tilted to the east The outcrop of the Lower Carboniferous Limestone dominates the centre of the area and is surrounded by successively younger Carboniferous rocks of Namurian and Westphalian age In the Namurian, a series of basal marine shales is overlain successively by the main Namurian sandstones and the interbedded sandstones and shales of the Westphalian sequence In places, a shale facies of the Carboniferous Limestone separates the Namurian shales from the limestone proper The Carboniferous Limestone shales are lithologically indistinguishable from the Namurian shales with which they have been grouped in Fig 1 In the south, the Carboniferous is overlain unconformably by Permo-Triassic sandstones, isolated outliers of which indicate their former extensive cover

Thick Newer Drift of the Weichsel glaciation covers the Cheshire Plain to the west but thins eastwards to terminate along the 1,250 ft contour on the western slopes of the Staffordshire hills[5] East of this line there are sporadic relics of older Pennine glaciations and periglacial deposits, but, apart from these and loessial deposits on the limestone[6], the soils are essentially residual South of the limestone, however, patches of Pennine drift are mixed with surficial remnants of Permo-Trias, though many of the valleys are drift-free

The limestone outcrop forms a well developed undulating plateau with steep marginal slopes To the north and east, valleys cut in the flanking shales lie between the limestone plateau and the scarps of Millstone Grit West and south, the Namurian rocks give rise to hilly country overlooking the undulating lowland on the Trias

Drainage is predominantly south and east into the Trent basin With the exception of the limestone plateau, the density of tributary streams is sufficient for stream sediment reconnaissance

Stream Sediment Reconnaissance

More than 600 samples of active sediment were collected from tributary streams at a mean density of one sample per square mile, except on the limestone where there is virtually no surface drainage system The unground minus 80-mesh fraction was analysed spectrographically for fifteen elements including molybdenum[7] Arsenic and zinc were determined colorimetrically[8,9]

Anomalous concentrations of 4–40 p p m. of molybdenum were detected in streams draining parts of the lower Namurian shales compared with < 4 p p m elsewhere (Fig 2) North and east of the limestone the anomalies are confined to a narrow zone corresponding to the outcrop of these shales Widening of the shale outcrop to the south and west is accompanied by correspondingly more extensive patterns in the stream sediments, referred to as the Ashbourne and Onecote anomalies, respectively The fact that streams draining comparable shales west and north-west of the Onecote area do not show anomalous contents of molybdenum is almost certainly a result of the increasing persistence of barren drift cover in these directions and the proportion of arenaceous horizons, which are also more prevalent in the shale formation south of Onecote

Similar stream sediment patterns also associated with the Namurian shales were detected for arsenic, nickel, vanadium, chromium, cobalt, titanium and iron Copper and zinc also follow molybdenum, but the pattern is complicated by contamination from old base metal mines around the periphery of the limestone Apart, however, from arsenic, none of these metals gives the high contrast between anomaly and background shown by molybdenum A selection of molybdeniferous samples was also found to carry abnormal concentrations of selenium[10], but here, too, the contrast is usually low

Geochemical Significance of Patterns

Analysis of rock samples shows conclusively that marine facies of the Namurian shales with up to 50 p p m of molybdenum are the predominant source of this element in the area Elsewhere in the succession, shales usually contain < 5 p p m of molybdenum as do the more important arenaceous and calcareous facies (Table 1)

Reconnaissance soil traverses across the two main anomalous areas disclosed zones rich in molybdenum in the overburden above parts of the Lower Namurian succession In the Onecote area, the predominantly gleyed soils are mostly developed on residual parent material Over the shale the topsoil contains 4–35 p p m of molybdenum compared with less than 4 p p m over other rocks (Table 2) Apart from areas of moorland peaty soils where leaching may have been intense, the molybdenum content of the topsoil is largely dependent on the nature of the bedrock

In the Ashbourne area, on the other hand, the higher

ground between streams is commonly covered by barren drift In these circumstances, the Namurian shales are associated with molybdeniferous soils only in drift-free areas mostly in the valleys and on the lower slopes of the hills

In both areas, soils developed on alluvium flanking anomalous streams are also molybdeniferous Considerable tracts of such soils occur in the valleys of the major rivers.

Reconnaissance soil traverses over molybdeniferous Namurian shale west of the Onecote stream sediment anomaly confirm that the overburden here is mostly barren drift which accounts for the background values recorded in the local stream sediments.

miles

Fig 3 Incidence of hypocuprosis as reported before the regional geochemical survey (Information from National Agricultural Advisory Service, the Veterinary Investigation Service and private veterinary surgeons)

Analysis of soil and pasture herbage from selected plots in anomalous and background stream sediment areas showed a significant degree of correlation between the molybdenum content of the grass and clover and the supporting soil (Table 2) Though mean values for molybdenum in herbage are in each case higher on anomalous than on control soils, the contrast between anomalous and control vegetation is considerably less than that between the corresponding soils With regard to copper, no significant trend is apparent in the mean herbage values which range from 7–16 p p m , although soils from the anomalous plots contain 20–160 p p m of copper compared with 8–50 p p m in the controls

Agricultural Significance of Patterns

Land in the Onecote area is largely poorly or very poorly drained permanent pasture Farms are small and the land is difficult to improve The growing season is short because of the cold wet climate above 1,000 ft , mixed dairy farming is practised, but milk yields are low and stock is frequently in poor condition Farming in the Ashbourne area is again centred around dairying, with a small acreage of corn, but, being at a lower elevation and with a kinder climate than at Onecote, the farms are larger, methods more intensive and animals generally in better condition

The incidence of hypocuprosis in cattle, as reported before the geochemical reconnaissance, is shown in Fig 3 The greatest concentration was in two valleys in the Onecote area where the presence of molybdeniferous soil and herbage had suggested that the copper deficiency was molybdenum-induced, though the source of the molybdenum was not known with certainty (personal communication from D J C Jones) Comparison of the

reported incidence with the stream sediment pattern for molybdenum indicates an appreciable extension of the suspect area, particularly to the north of Onecote and also around Ashbourne where previous records showed only one herd-incidence of bovine infertility possibly due to copper deficiency (personal communication from C. M. Ford).

To test the agricultural significance of the results of the geochemical reconnaissance in terms of animal health, twenty-six herds comprising 350 cattle were selected for blood copper analysis. The selection was based solely on the distribution of molybdenum in stream sediment: nineteen of the farms were situated within the molybdenum anomaly and seven were in the adjoining background area. Farms where hypocuprosis had previously been reported were specifically excluded.

The results of these tests are summarized in Table 3 in terms of the numbers of deficient animals defined as those with less than the accepted lower normal limit of 0.08 μg of copper per 100 ml. of blood. Although the drawbacks of blood copper analysis as a means of diagnosing clinical hypocuprosis are realized, the principal conclusions, which are similar to those that may be drawn from the actual blood copper values, are as follows.

(1) There is a consistent trend towards a higher incidence of copper deficiency evident in animals of all age groups in both the Onecote and Ashbourne molybdenum-anomalous area as compared with the corresponding controls. This trend is particularly evident (*a*) in young stock (group II) from the Ashbourne area, where the blood copper data show mean values of 0.041 ± 0.004 and 0.095 ± 0.003 mg of copper/100 ml. of blood for anomalous and control groups, respectively, and (*b*) in adults receiving no supplementary feed (group III) in the Onecote area, where the corresponding blood copper values are 0.049 ± 0.004 and 0.090 ± 0.003. It is not known to what extent the limited incidence of copper deficiency observed in the control herds may be a result of (i) farm management, (ii) absolute copper deficiency on parts of the control farms and/or (iii) the local occurrence of patches of molybdeniferous soil too small in extent to influence the molybdenum content of the stream sediments predominantly derived from normal soils. The latter is not unlikely, as the majority of the controls lie within 3 miles of the anomalous stream sediment area.

(2) The effective improvement obtained in the molybdenum-anomalous area by feeding minerals is shown by the significantly smaller percentage of copper deficient adult stock of group IV compared with those receiving no mineral supplement in groups II and III ($P < 0.001$).

(3) Considering the combined data for both areas, the greater incidence of copper deficiency in animals from the anomalous areas compared with the controls is statistically significant in groups II and III ($P < 0.001$). Although it is not valid to compare the bulked data owing to unequal numbers of animals in the various groups, it is none the less impressive that of the total stock sampled, 64 per cent of the animals in the molybdeniferous areas were copper deficient compared with 35 per cent in the controls; excluding animals fed supplementary minerals, the corresponding percentages are 77 per cent and 37 per cent. In either case, the percentage incidence of copper deficiency within the molybdenum stream sediment pattern is approximately double that noted outside the anomaly.

Table 3. INCIDENCE OF COPPER DEFICIENCY (AS INDICATED BY BLOOD COPPER ANALYSIS) IN CATTLE, GROUPED ACCORDING TO AGE AND THE MOLYBDENUM CONTENT OF THE LOCAL STREAM SEDIMENT

Analysis was undertaken by the Central Veterinary Laboratory, Weybridge.

In several herds, the outward symptoms of copper deficiency were absent despite low blood copper values. Consequently, as a further test of the agricultural significance of the geochemical reconnaissance with particular reference to sub-clinical copper deficiency, supplementation trials were conducted on ten farms within the area of the molybdenum stream sediment anomaly. These experiments, which are being conducted in collaboration with advisers of the National Agricultural Advisory Service and the Veterinary Investigation Service, will be reported in full later. Preliminary results obtained for April–October show a mean increase of 5 per cent in the live weight gain of young cattle receiving injected copper compared with comparable untreated control animals. In some cases, the increased gain in weight was accompanied by a marked improvement in the physical appearance of the animals. Quite apart from the economic significance of these results, it is equally important that in many cases they were obtained on animals showing no clinical evidence of hypocuprosis.

Importance of Geochemical Reconnaissance

Geochemical reconnaissance by stream sediment sampling disclosed molybdenum anomalies covering a total area of 60 square miles in parts of Derbyshire and North Staffordshire. The anomalies are related to molybdeniferous rocks and soils. In places the pasture herbage is also molybdeniferous.

Copper deficiency induced by molybdenum was known to occur in parts of the anomalous stream sediment pattern. The results of blood copper tests carried out elsewhere within the anomaly indicate that all the anomalous area is suspect, the incidence of hypocuprosis being twice that observed outside the anomaly. Subsequent trials carried out within the anomalous area have shown that copper injections can increase the live weight gain of affected herds by more than 5 per cent. It is important that many of the animals which were found to be copper deficient and which responded to copper supplementation showed no outward symptoms of disorder.

In our view, the results fully confirm the potential value of regional geochemical reconnaissance as an aid in delineating suspect agricultural problem areas, wherein to concentrate detailed investigation using conventional methods which, though more precise, are far too costly and time consuming to be applied on the regional scale. The results also stress the unique advantage of the method in focusing attention on areas where clinical symptoms are absent yet where sub-clinical problems may be limiting agricultural productivity or where latent problems may adversely affect intensified farming in the future.

This work was assisted by the Natural Environment Research Council and the Institute of Geological Sciences. We thank the National Agricultural Advisory Service and the Veterinary Investigation Service for their co-operation, M. G. Davies for assistance in the Onecote area, and Miss C. N. Hebert for statistical advice. R. F. Horsnail took part in the reconnaissance sampling which was supervised by I. Nichol. Considerable help was also given by our analytical colleagues, under the direction of E. J. Newman and R. E. Stanton.

Binding of Formylmethionyl-*t*RNA to 30*S* Ribosomal Sub-units

by
M. A MUKUNDAN
JOHN W B. HERSHEY
KATHRYN F DEWEY
ROBERT E. THACH
Department of Chemistry, and
Department of Biochemistry and Molecular Biology,
Harvard University

Formylmethionyl-*t*RNA$_F$ seems to bind initially at the site used as a decoding site by all aminoacyl-*t*RNAs. A large part of this entry site must be located on the 30S ribosome particle, but some of it may extend to the 50S particle

THE requirements for correct initiation of protein synthesis in the *Escherichia coli* cell-free system include the following components ribosomes, formylmethionyl-transfer RNA$_F$ (F-met-*t*RNA$_F$), an initiator codon (ApUpG or GpUpG), two or three initiation factors, and GTP (refs. 1–6) Most of the details of the mechanism by which these components interact to form the first peptide bond are unknown The importance of the state of the ribosomes in this reaction has been emphasized recently[7–11]. It is clear that in the usual conditions (8–10 mM Mg^{++}) 70*S* ribosomes display little activity in initiation, whereas 30*S* particles, either alone or mixed with 50*S* particles, may be quite active[8,10]. In contrast, 70*S* particles are very active at about 5 mM Mg^{++} (ref 10). It seems likely that this lower Mg^{++} concentration optimum for 70*S* particles is a result of their ability to dissociate in these conditions into 50*S* and 30*S* sub-units. These facts are consistent with results[7] that suggest that *in vivo* the first steps of the initiation process do not occur on the 70*S* ribosomes, but rather involve the "native" 50*S* and 30*S* particles Nomura and Lowry[8] have proposed an initiation mechanism in which the interaction of *m*RNA, F-met-*t*RNA$_F$ and initiation factor(s) occurs on the 30*S* ribosome, this complex being subsequently joined by a 50*S* particle to form the active 70*S* ribosome

This article describes an investigation of the requirement for the formation of this initial complex involving the 30*S* particle Both native 30*S* particles and those derived from 70*S* ribosomes have been studied In both cases it has been found that GTP and initiation factors are required for the binding of F-met-*t*RNA$_F$ stimulated by ApUpG The bound product is not reactive with puromycin, whereas the addition of derived 50*S* particles to this complex renders the F-met-*t*RNA$_F$ sensitive to puromycin These results confirm the report of Hille *et al* [12] GMP-PCP can substitute for GTP in stimulating binding, but the complex formed does not react with puromycin in the presence of added 50*S* particles Both initiation factors (f_1 and f_2) are involved in the formation of the 30*S* complex

For purposes of comparison, we have made a preliminary investigation of the poly U-directed binding of phe-*t*RNA to 30*S* particles It has been found that this reaction is analogous to that involving F-met-*t*RNA$_F$ inasmuch as GTP (or GMP-PCP) and an enzyme are required. This enzyme does not seem to be an initiation factor, for it is found in the supernatant (*S*-100) fraction. A study of the requirement for GTP in this reaction has revealed that AMP-PCP (the adenosine analogue of GMP-PCP) can serve as a substitute, at about the same level of activity as GMP-PCP This surprising result suggests that the requirement for GTP in protein synthesis may not be as specific as previously supposed

Derived 30*S* and 50*S* particles were prepared by dissociating 70*S* ribosomes, which had been washed with NH$_4$Cl (ref 10), by overnight dialysis against buffer B [0 01 M *tris* HCl, *p*H 7 4, 0 1 mM Mg(OAc)$_2$, 0 05 M NH$_4$Cl, and 1 mM dithiothreitol], followed by sedimentation in a 5–20 per cent sucrose gradient containing buffer B. Fractions from this gradient containing 50*S* and 30*S* particles were pooled and the Mg^{++} concentration was increased to 10 mM The particles were pelleted by centrifugation at 105,000*g*, resuspended in buffer C [0 01 M *tris* HCl, *p*H 7 4, 0 01 M Mg(OAc)$_2$, 0 06 M KCl, 1 mM DTT] and stored at 0° C 30*S* particles prepared in this way were essentially free of contamination by 50*S* particles Conversely, 50*S* particles were considered to be essentially free of contamination by 30*S* particles, for they did not support the binding of detectable amounts of F-met-*t*RNA$_F$

Native ribosomes were prepared as follows. *S*-30 preparations from *E. coli* strain 1113 or *K*12, containing buffer A [0 01 M *tris* HCl, *p*H 7 4, 0 10 M NH$_4$Cl, 0 01 M Mg(OAc)$_2$ and 1 mM DTT] were centrifuged for 1 h at 105,000*g*, to remove polysomes, and the bottom fifth of the supernatant was diluted four-fold and layered on 28 ml of a 10–20 per cent convex sucrose gradient, and then centrifuged at 25,000 r p m. for 10 h at 5° C in a Spinco *SW*-25 rotor. Peaks containing 70*S*, 50*S* and 30*S* components were pooled, and the particles pelleted by centrifugation at 105,000*g* Each component was further purified by one or two more cycles of sucrose gradient sedimentation

Binding assays were conducted essentially as previously described[10], using *t*RNA fully charged with either ^{14}C-met (110 or 187 μCi/μm) or ^{3}H-phe (2 5 μCi/μm), nineteen cold amino-acids and cold formate In addition to the various macromolecular components, the amounts of which are given in the figure legends, binding reactions generally contained 10 mM Mg(OAc)$_2$, 0 1 M NH$_4$Cl, 0 05 M *tris* HCl, *p*H 7 4, and 1 mM dithiothreitol.

Initiation factors were prepared from *E. coli* strain 1113 or *K*12 essentially by the method of Lucas-Lenard and Lipmann[13]. Several preparations of f_1 were further purified by rechromatography on a column of DEAE-cellulose (in 0 02 M *tris* HCl, *p*H 7 4, 1 mM EDTA, 1 mM DTT), to remove any traces of contaminating f_2 These repurified f_1 preparations gave results indistinguishable from the starting material, suggesting that the standard purification procedures give f_1 free from f_2 contamination

In a previous communication[10] it was reported that the optimum Mg^{++} concentration for the binding of F-met-*t*RNA$_F$ to ribosomes depended strikingly on the manner of preparing the ribosomes undissociated 70*S* ribosomes were most active at 4–5 mM Mg^{++}, and virtually inactive at 10 mM, whereas a mixture of 50*S* and 30*S* particles (derived by previous dissociation of 70*S* ribosomes) displayed a broad optimum from 8 to 11 mM Mg^{++}. Inasmuch as these ribosomes were prepared by washing with a high concentration of salt [1 0 M NH$_4$Cl and 40 mM Mg(OAc)$_2$], it was interesting to determine whether the various classes of native ribosomes, which had not been exposed to such a high concentration of salt, would show similar Mg^{++} concentration profiles. The binding of F-met-*t*RNA$_F$ to native 70*S*, 30*S* and an equimolar mixture of 50*S* and 30*S* ribosomes, as a function of Mg^{++} concentration, is shown in Fig 1. The profiles are virtually identical to those obtained with 70*S* ribosomes prepared by washing with a high concentration of salt, on the one hand, and with a mixture of derived 30*S* and 50*S* particles,

Minus GTP, plus GMP-PCP	8 7	1 3

* The complete reaction mixtures contain 16 μμmoles of native 30*S* or 12 μμmoles of derived 30*S* particles 20 μg of charged *t*RNA, 33 μg of crude initiation factors, 0 1 μmoles of GTP or 0 01 μmoles of GMP-PCP, as indicated, 9 mμmoles of ApUpG, and NH$_4^+$, *tris* buffer and DTT as described in the text, in a final volume of 0 09 ml The final Mg^{++} concentration was 4 mM in this experiment, the same results were obtained at the usual 10 mM Mg^{++}

on the other[10] In addition, it is evident that native 30*S* particles alone (Fig 1*a*) display a profile similar to that of the mixture of native 50*S* and 30*S* particles (Fig 1*b*), and quite distinct from that of the 70*S* ribosomes (Fig 1*c*) In the case of the latter, it is again apparent that very little binding occurs at or above 10 mM Mg^{++}, whereas at 5 mM Mg^{++} these ribosomes are extremely active As suggested before[10], it seems likely that this very low Mg^{++} concentration optimum may result from the fact that 70*S* ribosomes, which as such may be incapable of binding F-met-*t*RNA$_F$, in these conditions begin to dissociate into actively binding sub-units*

Having established that mixtures of native ribosomal sub-units have an Mg^{++} concentration dependence similar to that of the derived sub-units, and that both preparations are markedly different from undissociated 70*S* ribosomes, we concentrated attention on the binding of F-met-*t*RNA$_F$ to 30*S* particles alone A study of the requirements for this reaction revealed that both GTP and initiation factors were needed for optimum binding This is true both for derived and native 30*S* particles (Table 1) This result shows that the sites of action of GTP and initiation factors (as is shown below, both f_1 and f_2 are involved in binding to 30*S*) are on the 30*S* particle That the complex is indeed specific for F-met-*t*RNA$_F$, as opposed to met-*t*RNA$_M$, is indicated by the fact that all the radioactivity bound in the 30*S* complex reacts with puromycin in the presence of 50*S* particles (see below), to give formylmethionyl-puromycin (F-met-puro) Furthermore, little or no binding of purified met-*t*RNA$_M$ to 30*S* particles could be detected in conditions optimal for F-met-*t*RNA$_F$ binding These results support the view that in the natural initiation process the 30*S* complex (containing F-met-*t*RNA$_F$, *m*RNA, initiation factors, GTP and a native 30*S* particle) is first formed and then subsequently is joined by a 50*S* particle[7,8] If this sequence of events is correct, it implies that the 50*S* particle may have little or nothing to do with the specificity of initiation [that is, the selection of F-met-*t*RNA$_F$ and the initiator codon(s) in the *m*RNA]

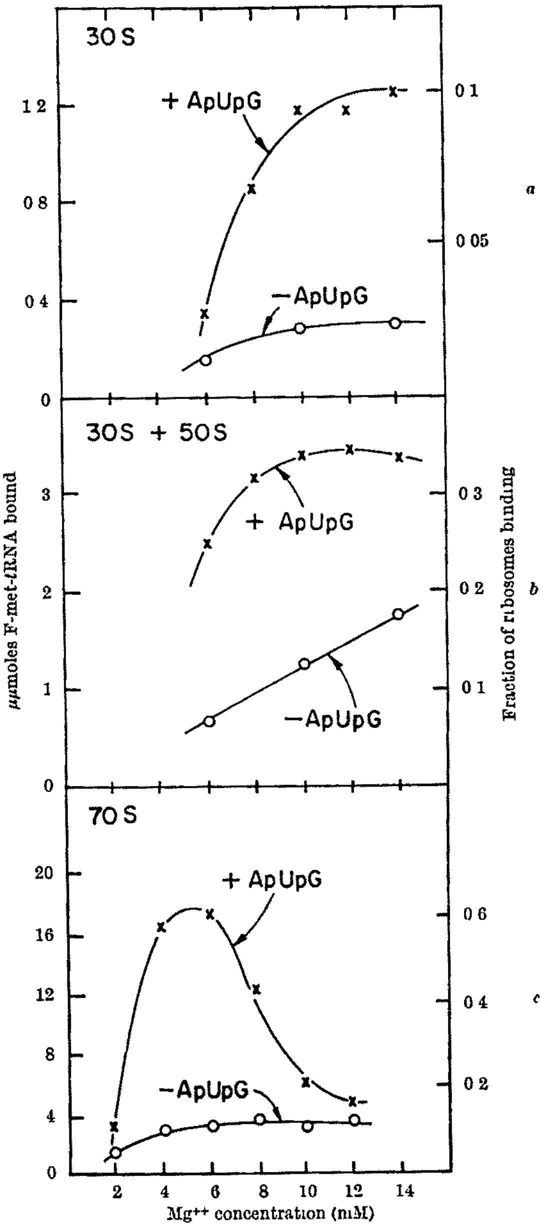

Fig 1 F-met-*t*RNA binding at various concentrations of Mg^{++} The final concentrations of ingredients are 0 05 M *tris* HCl, *p*H 7 4, 0 10 M NH$_4$Cl, Mg(OAc)$_2$ as indicated, 1 mM DTT, 0 40 mg/ml crude initiation factors, 0 6 mg/ml charged *t*RNA 0 5 mM ApUpG, and 1 0 mM GTP The amounts of ribosomes per aliquot are 12 5 μμmoles of native 30*S*, 10 μμmoles of each of native 30*S* and native 50*S*, 28 μμmoles of 70*S* Each binding mixture was filtered and washed with buffer containing the corresponding concentration of salts and Mg^{++}

An investigation of the specificity of the binding reaction has revealed that both GMP-PCP and AMP-PCP can replace GTP, whereas UTP and CTP are completely inactive (Tables 2 and 3) These results are quite consistent with those previously obtained when 70*S* ribosomes were employed[6,10]

Monro[14] has shown that the reaction between puromycin and F-met-*t*RNA$_F$ occurs on the 50*S* particle On the basis of this result one might anticipate that the F-met-*t*RNA$_F$ bound to 30*S* particles would not react with puromycin unless 50*S* particles were added The reactivity of F-met-*t*RNA$_F$ pre-bound to 30*S* particles was measured in the presence or absence of added 50*S* particles, and the results are shown in Table 4 It is clear that the F-met-*t*RNA$_F$ bound to 30*S* particles alone does not react with

---

* It is important to note that the Mg^{++} concentrations employed in the wash solutions for these experiments were also varied as shown in Fig 1 When, however the Mg^{++} concentration of the wash is maintained at 10 mM, considerable increase in the level of binding to 30*S* particles is observed when the Mg^{++} concentration in the reaction mixture is low (3–6 mM) This phenomenon accounts for the high activity at low Mg^{++} concentration reported in Tables 2 and 6

Table 3 NUCLEOSIDE TRIPHOSPHATE SPECIFICITY IN BINDING OF F-MET-*t*RNA TO 30*S* PARTICLES

Nucleoside triphosphate Added to complete system*	$\mu\mu$Moles F-met-*t*RNA bound
None	0 8
GTP	4 5
GMP-PCP	4 2
AMP-PCP	3 9
UTP	0 8
CTP	0 8

* The complete reaction mixture contains 6 6 $\mu\mu$moles of derived 30*S* particles, 38 μg of charged *t*RNA, 26 μg of partially purified factor (f_2), 0 05 μmoles each of GTP, UTP, CTP and AMP-PCP, 0 001 μmole of GMP-PCP, 7 mμmoles of ApUpG, and Mg^{++}, NH$_4^+$, *tris* buffer and DTT as described in the text, in a final volume of 0 04 ml

puromycin, whereas the subsequent addition of 50*S* particles renders it reactive Furthermore, when GMP-PCP is substituted for GTP, the bound F-met-*t*RNA$_F$ does not react in any circumstances These results are consistent with the fact that peptide bond formation occurs on the 50*S* particle[12,14], and that the role of GTP in initiation involves two or more sequential functions, only the first of which can be fulfilled by GMP-PCP[10] Furthermore, it is clear that the first of these functions involves the binding of F-met-*t*RNA$_F$ to the 30*S* particle, a reaction in which the GTP molecule is not hydrolysed

Plus 50*S*	5 1	1 00
Complete (GMP-PCP)	1 0	0 98
Plus 50*S*	1 0	1 02

* Reaction mixtures contained 15 $\mu\mu$moles of derived 30*S* particles, 25 μg of charged *t*RNA, 20 μg of initiation factors, 9 mμmoles of ApUpG, 0 08 μmoles of GTP or 0 11 μmoles GMP-PCP as indicated, and Mg^{++}, NH$_4^+$, *tris* buffer and DTT as described in the text, in a final volume of 0 085 ml Incubation was at room temperature for 20 min

† Reaction mixtures were prepared and incubated as in the binding reactions, after which 11 $\mu\mu$moles of derived 50*S* particles was added and the incubation was continued for 20 min at room temperature The reaction mixture was then kept at 0° C, treated with 50 μg of puromycin dihydrochloride and incubated for 3 min F-met-puro synthesis was assayed as previously described[10]

Having found that a crude preparation containing initiation factors stimulated the binding of F-met-*t*RNA$_F$ to 30*S* particles, it seemed important to determine which of the two factors, f_1 and f_2, was responsible for this activity These factors were partially purified as described already, and assayed both individually and together for their ability to stimulate binding to derived 30*S* particles The results of these experiments are shown in Fig 2 It is clear that each factor is active by itself, although maximum binding is obtained only in the presence of both This result is qualitatively similar to those obtained by others using uncharacterized ribosome preparations[3,13], although the relative activity of f_1 reported here is higher than has been observed before Similar results were obtained with f_1 prepared from *E coli* strains *K*12 and 1113, and with samples further purified by rechromatography on DEAE-cellulose to remove possible traces of contaminating f_2 Native 30*S* particles show a pattern of response to f_1 and f_2 which is similar to that observed with derived 30*S*, although the results are less conclusive because of the higher blank values obtained with these preparations Thus there seems to be little basic difference between native and derived 30*S* particles While it is likely that native 30*S* particles are loosely associated with initiation factors *in vivo*[9], the purification procedure used here apparently removes them

The surprising lack of any obvious functional difference between f_1 and f_2 is puzzling on several accounts First, it is difficult to understand why both are present when either one alone displays such high activity It seems possible that one of the factors is contaminated with the other, perhaps in the form of a specific complex between the two (this would account for their clear physical separability on columns of DEAE-cellulose) Second, the activity observed with f_1 alone is considerably higher than that previously reported[3,13] It seems possible that both these anomalies stem from the same source, namely, that the system employed here is quite different in many respects from those used elsewhere In particular, in our system the fraction of 30*S* particles which bind F-met-*t*RNA$_F$ (that is, the efficiency) is between 10 and 400 times higher than that reported by others[8,12] Furthermore, in our hands f_1 activity is extremely unstable, whereas f_2 seems to be more stable As a result of this instability, the level of binding observed with f_1 alone varies from 20 per cent to 70 per cent of the maximum obtainable with both factors present, depending on the age and manner of storage of the preparation

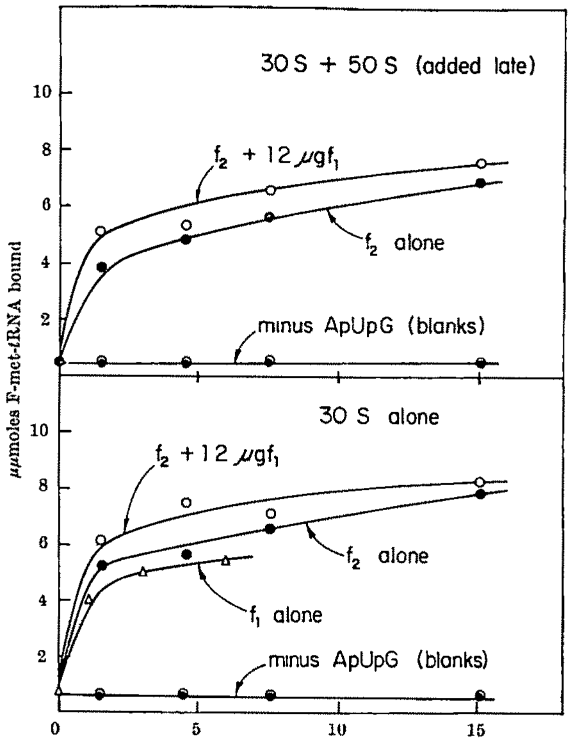

Fig 2 Effect of purified initiation factors, f_1 and f_2, on binding of F-met-*t*RNA to derived 30*S* particles Reaction mixtures contained 11 $\mu\mu$moles of 30*S* particles, 15 $\mu\mu$moles of 50*S* particles (top figure only), 25 μg of charged *t*RNA, factors as indicated, 9 mμmoles of ApUpG where indicated, 0 08 μmoles of GTP, and Mg^{++}, NH$_4^+$, *tris* buffer and DTT as described in the text, in a final volume of 0 1 ml

It was interesting to determine whether the F-met-*t*RNA$_F$ bound in the presence of only one of the initiation factors could react with puromycin, after the addition of 50*S* particles Experiments to investigate this possibility were conducted essentially as described in Table 4, and the results are shown in Table 5 It is clear that either of the factors alone will support F-met-puro synthesis,

Table 5 EFFECT OF f_1 AND f_2 ON F-MET-PURO SYNTHESIS

	$\mu\mu$Moles of F-met-puro Plus ApUpG	$\mu\mu$Moles of F-met-puro Minus ApUpG

* The complete reaction mixture in experiment 1 contains 8 0 $\mu\mu$moles of derived 30*S* particles, 25 μg of charged *t*RNA, 50 μg of supernatant enzymes, 0 1 μmole of GTP, 15 μg of poly U, 5 mM of Mg $(OAc)_2$, and NH_4^+, *tris* buffer and DTT as described in the text, in a final volume of 0 09 ml

† The complete reaction mixtures in experiments 2 and 3 contain 6 6 $\mu\mu$moles of 30*S* particles, 10 μg of charged *t*RNA, 25 μg of supernatant enzymes, 0 05 μmoles of GTP, 0 001 μmole of GMP-PCP, 0 05 μmole of AMP-PCP, as indicated, 7 5 μg of poly U, and Mg^{++}, *tris* buffer and DTT as indicated in the text

although the maximum level is obtained only when both factors are present.

Having investigated the requirements for the binding of F-met-*t*RNA$_F$ to 30*S* particles, we next examined the binding of an aminoacyl-*t*RNA, phe-*t*RNA, for the purpose of comparison. It was hoped that such a comparison might shed light on the question of whether F-met-*t*RNA$_F$ initially binds at the same site as other *t*RNAs, that is, the "*A* site" or "single entry site"[10] A preliminary study of the requirements for the binding of phe-*t*RNA to 30*S* particles, directed by poly U, is shown in Table 6 It is clear that both a supernatant enzyme or enzymes present in the *S*-100 fraction and GTP are required for binding, and that AMP-PCP and GMP-PCP can partially replace GTP (recent experiments with GMP-PCP have indicated a greater activity than is evident in Table 6, that is, about half the activity obtained with GTP) That the requirement for nucleoside-triphosphate is specific for the binding step, and that no polypeptide synthesis occurs, is indicated by the following facts (*a*) none of the bound radioactivity is precipitable in hot TCA, and (*b*) neither GMP-PCP nor AMP-PCP support polypeptide synthesis.

Other preliminary experiments suggest that the Mg^{++} concentration dependence for phe-*t*RNA binding is similar to that observed with F-met-*t*RNA$_F$, and that both reactions are inhibited by tetracycline, a drug thought to be specific for the *A* site (ref 15 and unpublished results of S Sarker)

These results show that the requirements for the binding of phe-*t*RNA to 30*S* particles are very similar to those observed for F-met-*t*RNA$_F$ binding The chief difference between the two reactions lies in the nature of the enzymes involved Whereas the supernatant enzyme required for the binding of phe-*t*RNA is probably *T*-factor[16,17], it is not clear whether f_1 or f_2 performs a strictly analogous function in the case of F-met-*t*RNA$_F$ Indeed, it seems possible that one of the initiation factors is actually a modified *T*-factor that is specific for F-met-*t*RNA$_F$, this is suggested by the similarity in the nucleoside triphosphate requirements for the two binding reactions Such a mechanism would, of course, be consistent with the view that F-met-*t*RNA$_F$ initially binds at the same site usually used as a decoding or entry site by all aminoacyl-*t*RNAs It is clear that much of this entry site must be located on the 30*S* particle, however, it also seems possible that this site actually extends to the 50*S* particle to include the site specific for the aminoacyl moiety of aminoacyl-*t*RNA (ref 14) This overlapping site would be equivalent to the *A* site as previously envisaged[5]

Cambridge

An unstable haemoglobin causing inclusion-body anaemia is described Its amino-acid substitution is in the haem pocket of the α chain, homologous in position to that in Haemoglobin Hammersmith (β CD1 Phe→Ser) The two disease states differ and an explanation is attempted in terms of molecular structure

A CARPENTER from Treviso, Italy, was repeatedly admitted to hospital in Torino from the age of 36 because of haemolytic crises One occurred after treatment with a sulphonamide derivative, when 60 per cent of the circulating red cells contained Heinz bodies After splenectomy he worked for 7 years without requiring any blood transfusions In 1967, nearly 80 per cent of the red cells contained Heinz bodies, the half life of the red cells was measured by tagging with ^{51}Cr, and $T\frac{1}{2}{}^{51}$Cr was found to be only 16 days The fresh blood contained 4 7 per cent of methaemoglobin, and this level increased considerably

---

* On leave from the Institute of Medical Pathology, Torino

		⇡				↑										

The arrows show where chymotryptic cleavage was demonstrated, and the dotted arrow indicates that hydrolysis at this point is only partial

on incubation for 48 h, even when glucose was added The haemolysate formed a copious precipitate on mild heating[1] The patient has three children, supposedly healthy

The presence of Heinz bodies, the increased proportion of methaemoglobin and the tendency to convert to methaemoglobin on incubation, together with the fact that the haemoglobin could be precipitated by mild heating, suggested that the cause of the anaemia was an unstable haemoglobin These haemoglobins become more easily converted to methaemoglobin, which precipitates and forms Heinz bodies[2,3]

The severe haemolytic crisis following treatment with the sulphonamide derivative could also have been associated with unstable haemoglobin In normal haemoglobin, as in myoglobin, protection of the haem against oxidation of its ferrous ion is due to its being buried in a tightly fitting fold within the globin This fold is held together by the hydrophobic bonding (van der Waals forces) exercised by the internal amino-acid residues lining the pocket[4] In one group of unstable haemoglobins one of these internal residues has been replaced by another of different shape[5] This causes a change in the configuration of the haem pocket, water can enter it, and in the presence of oxygen and water iron is oxidized, that is, methaemoglobin is formed[2] Methaemoglobin loses its haem ten times more easily than oxy or deoxy haemoglobin[6] Mild oxidizing agents, such as sulphonamide at dosages which cause no such oxidation to methaemoglobin in normal red cells, will oxidize the haem in haemoglobin when the haem pocket is disarranged For example, Haemoglobin Zurich (β63 His→Arg) was discovered because sulphonamide had caused haemolysis[7]

Investigation of the Haemoglobin

Electrophoresis of the haemolysate yielded no abnormal fraction On warming to 50° C at *p*H 7 4 (ref. 1) some of the haemoglobin precipitated Haemoglobin solutions were submitted to paper electrophoresis at *p*H 8 9, until the haemoglobin A fraction had moved well from the origin It had thus been separated from any non-haemoglobin fractions which contain heat-labile material The haemoglobin A fraction was eluted from paper and the eluate was concentrated by vacuum dialysis It was then incubated at 50° C (phosphate buffer *p*H 7 4) for 20 min A precipitate appeared which was washed three times with the same buffer which had been brought to a temperature of 50° C The washed haemoglobin precipitate was dissolved in 0 1 N HCl, and precipitated in acetone to obtain the globin After washing three times with acetone the precipitated globin was dried and digested with trypsin for the preparation of fingerprints or peptide chromatograms The techniques used in this laboratory for the preparation of fingerprints and for the specific colour reactions to identify peptides containing histidine, tyrosine, tryptophan and methionine have recently been summarized[8]

Fig 1 shows a fingerprint of the precipitate All the soluble peptides expected are found in the normal position Below the tryptic peptide of the α chain which contains residues 41–56 (see Table 1) of the 141 α chain residues (αTpVI) another peptide can, however, be noted

As expected, colour reactions showed the presence of tyrosine and histidine in αTpVI and these were positive also for the peptide below αTpVI which had the same electrophoretic mobility but was less hydrophobic on chromatography

It has been pointed out[5] that there is a general pattern for unstable haemoglobins which do not separate from haemoglobin A on electrophoresis If present together with haemoglobin A the fingerprint shows, in addition to one of the peptides in the normal position, another with the same electrophoretic but a lower chromatographic mobility This is caused by the replacement of one amino-acid by another less hydrophobic amino-acid carrying the same charge

It was concluded that the purification of the unstable haemoglobin had been only partial and that the precipitate which had been used for fingerprinting contained both normal and unstable αTpVI By more gentle heat precipitation—15 min at 45° C—we have obtained a haemoglobin preparation in which only the abnormal peptide was present

Table 2 shows the results of amino-acid analysis of the two peptides and it will be seen that their composition differs in one amino-acid residue In the abnormal peptide one of the two phenylalanine residues is missing, and two residues of valine are present instead of one To find which of the two phenylalanine residues had been replaced, α43 or α46, both peptides were submitted to chymotryptic digestion In the normal peptide Hill and Konigsberg[9] had described cleavage at Tyr 42 and at Phe α46 (CD4), but not at Phe α43 and Leu 48 Phe α43

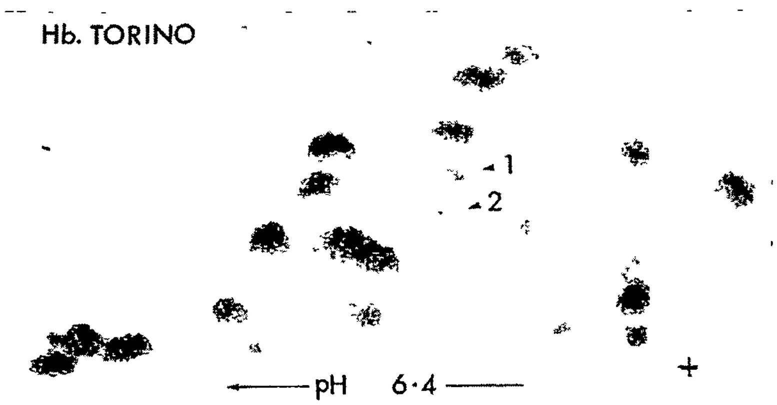

Fig 1 Fingerprint of partially purified haemoglobin Torino (1) α^{A}TpVI, (2) α^{Torino}TpVI In position 43 (CD1) α^{A}TpVI carries a phenylalanine residue and α^{Torino}TpVI one of valine

Table 2 AMINO-ACID COMPOSITION OF NORMAL AND ABNORMAL αTpVI

Amino-acid	μmoles A	Torino	No of residues A	Torino
Aspartic acid	0 017	0 018	1 0	0 9
Threonine	0 016	0 022	1 0	1 1
Serine	0 035	0 036	2 2	1 9
Glutamic acid	0 016	0 022	1 0	1 1
Proline	0 016	0 017	1 0	0 9
Glycine	0 020	0 023	1 3	1 2
Alanine	0 018	0 019	1 1	1 0
Valine	0 018	0 037	1 1	1 9

Tyrosine	0 014	0 019	0 9	1 0
Phenylalanine	0 027	0 020	1 7	1 0
Histidine	0 065	0 031	2 3	2 3
Lysine	0 028	0 038	1 0	1 0

Glutamine appears as glutamic acid after the acid hydrolysis of the peptide which precedes amino-acid analysis Histidine and lysine were estimated separately, hence there are different yields per residue for these basic amino-acids from those of neutral and acidic amino-acids

is protected against chymotrypsin because it is bonded to a proline residue, chymotryptic hydrolysis at Leu α48 is presumably counteracted by the acidic residue Asp α47 Chymotryptic digestion of the normal αTpVI resulted in the expected four peptides 41–46, 41–42, 43–46 and 47–56 The same procedure was applied to the abnormal peptide and gave exactly the same results, indicating that cleavage took place at Phe α46 (CD4) There was, however, a slightly lower chromatographic mobility of peptide 41–46 and 43–46 A valine residue at position α46 (CD4) would not be subject to tryptic hydrolysis, and so the result was interpreted as showing that the residue at α46 (CD4) was phenylalanyl, and that the Phe→Val substitution had occurred at α43 A replacement of phenylalanyl by valyl at this position would be expected to decrease slightly the chromatographic mobility of the chymotryptic peptides 41–46 and 43–46 To verify the exact location of the Phe→Val substitution in the abnormal peptide, it was treated by a combined Dansyl-Edman sequencing method[10] All procedures were carried out also on normal αTpVI as a control

Two preparative fingerprints were prepared each with 9 mg of globin and from both the two peptides were eluted with 0 5 M ammonia The ammonia was removed in a desiccator and the dried material was re-dissolved and submitted to stepwise degradation of the N terminal residues according to Edman After removal of two N terminals each, the new N terminal was dansylated and after hydrolysis identified by polyamide layer chromatography[11]

In this way it was shown that the third residue of normal αTpVI yielded dansyl-phenylalanine and that of the abnormal peptide dansyl-valine The haemoglobin under investigation was therefore a new and so far undescribed variant, an unstable haemoglobin with a substitution in the α chain haemoglobin Torino α43 (CD1) Phe→Val

By combining mild heat denaturation with fingerprinting of the precipitate it could be established that haemoglobin Torino amounted to 8 per cent of the total haemolysate This figure would not include any haemoglobin Torino present as Heinz bodies in the red cells, for these would be removed when the haemolysate is prepared

Haemoglobin Torino is the first unstable haemoglobin to be observed with an amino-acid substitution in the haem pocket of the α chain It is notable that it conforms with the pattern observed in unstable haemoglobins with abnormality of the β chain haem pocket, that is, there is a replacement of an internal amino-acid residue by another with the same charge but less efficient in hydrophobic bonding[5] A previously described unstable haemoglobin—Hammersmith—has its substitution at the homologous site of the β chain CD1 Phe→Ser (ref 12)

Haemoglobin Hammersmith disease is more severe than haemoglobin Torino disease The first causes considerable anaemia in early childhood, and survival to adult age without blood transfusions, as has been the case in the patient with haemoglobin Torino, might have been unlikely in patients with haemoglobin Hammersmith (ref 13 and personal communication from N K Shinton)

There are a number of possible explanations for the greater severity of haemoglobin Hammersmith disease (β CD1 Phe→Ser) as compared with haemoglobin Torino disease (α CD1 Phe→Val), of which four may be mentioned here

(1) The phenylalanyl at CD1 of normal haemoglobins is an invariant residue and is found in this position in all known globins[4] It stabilizes the haem by direct contact and one would expect replacement by an amino-acid with a shorter side chain to cause instability Of the two replacements, serine resembles phenylalanine less than valine does It has a shorter side chain, and, whereas valine and phenylalanine are both non-polar, serine is polar and can form hydrogen bonds either internally or with the surrounding water[14] Thus a replacement of phenylalanine by serine might be expected to cause more instability than a replacement by valine

(2) It is noticeable that the soluble haemoglobin in haemoglobin Hammersmith disease includes 30 per cent of the abnormal pigment, but in haemoglobin Torino disease only 8 per cent of the soluble haemoglobin is abnormal This lower proportion of haemoglobin A in heterozygotes possessing haemoglobin A plus an α chain variant of A has usually been observed For example, in haemoglobins α A13 and β A13 Glu→Asp (haemoglobins J Oxford and J Baltimore) the proportion of haemoglobin A in the heterozygote is higher in the case of haemoglobin J Baltimore than in that of J Oxford[15] The normal α chain gene can if necessary make considerably more than 50 per cent of the total α chains Presumably the pathological risk for an erythrocyte is greater when the level of unstable haemoglobins is higher, and thus the red cells in haemoglobin Hammersmith disease would be more vulnerable than those in haemoglobin Torino disease

(3) There are indications that the α chain haem is less easily removed than the β chain haem[16] The interaction of haem with globin stabilizes the molecule as a whole[17] and the mere loss of haem from myoglobin results in a considerable change of molecular conformation[18] Thus a better hold on the haem by the α chains *per se* might contribute to make haemoglobin Torino disease less severe than haemoglobin Hammersmith disease

(4) Oxidation of the α and β chains occurs stepwise—at first the β93 cysteine residue is oxidized, and the oxidation of the second cysteine residue of the β chain and of the only cysteine residue of the α chain, β112 and α104, follow later[19] Thus a normal β chain may extend some protection even to unstable α chains

Amber Suppression: a Nucleotide Change in the Anticodon of a Tyrosine Transfer RNA

by

HOWARD M. GOODMAN
JOHN ABELSON
ARTHUR LANDY
S. BRENNER
J. D. SMITH

MRC Laboratory of Molecular Biology, Cambridge

In certain mutants a single base change alters the meaning of a messenger codon in such a way that, instead of spelling out an amino-acid, it spells out chain termination. Mutants in a quite different gene, called a suppression gene, allow the chain-terminating triplet to be read as an amino-acid. Experiments have shown that this is caused by a mutated tRNA which carries a single base change in its anticodon. This allows it to read the chain-terminating codon as if it spelt tyrosine.

In *Escherichia coli* the amber codon UAG is one of the three "nonsense" triplets (reviewed in ref. 1) that code as signals for termination of messenger RNA translation. Strains of *E. coli*, which allow translation of UAG as an amino-acid and subsequent propagation of the polypeptide chain, result from mutation in one of several suppressor genes. There are two classes of UAG suppressors: first, ochre suppressors which permit both UAG and the related chain terminating triplet UAA to be read with low efficiency, and, second, the relatively efficient amber suppressors which are specific for UAG. It has been shown for three amber suppressors that suppression is caused by the presence of an altered *t*RNA in the su^+ cell[2-5]. Although there was no doubt that the suppressor itself was a *t*RNA molecule, these experiments did not show how the suppressor gene acts. It could, for example, control the synthesis of a *t*RNA not present in su^- cells, or of an enzyme which modifies *t*RNA. More simply it could specify the sequence of a *t*RNA. We will show that the amber suppressor su_{III} gene is the structural gene for one of the tyrosine *t*RNAs of *E. coli* and that the mutation su^-_{III} to su^+_{III} results in a base change in the anticodon of this *t*RNA.

The nature of the mutational change is shown by comparison of the nucleotide sequences of the su^+_{III} tyrosine *t*RNA and the corresponding *t*RNA specified by the su^-_{III} allele. The su_{III} suppressor *t*RNA is a small part of the total tyrosine *t*RNA in the cell. The rest of the tyrosine *t*RNA consists of two species (I and II). To overcome this difficulty we used a technique designed greatly to increase the amount of su_{III} gene product in the cell by increasing the number of copies of the gene. The su_{III} gene, which maps very near to the attachment site of phage φ80, was placed on a defective transducing φ80. Infection of *E. coli* with the transducing phage resulted in a phage DNA pool containing many copies of the su_{III} gene. In this way, the amount/cell of the su_{III} gene product, su_{III} tyrosine *t*RNA, was greatly increased. This technique also allows selective isotopic labelling of the *t*RNA for sequence determination.

Transducing Phage φ80 carrying the su_{III} Gene

In the experiments described here, a particular defective transducing phage φ80 dsu^+_{III} (V) was used[4]. The su^+_{III} gene was isolated as a spontaneous mutant from an su^-_{III} strain. The homologous phage, transducing the wild type allele, φ80 dsu^-_{III}, was derived as a recombinant from heterozygous strains lysogenic for φ80 dsu^+_{III}. Thus φ80 dsu^-_{III} and φ80 dsu^+_{III} are identical except for the single spontaneous mutation which produced the su^+_{III} allele.

Synthesis of su_{III} Tyrosine tRNA after Infection by φ80 dsu_{III}

Infection of *E. coli CA*274 (su^- lac^- amber) with φ80 dsu^+_{III} resulted in the appearance of suppressor activity as measured by the suppression of an amber mutation in the β galactosidase gene. This was closely paralleled by an increase in the amount of tyrosine *t*RNA in the cell (Fig. 1). No increase occurs in the relative proportion of any other *t*RNA.

Ribosome binding experiments with the *t*RNA synthesized after infection with φ80 dsu^+_{III} showed that the su^+_{III} strains contain a tyrosine *t*RNA which recognizes the amber codon. The corresponding *t*RNA in cells infected with φ80 dsu^-_{III} recognizes the normal tyrosine codons UAU and UAC[4]. Although these experiments do not prove that the suppressor gene specifies a tyrosine *t*RNA, this, however, is likely because φ80 dsu^+_{III} does contain a structural gene for tyrosine *t*RNA as shown by specific hybridization of tyrosine *t*RNA with the DNA from this phage[6].

Nucleotide Sequences of su^+_{III} and su^-_{III} Tyrosine tRNAs

If the su_{III} gene is the structural gene for a tyrosine *t*RNA, we expect that the mutation from the su^-_{III} to su^+_{III} allele will have produced a nucleotide change in the su_{III} *t*RNA. To test this idea we have determined the nucleotide sequence of the su^+_{III} tyrosine *t*RNA and compared it with that of the su^-_{III} *t*RNA.

The su^+_{III} *t*RNA labelled with phosphorus-32 was prepared as previously described[6] or by a slightly modified procedure (see legend of Fig. 1). The selective labelling of su_{III} tyrosine *t*RNA after infection was evident from the high proportion of *t*RNA labelled with phosphorus-32 eluting with tyrosine *t*RNA during purification on the DEAE 'Sephadex' column. Pooled fractions from this region often contained about 70 per cent radiochemically pure tyrosine *t*RNA and were sufficiently homogeneous

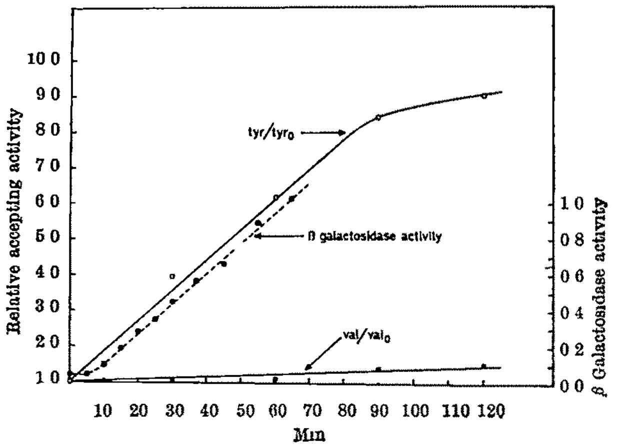

Fig 1 Increase of tyrosine *t*RNA and suppressor activity in *E coli CA274 su⁻ lac⁻* amber following infection by φ80 *dsu*$_{\mathrm{III}}^{+}$ *E coli CA274* was grown to 2×10^8 cells/ml in LP medium[6] The cells were collected by centrifugation and concentrated ten-fold in preconditioned LP medium $MgSO_4$ was added to 0 02 M and the cell suspension was irradiated with ultraviolet light for 90 s This dose kills 70 per cent of the cells The culture was then infected with 30 φ80 *dsu*$_{\mathrm{III}}^{+}$ particles/bacterium After adsorption for 7 min the cell suspension was diluted ten-fold in preconditioned media Two separate experiments are shown In one experiment, the suppression of an amber mutation in the β-galactosidase gene was measured by assaying enzyme activity at various times after dilution into the growth medium One mM of isopropylthiogalactoside was added to induce the β-galactosidase In the second experiment, aliquots of the infected culture were removed, *t*RNA was extracted, and tested for its ability to be acylated with several different amino-acids Fifty μg/ml of chloramphenicol added at 25 min prevented lysis which normally occurs at 60 min after dilution In experiments where the *t*RNA is labelled with ^{32}P, 0 05 m Ci/ml is added 5 min after dilution of the infected cells and the culture is collected after 2 h

for some of the nucleotide sequence work In other cases, these fractions were further purified by either of two chemical methods which depend on the ability of the *t*RNA to be acylated with tyrosine[7,8]

The sequence of the su_{III}^{+} tyrosine *t*RNA labelled with phosphorus-32 was determined using the methods of Sanger *et al* [9,10] The end-products of complete digestion with T_1 ribonuclease or pancreatic ribonuclease were separated on a two-dimensional electrophoretic system and their sequences determined by further enzymatic digestion. These are listed in Table 1 The combination of products from the two enzyme digests gave only two significant overlaps—GAAGGTψCG and CCAAAGGGAGC

To overlap the remaining end-products, larger fragments were obtained by partial enzyme digestion and separated as described before[11] The sequences of these partial fragments were determined from the complete products of their digestion with T_1 ribonuclease and pancreatic ribonuclease About one hundred large fragments were obtained by partial digestion with various enzymes and their sequences were determined. Fig 2 shows a selected set of fragments from which the complete sequence was deducted Fig 3*a* shows the su_{III}^{+} tyrosine *t*RNA sequence arranged in the "clover leaf"

pattern characteristic of the yeast *t*RNA structures For comparison, the sequence of yeast tyrosine *t*RNA as determined by Madison, Everett and Kung[12] is shown in Fig 3*b*. Note that in su_{III}^{+} tyrosine *t*RNA, CUA is in the position expected for the anticodon

There is only a single nucleotide difference between the su_{III}^{+} and su_{III}^{-} tyrosine *t*RNAs and this is best illustrated by comparison of their T_1 ribonuclease digestion products Fig. 4 compares the fingerprints of the T_1 ribonuclease digestion products of the two *t*RNAs

Comparison of the T_1 products shows that oligonucleotide 17, ACUCUAA*AψCUG, in the su_{III}^{+} *t*RNA is replaced in the su_{III}^{-} *t*RNA by the two oligonucleotides ACUG and UAA*AψCUG For the moment we will ignore the presence in the su_{III}^{+} fingerprint of oligonucleotide 17a (which is related to 17); its significance will be discussed later There are no differences in any other T_1 ribonuclease digestion products In the su_{III}^{-} *t*RNA the sequence corresponding to oligonucleotide 17 (su_{III}^{+}) must therefore be ACUGUAA*AψCUG which is split by T_1 ribonuclease to give ACUG and UAA*AψCUG The sequence GUA in su_{III}^{-} *t*RNA is thus changed to CUA in the su_{III}^{+} *t*RNA GUA is the expected anticodon for the dual recognition of the tyrosine codons UAU and UAC (ref 13) and in fact GψA is found in the expected anticodon position of yeast tyrosine *t*RNA (Fig 3*b*) which recognizes both these codons[14] CUA is the anticodon expected for the unique recognition of the amber codon UAG. In the complete sequence (Fig 3*a*) of su_{III}^{+} *t*RNA, CUA occupies the anticodon position These results show that the mutational event giving rise to the su_{III}^{+} allele can be accounted for by a G to C change in the structural gene for a tyrosine *t*RNA.

G in the Anticodon is Normally Modified

In these experiments, the su_{III}^{-} *t*RNA had an unmodified G in the first position of the anticodon Normally, however, the G in the anticodon of the su_{III}^{-} tyrosine *t*RNA is

Su+ Tyrosine tRNA E coli

(*a*)

Tyrosine tRNA Yeast

(*b*)

Fig 3 Clover leaf models of *E coli* and yeast tyrosine *t*RNAs The sequence of the su^+_{III} tyrosine *t*RNA is shown with the differences that occur in su^-_{III}, and species I and II (*a*) For identification of the minor bases see Fig 4 and the text The su^-_{III} and species I tyrosine *t*RNAs have identical sequences and differ from su^+_{III} in having a G* in the anticodon Species II *tyr* *t*RNA has the same anticodon sequence containing G* but is different in two positions where the T_1 ribonuclease product UCAUCG is replaced by UCACAG The latter oligonucleotide has been independently identified by B P Doctor and S Nishimura The sequence of the yeast tyrosine *t*RNA is taken from Madison *et al*[12] (*b*) The sequences enclosed in solid boxes are common to all the five yeast *t*RNA structures so far determined (neglecting differences in modification), while those enclosed in dotted boxes are common to most of the sequences

a modified guanine derivative (G*) In su_{III} tyrosine *t*RNA synthesized in conditions where the cells were starved before infection[6] we have observed that A^+ and $G_{2'OMe}$ remain largely unmodified The same is true of the G residue in the anticodon In su^-_{III} *t*RNA prepared from cells not starved before infection (legend to Fig 1), the G residue in the anticodon is partly or completely modified to G* This is not split by T_1 ribonuclease so that the T_1 ribonuclease product containing the anticodon is $\text{ACU}\underline{\text{G*UAA}}\text{*A}\psi\text{CUG}$ The same anticodon G*UA also occurs in the two principal tyrosine *t*RNA components of *E. coli* (Fig 3*a*, I and II), and therefore it was possible to isolate small quantities of non-radioactive G^*_p to study its properties G^*_p has an ultraviolet absorption spectrum very similar to that of G_p It differs from G_p in having an additional basic group with a pK_a between 5 and 6 Neither T_1 nor pancreatic ribonuclease splits the anticodon at the position of G^*_p and hence in a pancreatic ribonuclease digest it is obtained as the dinucleotide $G^*_pU_p$ From ribosome binding studies on *E coli* tyrosine *t*RNAs it is clear that G* has the same codon recognition properties as G The nature of the modification (which we suspect is on the imidazole part of the purine ring) and its biological significance remain unknown

Heterogeneity of su^+_{III} Tyrosine *t*RNA

In the su^+_{III} *t*RNA T_1 ribonuclease fingerprint we noted the presence of an additional oligonucleotide 17a (Fig 4) This has the sequence $\text{ACU}\underline{\text{G*UAA}}\text{*A}\psi\text{CUG}$ and is present in amounts varying between 20 per cent and 40 per cent of the su^+_{III} anticodon-containing T_1 product $\text{ACU}\underline{\text{CUAA}}\text{*A}\psi\text{CUG}$ The sum of the two is in molar yield in the *t*RNA Thus the tyrosine *t*RNA synthesized after infection by φ80 dsu^+_{III} contains in addition to su^+_{III} *t*RNA a smaller proportion of a tyrosine *t*RNA with the su^- anticodon sequence As will be shown later, the tyrosine *t*RNA in *E coli* can be separated into two kinds of molecules One of these, tyrosine *t*RNA I, has the same sequence as the su^- *t*RNA The other tyrosine *t*RNA II, differs by two nucleotides Fingerprints of the su^+_{III} tyrosine *t*RNA exclude the presence of tyrosine *t*RNA II as the source of the contaminating su^- anticodon sequence. We have considered four possible explanations for this. (i) The φ80 dsu^+_{III} carries an additional tyrosine *t*RNA gene determining the structure of tyrosine *t*RNA species I This is not supported by hybridization experiments between φ80 dsu^+_{III} DNA and tyrosine *t*RNA, which show that the transducing phage carries a single *t*RNA gene[6] (ii) The φ80 dsu^+_{III} phage preparations always contain a proportion of φ80 dsu^-_{III} transducing phage Such phages could be produced by abnormal excisions occurring in the induction of the heterogenote We have no good method of assessing the frequency of such events although the general phenomenon is known to occur[15] (iii) The transcription of genes near the φ80 attachment site is specifically promoted on infection by the φ80 transducing phage (iv) The presence of many copies of the structural gene for the su_{III} tyrosine *t*RNA specifically induces the expression of one class of chromosomal tyrosine *t*RNA genes

At present we cannot say which of these mechanisms produces the effect we have observed Experiments are in progress which should distinguish between them

Tyrosine *t*RNAs in Uninfected *E coli*

There are two principal tyrosine *t*RNAs in *E coli* which can be separated by column chromatography on DEAE 'Sephadex'[16] These are referred to as I and II in the order they elute from the column They are present in proportions of approximately 40 per cent (I) and 60 per cent (II) We have determined the sequences of I and II from *CA*265 su^+_{III} uniformly labelled with phosphorus-32 The labelled tyrosine *t*RNAs were isolated by a combination of chromatography on DEAE 'Sephadex', and either reversed phase partition chromatography[17] or chromatography on benzoylated DEAE cellulose[18] The sequences were derived in the same way as for su^+_{III} *t*RNA Certain overlaps of the complete T_1 and pancreatic digestion

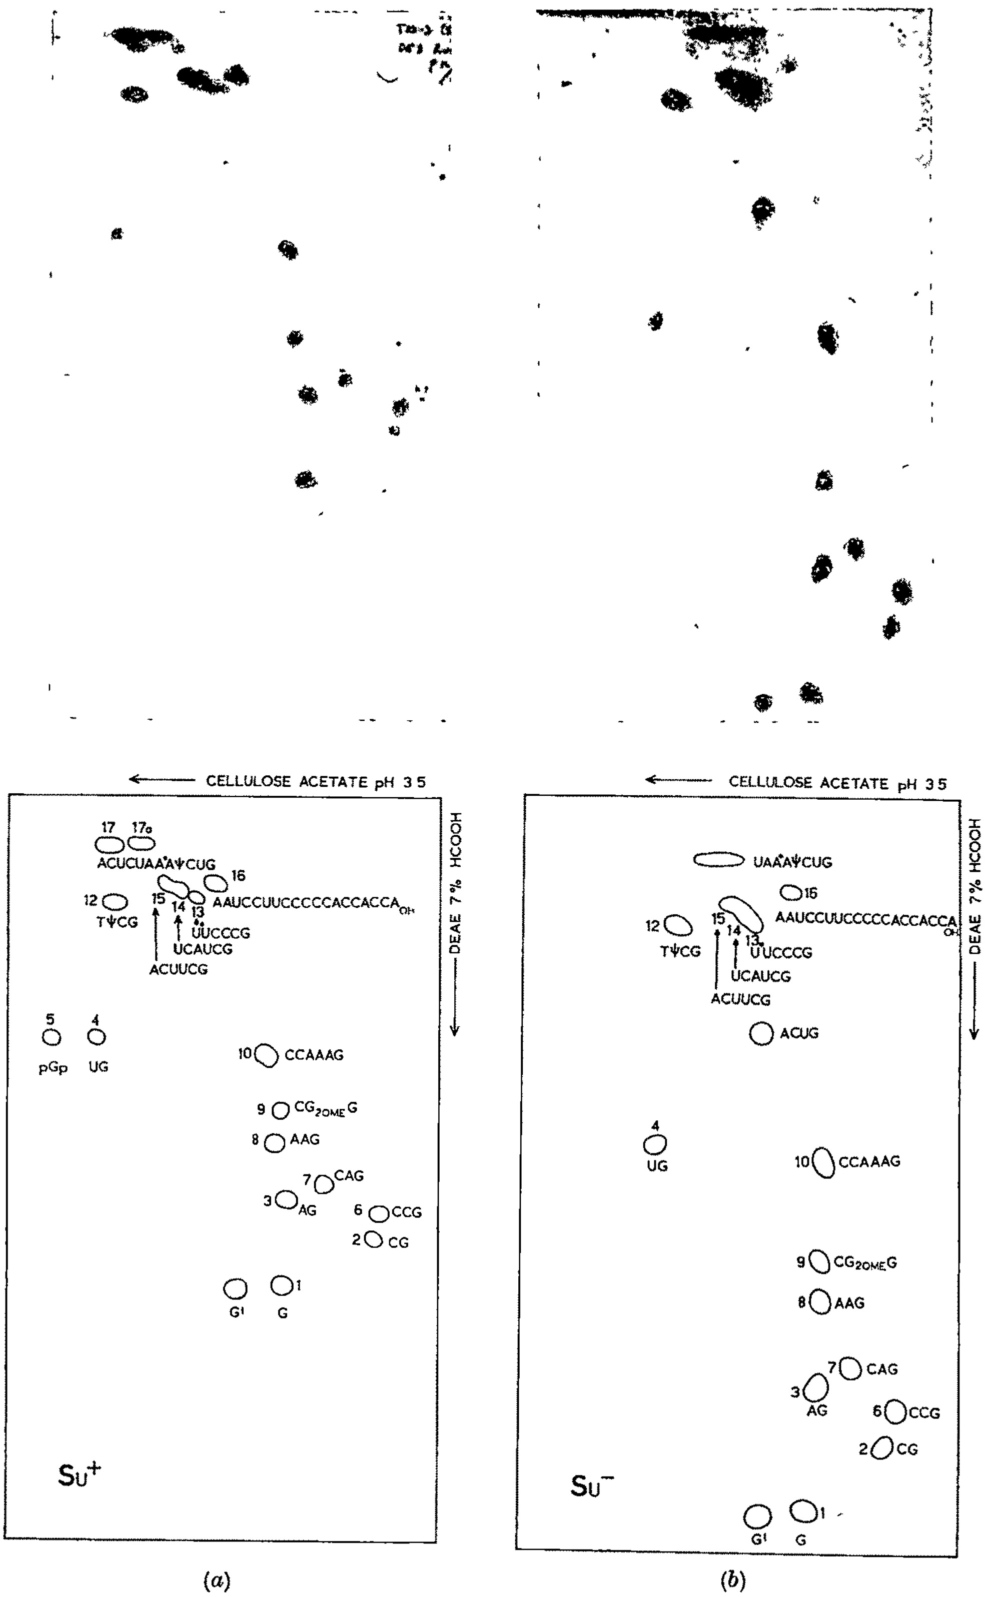

Fig 4 Two dimensional electrophoretic separation of a ribonuclease T_1 digest of su^+_{III} tyrosine *t*RNA labelled with ^{32}P. *a*, The end-products of ribonuclease T_1 digestion were separated by two dimensional electrophoresis first on cellulose acetate in pyridine–acetate buffer, *p*H 3.5, and then on DEAE–cellulose paper in 7 per cent formic acid (v/v). The lower diagram shows the identification of the nucleotides. The three hexanucleotides 13, 14 and 15 can be resolved after removal of their terminal 3′-phosphates with phosphomonoesterase. The appearance of CG is a consequence of incomplete 2′-*O*-methylation of $CG_{2'OMe}G$ giving rise to CG plus G after digestion with ribonuclease T_1. The hexanucleotide, U*UCCCG, always occurs in low yield, a fact that has not yet been adequately explained. pGp streaks badly and has partially migrated off the paper, making it difficult to detect. The two spots to the right and slightly above UG are minor contaminants which disappear on further purification of the *t*RNA. U* is a sulphur-containing nucleotide, tentatively identified as 4-thiouridylic acid. A* is derived from adenylic acid and, because it can be labelled with (^{35}S) sulphate and (^{14}C)-methyl methionine, it presumably contains both sulphur and a methyl group. *b*, Two dimensional electrophoretic separation of a T_1 ribonuclease digest of su^-_{III} tyrosine *t*RNA labelled with ^{32}P produced after infection with φ80 *dsu*$^-_{III}$. In this separation spot 16 has trailed but is normally present in molar yield. The time of electrophoresis on DEAE paper was longer than in *a*.

products in the first sixteen residues have not yet been obtained, and the sequence in this region is assigned by analogy with that of the su^{+}_{III} *t*RNA.

Both tyrosine *t*RNAs I and II contain the anticodon G*UA and differ only in a sequence of two nucleotides in the loop between the anticodon and TψCG arms (Fig. 3*a*). Tyrosine I has a sequence apparently identical with that of su^{-}_{III} tyrosine *t*RNA so that in *E. coli* there are only two basic types of tyrosine *t*RNA sequences.

Thus it is clear that the two different sequences (I and II) must be specified by separate genes. If tyrosine *t*RNA I and su^{-}_{III} were determined by the same gene, then we would expect that in an su^{+}_{III} strain all of tyrosine *t*RNA I would be converted to su^{+}_{III} *t*RNA. When tyrosine *t*RNA from *E. coli CA*275 su^{+}_{III} is fractionated on a DEAE 'Sephadex' column, assays for su^{+}_{III} *t*RNA show that it is located between the peaks of tyrosine *t*RNAs I and II (Fig. 5). This is confirmed by fingerprinting. We conclude that there is a separate gene for su^{-}_{III} *t*RNA even though it has the same sequence as tyrosine I.

Comparison between Yeast and *E. coli* Tyrosine tRNAs

It is interesting to compare the sequences of the yeast and *E. coli* tyrosine *t*RNAs. The shape and hydrogen bonding pattern of the clover leaf model are common to the two organisms. As indicated on the diagram, most of the specific sequence similarities between the two tyrosine *t*RNAs are also shared by all the other yeast *t*RNA structures[19–22], so that when these are taken into account the sequence differences between the two tyrosine *t*RNAs are very striking. An interesting feature is the complete absence of dihydro-uridylic acid (D) from the *E. coli* tyrosine *t*RNA. The greatest similarity is in the anticodon loop and the lower three base pairs of the anticodon arm, which, except for modified bases, are identical in the two *t*RNAs.

At this stage it is not useful to speculate which part of the structures serve as the amino-acyl synthetase recognition site. Neither yeast nor *E. coli* tyrosine *t*RNA can be acylated by the heterologous synthetase[23], so the two transfer RNAs may have quite different recognition sites.

Discussion

The mutation giving rise to the su^{+}_{III} gene changes the anticodon of a minor tyrosine *t*RNA species from GUA to CUA. This change enables the *t*RNA to recognize the amber codon UAG instead of the tyrosine codons UAU and UAC. It seems likely that the mutations leading to the su^{+}_{I} and su^{+}_{II} amber suppressor genes have similarly affected structural genes for serine and glutamine *t*RNA. These *t*RNAs could have anticodons related to the amber anticodon by a single base change.

The ochre suppressor gene su_{c} maps in the same position as the su_{III} gene[24] and also causes the insertion of tyrosine[25]. The su_{c} gene may therefore be another allele of the su_{III} gene. Amber suppressor genes may only arise where there are multiple genes for a particular *t*RNA species. In the case of tyrosine *t*RNA we have provided evidence that there are at least three structural genes. If there are no more than three genes our results suggest that the genes are expressed at different rates. We estimate that tyrosine *t*RNAs I, II and *su* are present in the approximate ratios 25:60:15. The need for this differential control is obscure because the three *t*RNAs have nearly identical sequences.

One might predict that multiple amber suppressor genes could arise corresponding to the multiple tyrosine *t*RNA genes. Perhaps not all of these could be obtained as the large amount of tyrosine II *t*RNA in the cell might make an amber suppressor mutant of this gene lethal. We have examined three independently isolated amber suppressor strains which insert tyrosine. All these map very close to the original su^{+}_{III}. In addition, Garen's *su*3 (ref. 26) and Yanofsky's *suYmel* (personal communication from G. Dennert and U. Henning) insert tyrosine and map in this region. These results suggest either that only one of the tyrosine *t*RNA genes can mutate to su^{+}_{III} or that at least two of the genes are located close to each other.

The G to C change in the nucleotide sequence of the *su* tyrosine *t*RNA specifically changes its codon recognition but does not affect any of the other functional properties of the *t*RNA. This formally designates this position as part of the anticodon and also shows that at least the first position of the anticodon is not necessary for recogni-

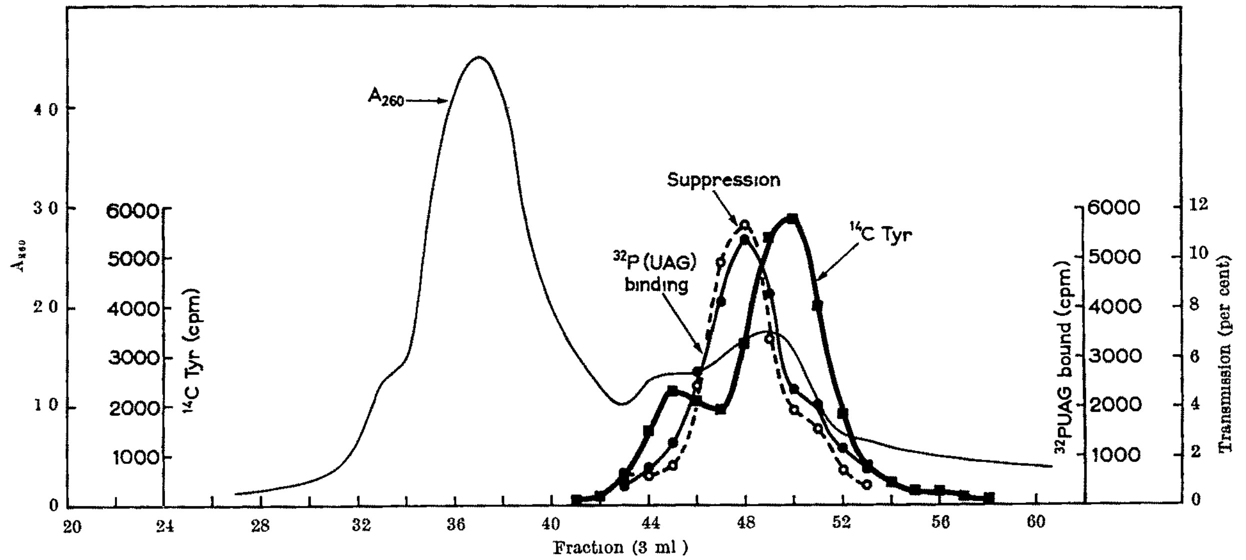

Fig. 5. Separation of the tyrosine *t*RNA components from *E. coli CA*275 su^{+}_{III} and identification of the su^{+}_{III} tyrosine *t*RNA. Tyrosine *t*RNA (from *CA*265 su^{+}_{III}) was purified approximately five-fold by chromatography on benzoylated DEAE cellulose. The figure shows the separation of this material by chromatography on a DEAE 'Sephadex' column (0.5 × 200 cm). Tyrosine *t*RNA elutes in two peaks, I and II (in order of elution). The suppressor *t*RNA was located by two methods. (i) fractions were tested for their ability to bind (^{32}P)pUpApG to ribosomes at 30 mM Mg^{++} using the Nirenberg and Leder assay[27]. (ii) Fractions were also tested for their ability to suppress *in vitro* the *sus* 3 amber mutation of the coat protein of the phage *f*2. This assay was performed by Dr Harvey Lodish using a modification[28] of the method of Engelhardt *et al.*[3]. The measure of suppression is the percentage of transmission, defined as the ratio of completed coat protein molecules/the total number of polypeptide chains initiated, at a concentration of 8 μg/ml. of suppressor *t*RNA added.

tion of amino-acyl synthetase To identify the function of other parts of the molecule, different mutants of this gene must be studied These can be obtained by isolating *su^-* revertants of the *su^+* gene Any mutation which gives rise to a non-functional *t*RNA will have the *su^-* phenotype Garen, Garen and Wilhelm[26] have isolated *su^-* revertants of the *su_{I}^+* gene These map in five closely linked sites indicating that different parts of the *su_{I}^+* gene may be mutated to give the *su^-* phenotype

With L Barnett we have isolated a number of *su^-* revertants of the *su_{III}^+* gene We are in the process of characterizing the structural and functional changes in the *su^-* tyrosine *t*RNA caused by these mutations This should provide insight into the structural basis for function in *t*RNA molecules

We thank Dr F Sanger, Dr G G Brownlee and Mr B G Barrell for their help Dr S Zadrazil helped to characterize the minor nucleotides We thank the Radiochemical Centre, Amersham, for preparing labelled *t*RNA and Mrs R Fishpool, Miss E Holgate and Mr G Chambers for technical assistance One of us (A L) was supported by US Public Health Service and American Cancer Society postdoctoral fellowships; another (J A) by a US Public Health Service postdoctoral fellowship, and another (H M G) by the Helen Hay Whitney Foundation

Erythropoietin and the Development of Erythrocytes

During the differentiation of erythrocytes some cells develop which contain a high concentration of haemoglobin and no cytoplasmic basophilia Erythropoietin has the effect of increasing the proportion of these cells in preparations of marrow Two of the communications which follow discuss the effect on these cells of erythropoietin and of ageing and haemorrhage The third communication describes a factor in the serum of a polycythaemic calf which enhances the activity of erythropoietin

Effect of Erythropoietin *in vitro* which Simulates that of a Massive Dose *in vivo*

IN smears of normal rabbit marrow a few erythroblasts can be seen which are of the same size as the haemocytoblasts, pronormoblasts and basophilic erythroblasts, with almost the same large ratio of nucleus to cytoplasm They differ, however, in that they have no cytoplasmic basophilia. The concentration of haemoglobin seems to be greater in these than in their basophilic counterparts The high ratio of nucleus to cytoplasm as well as the larger size distinguishes them from polychromatic and orthochromatic erythroblasts For convenience they are referred to as line 2 cells and the typical early basophilic erythroblasts are referred to as line 1 cells

It is well known that in the marrow of a severely anaemic animal there is, with the erythroid hyperplasia, a shift of the distribution towards the less mature erythroblasts In such animals the number of early line 1 cells and all line 2 cells are increased In the rabbit made severely anaemic by injections of phenylhydrazine, the ratio of line 2 line 1 is increased several times. Early line 2 cells are seen more often in some stage of cell division than any other class of erythroblasts Often their nuclei became pyknotic, indicating their early conversion to large non-nucleated erythroid cells—reticulocytes and erythrocytes

There are three possibilities regarding the origin of line 2 cells first, that they arise directly from the stem cell compartment, second, from early line 1 cells; or third, by both routes In the search for ways of obtaining direct evidence it was found that rabbit erythroblasts kept overnight in normal rabbit plasma at 5°–15° C seemed from their staining characteristics to be well preserved At higher temperatures many had degenerated When 10 U/ml of erythropoietin was added to the plasma, there was a significant increase in the number of early line 2 cells on the following day. Without the erythropoietin there was no increase

The following procedure was adopted to investigate the effect of erythropoietin in these conditions Rabbit marrow erythroblasts were fractionated in a buoyant density gradient of bovine serum albumin (unpublished work of Borsook, Gunderson and Teigler) Cell fractions, washed free of bovine serum albumin, were suspended in normal rabbit plasma which contained 50 mg per cent of sodium heparin and which had been heated at 56° C for 30 min and filtered Penicillin *G*, streptomycin sulphate, and tetracycline were added in the respective quantities, 0 2, 0 2 and 0 05 mg/ml Aliquots of 1 ml containing about 10^7 cells were transferred to 15 ml plastic beakers, covered with aluminium foil, and set on one side at 37 5° C for 1 h to prevent the growth of micro-organisms The materials the effects of which were to be tested were added after incubation at 37 5° C The cell suspensions in the covered beakers were set on one side at 10° C Better yields seemed to be obtained by keeping the suspensions still in an atmosphere of oxygen or air + 5 per cent carbon dioxide After 16–20 h the cells were removed and centrifuged, and smears were made of the pellet These were stained with benzidine and counterstained with Giemsa solution After 20 h at 10° C in these conditions the cells incorporated ^{14}C-2-glycine into haem and protein at 80 and 100 per cent of the respective initial rates

The phenomenon under investigation was the disappearance of cytoplasmic basophilia from the erythroblasts To describe the changes the following scoring system was used, based on the yellow colour that benzidine confers on haemoglobin clear yellow, 5, yellow with a few greenish areas, 4, greenish yellow, 3, one-quarter of the circumference of the cell deep green or blue, 2, one-half to three-quarters blue, 1, more than three-quarters blue, 0 The long diameter of the cell was measured with a micrometer in the eyepiece

Table 1 shows a representative effect of erythropoietin (EP) and calf serum erythropoietin enhancing factor (EH) (see communication by D Van Dyke, M L Nohr and B Tennant) on an erythroblast fraction from normal rabbit The distribution of scores of the different sized cells allowed them to be grouped into those with diameters 9μ or smaller and 10μ or larger, corresponding to those of normal polychromatic–orthochromatic erythroblasts and of the early haemocytoblast, pronormoblast, basophil group According to conventional classification, the cytoplasm of the one is acidophilic, the other basophilic. The cells scoring 0 in the 9μ or smaller group would be designated as small basophils, those scoring 3 or higher in the 10μ or larger group are the early line 2 cells Table 1 shows that EP+EH accelerated the disappearance of the cytoplasmic basophilia in both groups of cells, irrespective of whether the scores are expressed as an increase in average cell score, as a percentage of the total scoring 3 or higher, or as a decrease in the percentage scoring 0 In plasma alone the scores differed little from the initial values

Tables 2 and 3 summarize results from five experiments with similar erythroblast fractions from normal rabbits as used in Table 1. They show the range of variation observed in the response to EP+EH

The percentage of cells scoring 3 or higher in the experiments of Tables 1, 2 and 3 was greater than in the whole erythroblast population of the marrow because a selected fraction was used

Table 1 EFFECT OF ERYTHROPOIETIN *in vitro* AT 10° C ON THE DISAPPEARANCE OF CYTOPLASMIC BASOPHILIA IN ERYTHROBLASTS FROM NORMAL RABBITS

4	0 39	0 93	86	61	9	21
5	0 61	1 35	74	32	10	53

EP and EH as in Table 1

All the different gradient fractions of erythroblasts were examined from both normal and severely anaemic animals (by injection of phenylhydrazine), to find the group which would show the effect of EP+EH most clearly An accelerated disappearance of cytoplasmic basophilia in the presence of EP+EH was observed in all the cell fractions and in all cell size groups with diameters varying from 7μ to 17μ, whether from normal or severely anaemic rabbits

It is reasonable to surmise that the accelerated disappearance of cytoplasmic basophilia under the influence of erythropoietin is several times faster *in vivo* than at 10° C *in vitro* Because basophilic erythroblasts of all sizes respond, the *in vivo* response must be of considerable magnitude

Tables 4 and 5 summarize observations on the effects of actinomycin *D* on the accelerated loss of cytoplasmic basophilia Only the results in the size group 10μ or larger are given, but they are similar to those found in the smaller cells It can be seen that actinomycin *D* can completely nullify the effects of EH + EP The effects of EH and EP, separately and together, are similar to those observed by Van Dyke *et al* (see p 1027) on uptake of ^{59}Fe after injection into mice The competitive counteraction of erythropoietin and actinomycin *D* has also been observed *in vivo*[1]

Some exploratory experiments were carried out on the effect of EP+EH on the ability to synthesize haem and protein Cells exposed to EP+EH incorporated 20–25 per cent more ^{14}C-2-glycine into the haem and total protein

These observations show that erythropoietin also acts on cells peripheral to the stem cell compartment They explain the quick response *in vivo* to a large dose of erythropoietin that is, the appearance in the blood of abnormally large cells more quickly than can be accounted for as coming from the stem cell compartment They also offer an explanation for the possible mechanism involved in the earlier observations of Gallagher *et al* [2] on the effect of erythropoietin on nucleated red cells

The loss of cytoplasmic basophilia is the terminal differentiation in erythropoiesis[3,4] and is concomitant with a considerable biochemical change Haemoglobin synthesis becomes 85–90 per cent instead of 20 per cent of the total protein synthesis, and it is the principal, whereas earlier it is an acidic minor, haemoglobin, that is chiefly synthesized[4,5] This terminal differentiation is inhibited by actinomycin *D* For example, when 100 μg/kg of actinomycin *D* is injected into a rabbit, in 4 days all acidophilic erythroblasts and reticulocytes disappear from the marrow Haemocytoblasts, pronormoblasts and baso-

Table 4 EFFECTS OF EH ON EP AND OF ACTINOMYCIN *D* ON EH+EP IN ERYTHROBLASTS FROM NORMAL ANIMALS

Additive to normal plasma	Average cell score	Percentage of total cells scoring 3 or higher

EP alone	2 00	35
EP+EH	2 60	57
EP+EH+actinomycin *D* (0 7 μg/ml)	2 12	46
EP+EH+actinomycin *D* (3 5 μg/ml)	1 40	24

EP and EH as in Table 1

philic erythroblasts, however, are present in normal amounts (results to be published) Tables 4 and 5 show the same effect *in vitro*

The phenomenon described causes a quick increase in circulating erythrocytes by accelerated maturation and possibly by skipping some divisions[6] Because erythropoietin certainly causes differentiation of stem cells into erythroid cells[7], there seem to be two "sites" at which it can act on an undifferentiated stem cell population in which it can induce differentiation, and on already differentiated basophilic erythroblasts increasing their rate of maturation

We thank Dr Donald C Van Dyke for the erythropoietin and its assay, and for the calf serum erythropoietin enhancing factor we have used This work was supported by grants from the US Public Health Service, the Atomic Energy Commission and by an NASA grant to the University of California, Berkeley

Emergence of Two Erythroblast Lines in Erythropoiesis during Growth and Haemorrhage in the Rat

DURING studies of erythropoiesis in rats of different age groups and in rats which had been heavily bled, line 1 and line 2 normoblast cells, as described in the preceding communication, appeared in varying numbers Consequently, the proportion of line 1 and line 2 cells present in the bone marrows and spleens of these animals has been examined

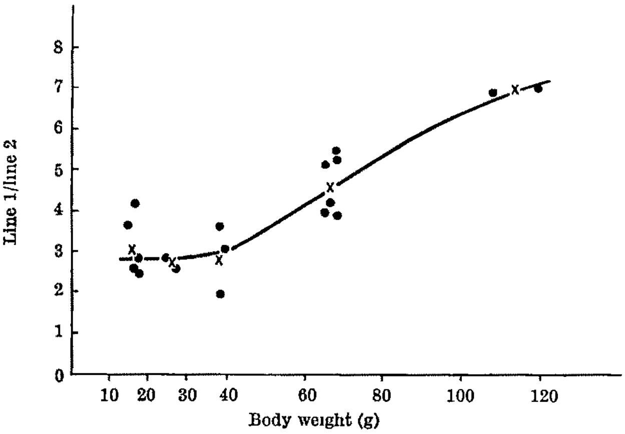

Fig 1 Variation in the ratio of line 1 to line 2 erythroid cells in the bone marrow of rats during the first 8 weeks of life

Using groups of August rats weighing approximately 15 g (7–10 days old), 25, 40, 65 and 110 g (6–8 weeks old), smears of spleen and femoral marrow were made and differential counts of early and intermediate normoblasts with the usual degrees of cytoplasmic basophilia or with the high haemoglobin content—line 1 and line 2 normoblasts—were obtained Omitting the late normoblasts which, by definition, have a high degree of haemoglobinization and therefore cannot with confidence be described as line 1 or line 2, the ratio of the numbers of line 1 to line 2 normoblasts was calculated The results for the bone marrow are shown in Fig 1

Up to 40 g (3 weeks old) the ratio is about 3 1, after which the proportion of line 2 normoblasts gradually declines until in the adult animal the ratio is about 7 1 Thus it would seem that the line 2 normoblasts are associated with the high rate of production of erythrocytes necessary during the early growth period when the blood volume is expanding rapidly The curve also probably corresponds to earlier work[1] in which it was shown that a high degree of cell proliferation in the bone marrow remains constant up to about 40 g body weight, after which it declines

In the second series of experiments, adult rats were bled approximately 10 per cent of their blood volume by cardiac puncture and were killed after 48 h Spleen and marrow smears were made and differential counts of normoblasts were made Table 1 summarizes the ratios of line 1 to line 2 normoblasts, again omitting the late normoblasts

Table 1 shows that bleeding the animal causes an increase in the proportion of line 2 cells in the marrow with the result that the picture becomes similar to that in the 1 week old rats In the spleen, also, the ratio of line 2 to line 1 normoblasts is very similar in the bled adult rats and the 1 week old rats In the case of this organ, however, comparisons are difficult because of the almost complete absence of normoblasts in the adult rat spleen Consequently, this increase in line 2 cells is a real increase in the absolute number of line 2 cells, probably resulting from stimulation of the stem cells

In the marrow of the bled rats, the origin of the line 2 cells was not so clear Identification of many of the line 2

Table 1 RATIO OF LINE 1 TO LINE 2 ERYTHROID CELLS IN THE BONE MARROW AND SPLEEN OF RATS OF DIFFERENT AGES AND FOLLOWING HAEMORRHAGE IN THE ADULT RAT

Ratio of $\frac{\text{line 1}}{\text{line 2}}$	Bone marrow	Spleen
1 week old	3	1 2
7 weeks old	7	—
Bled adult	2 2	1 3

cells was not so positive and a number of cells classified as line 2 should, on morphological grounds, more properly have been put in a group between the two lines The appearance was therefore that the line 1 cells were passing through a transitional stage into the line 2 cells This type of change would agree with the observation, described in the preceding communication, that transformation from line 1 to line 2 cells was stimulated *in vitro* with erythropoietin

In summary, in the 1 week old rat there is a high proportion of line 2 normoblasts present in the nucleated erythroid cell populations of both bone marrow and spleen During growth, the proportion of line 2 cells gradually decreases When the adult animal experiences a severe haemorrhage, line 2 cells appear in large numbers at both sites In the marrow, part of the increase may be caused by stimulation of the stem cell compartment, but part also seems to be the result of a transition from the early line 1 to early line 2 cells In the spleen, the appearance of large numbers of line 2 cells is probably a result only of a stimulation of the stem cell compartment Thus the differentiation step to major haemoglobin production can take place at either the stem cell or the committed erythroid cell level

Erythropoietin Enhancing Factor in Serum of a Calf with Primary Familial Polycythaemia

PRIMARY familial polycythaemia occurs occasionally in calves of an inbred Jersey herd maintained at the University of California, Davis The genetic pattern of this disease suggests a simple autosomal recessive mode of inheritance[1] During investigation of the aetiology of this disease, it was discovered that serum from the one currently surviving calf with polycythaemia, although itself devoid of measurable erythropoietic activity, when incubated with erythropoietin resulted in a four-fold enhancement of activity Incubation with normal calf serum did not enhance the activity of erythropoietin in the assay system employed in these studies

Gardner *et al*[2] have reported enhancement of purified erythropoietin by serum from normal human beings, normal rabbits and normal mice Although in these studies serum from normal calves consistently failed to enhance erythropoietin activity, incubation of erythropoietin with sera from other species, dog, monkey and man, was found to increase erythropoietin activity 1 5–2 3-fold

Serum was obtained from the 6 month old female calf with familial primary polycythaemia and from four normal Jersey female calves of the same age in the herd All sera were frozen immediately after separation and stored until use The haematocrit of the polycythaemic calf was 65 per cent, haemoglobin was 21 g/100 ml The haematocrit of the normal calves was 31, 34, 39 5 and 39 per cent, haemoglobin was 11 7 and 10 8 g/100 ml (calves *C* and *D* were not measured)

Erythropoietic activity was assayed in hypertransfused female *BALB/c* mice, according to the method of DeGowin *et al*[3] Erythropoietin was obtained from the urine of a patient with aplastic anaemia[4] and concentrated by collodion adsorption[5] This erythropoietin was standardized by comparison with the International Reference Preparation[6], using either saline or serum as diluent

All sera were incubated with erythropoietin for 2 days in the cold (8° C) Erythropoietin alone and serum alone were also incubated in the same conditions

Table 1 shows the enhancement of erythropoietin after incubation with various amounts of polycythaemic calf serum Serum obtained before the calf was 8 5 months old produced a consistent and significant enhancement of activity of erythropoietin even with as little as 0 1 ml of polycythaemic calf serum No enhancement of activity occurred in the case of incubation with serum from normal calves When this experiment was repeated with serum collected a fortnight later, identical results were obtained, 1 ml of serum gave a four-fold enhancement of erythropoietin activity Table 1 also shows the results of simultaneous subcutaneous injections of erythropoietin and polycythaemic calf serum at different sites, significant enhancement was not observed.

Table 1 ERYTHROPOIETIN ENHANCING FACTOR IN SERUM OF A POLYCYTHAEMIC CALF

Group (No of mice)	Activity (× ESF control)	Significance of difference*
Polycythaemic calf		
1 ml of serum + ESF (6)	4 0	0 001
0 5 ml of serum + ESF (10)	3 0	0 001
0 1 ml of serum + ESF (10)	2 4	0 001
1 ml of serum and ESF at two sites (7)	1 8	0 1
Normal calves 1 ml of serum + ESF		
Calf *A* (6)	0 7	0 02
Calf *B* (9)	0 7	0 001
Calf *C* (8)	1 0	—
Calf *D* (9)	1 4	0 3

ESF, erythropoietic serum factor

* Fisher's *t* test

These findings indicate that the serum of this polycythaemic calf contained something not present in norma calf serum which in itself had no erythropoietic effect but which on incubation with erythropoietin resulted in four-fold enhancement of the activity Spontaneous recovery has been observed in affected calves which survive for more than one year, and in an attempt to ensure survival of this calf until remission occurred, phlebotomies were carried out at approximately monthly intervals Erythropoietin enhancing activity was assayed in serum from successive bleedings and a decrease in activity at 8 5 months with complete disappearance of enhancing activity by 10 months was revealed (Table 2) Although it seemed reasonable to assume that this factor was causally related to the polycythaemia in this calf and to the severe and often fatal polycythaemia occurring in other calves of this herd, we found no remission in polycythaemia corresponding to, or within 4 months of, the disappearance of the detectable level in the serum

Table 2 DECREASE IN ERYTHROPOIETIN ENHANCING FACTOR WITH AGE OF POLYCYTHAEMIC CALF

Age (months)	Haematocrit (%)	Activity (× ESF control) 1 ml	0 5 ml	0 1 ml
5 3	66	2 9	2 4	2 4
6 4	64 5	4 0	3 0	2 4
7 2	66	4 2	3 7	3 9
8 5	69	1 6	1 9*	
9 5	67	1 0	1 0	
10 0	70	0 6		

* Average of ten assays, one of which was negative

Enhancement of erythropoietin by incubation with renal erythropoietic factor (REF)[7] suggested that the enhancing factor present in this calf might be REF Further investigation of the physiological and chemical characteristics of the enhancing factor in the intact mouse assay system being employed, which requires relatively large amounts of material, was not possible The small remaining supply of active serum (from bleedings at 6 and 7 months) was reserved for study in the *in vitro* system described in the first of these three communications Further investigation of this subject must await birth of another calf afflicted with primary familial polycythaemia

The structures of two new phases of divalent cation soaps have been solved The polar groups (cations and carboxyl groups) form planar two-dimensional networks, either square or hexagonal, embedded in a continuous matrix formed by the disordered paraffin chains. These and earlier results make possible a unified picture of a novel class of structures in all of which the polar groups are clustered in rod-like regions, but which differ in the way the rods are arranged in one, two or three-dimensional networks.

THE work described here arose from the casual observation of striking structural analogies between the high-lipid, high-temperature phases of lecithin–water systems and the anhydrous high-temperature phases of several divalent cation soaps This observation has led to an analysis of the literature, to the reinterpretation of some of the published data, and in some cases to new experiments The result has been the discovery of a novel family of structures, formed by identical rod-like elements, which are ordered into either two or three-dimensional lattices The "structure elements", to which we often refer in this article, are by definition the locus of the polar groups, those elements are embedded in a paraffin matrix in which the electron density is supposed to be uniform throughout The structures observed with soaps are described here the lecithins will be discussed later

Spegt and Skoulios studied many anhydrous soaps of the divalent cations of group II as a function of temperature, using X-ray diffraction techniques[1-4]. Many of the data used here come from that work when new experiments were carried out, the techniques were those described by Spegt and Skoulios. A few examples of the phase diagrams established by these authors are given in Table 1 The low-temperature phases C_1 and C_2 are lamellar, with stiff paraffin chains; the conformation of the chains in all the other phases is disordered, as shown[5] by the presence of a diffuse band near $s=(2 \sin \theta/\lambda)=(4\ 5\ \text{Å})^{-1}$ Phases H, T, R, Q are each characterized by a number of sharp small-angle reflexions Phases H, H_1 and H_2 are two-dimensional hexagonal arrays of rigid rods, the rods containing the polar groups of the soaps Spegt and Skoulios have shown that the number n of cations per unit length of rod, a parameter easily determined for this type of structure, is constant for all the soaps of the same cation[1-4]. When two hexagonal phases (H_1 and H_2) are observed in one soap, each phase is characterized by a different value of n (refs 1 and 4) Phase Q is body-centred cubic[3]; its structure[6] consists of rods of finite length, linked three by three, and forming two interwoven three-dimensional networks (ref 6, Fig 2) The distribution of the cations seems to be uniform along the rods, with the exception of a short gap (approximately 1·5 Å long), devoid of cations, near the ends In this structure the number n is the same for all the strontium soaps; furthermore, n is almost identical in phases Q and H (ref. 6 and Table 2)

Here we are mainly concerned with the structure of phases T and R Spegt and Skoulios have indexed the small-angle reflexions of both phases on two equatorial planes, assuming arbitrarily that the two planes are at right angles they propose a face-centred orthorhombic lattice for phase T (ref 2), and a face-centred monoclinic lattice for phase R (ref 3) In fact, an inspection of the data shows that for all the soaps and at all temperatures the spacings of the reflexions are in perfect agreement with a body-centred tetragonal lattice for phase T ($a/c=\sqrt{2}$ in Tables 3 and 4 of ref 2), and with a rhombohedral lattice

Table 1 PHASE DIAGRAMS OF THE ANHYDROUS STEARATES OF THE CATIONS OF GROUP II

Mg^1	C_1 or C_2 (109°) H_1 (195°) H_2 (210°) melt
Ca^2	C_1 (100°) C_2 (123°) T (152°) (179°) H (>350°)
Zn^1	C_1 (130°) melt
Sr^3	C_1 (130°) (170°) R (197°) Q (246°) H (>400°)
Cd^4	C_1 (99°) H_1 (211°) H_2 (~230°) melt
Ba^1	C_1 (150°) (220°) Q (>400°)

Transition temperatures are given in parentheses The dotted lines show regions in which the phases have not been fully characterized The phase diagrams of the other saturated soaps of the same cation are quite similar to stearate (see refs), although the phase T was observed recently in strontium arachidate, near 170° C (unpublished results) The correspondence of the nomenclature adopted here with that of Spegt and Skoulios is the following for the calcium soaps T and H replace D and F, for the strontium soaps R replaces Δ, for the cadmium soaps H_1 and H_2 replace B and C

The structures of phases R and Q are shown in Fig 1 and in ref 6, Fig 2 The parameters a and c of the hexagonal cell were deduced from the parameters c', b' and γ' of the face-centred monoclinic cell of ref 3 ($a=2c'$, $c=3/2\, b' \sin \gamma'$), and were verified with new experiments (The density δ is determined as in ref 6, Table 2) $N=0\ 602\ V\delta/M$ is the number of cations associated with one lattice point (V, volume of the elementary cell, M, molecular weight of the soap) The symbol n is the number of cations per unit length of rod $n=N/3(D-d)$, where $D=a/\sqrt{3}$ is the length of one side of the hexagon, $d/2=1\ 56$ Å is the length of the gap devoid of cations, at each end of the rods The dimensions of phases Q and H are taken from refs 3 and 6

* See comment in Table 1

Table 3 SOME DATA ON THE CALCIUM SOAPS

The structure of phase T is shown in Fig 2 The parameters a and c are taken from ref 2, Table 4 (c here is b in ref 2), and were verified with new experiments N is determined as in Table 2, with δ given in ref 2 $n=\frac{N}{2(D-d)}$, $D=a$, $d/2=3$ Å The lattices are pseudo-hexagonal ($c=\sqrt{3}\ a$) at the temperature of Table 3 The data of ref 2 permit calculation of N and n at different temperature, for calcium myristate the results are the same as in the table The value n of phase H is taken from ref 2

for phase R ($a/c=\sqrt{3}$ and $\cos\gamma\simeq a/3b$ in Table 3 of ref 3), these lattices will be adopted here, on the ground that the number of independent parameters is minimal (two for the tetragonal and rhombohedral, instead of three for the orthorhombic and four for the monoclinic) The agreement of the observed and calculated spacings is shown in Tables 4 and 5

By analogy with phases H and Q we propose that phases T and R are ordered arrangements of identical rod-like elements of finite length The structures are represented in Figs 1 and 2 the rods are linked together four by four in phase T, three by three in phase R, and form planar two-dimensional networks, either square or hexagonal These structures explain the observations in a far more satisfactory manner than the structures formed by disk-shaped structure elements, as suggested before (ref 2, Fig 5)

Observed and calculated intensities agree very well for the rod-like structures of Figs 1 and 2 (Tables 4 and 5), if, as in phase Q of the strontium soaps[6], the distribution of the cations is uniform along the rods*, with the exception of a short gap at the ends, devoid of cations It should be noted, nevertheless, that for disk-shaped structure elements the agreement would not be much worse, as long as the size and shape of the disks are properly adjusted, different soaps of the same cation should be compared if the intensity distribution were to provide a discrimination between rods and disks (this problem will be discussed elsewhere)

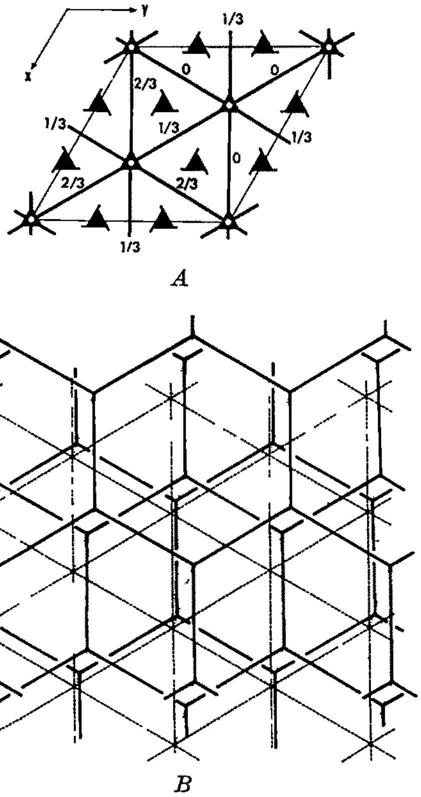

Fig 1 Phase R space group $R\bar{3}m$ The loci of the polar groups, represented by heavy lines, are rods of finite length that sit on mirror planes The rods are linked three by three, forming planar two-dimensional networks A, Projection of one unit cell along the hexagonal axis, with the position of some of the symmetry elements The rods are perpendicular to the c axis the fractional figures are the z co-ordinates of the rods B, Perspective view Note the two-dimensional hexagonal networks stacked and mutually unconnected

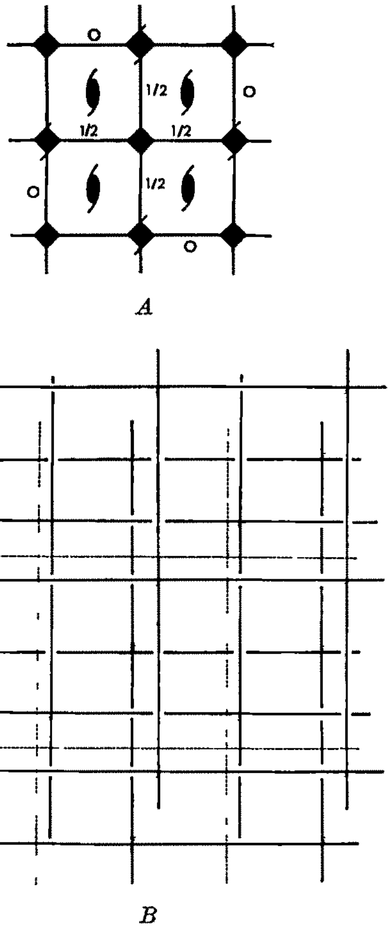

Fig 2 Phase T space group $I422$ (see legend of Fig 1) The polar groups sit on two-fold axes A, Projection of one unit cell along the tetragonal axis c The rods are parallel to the plane a, b, the fractional figures are the z co-ordinates of the rods B, Perspective view Note that the structure is formed by identical rod-like elements, linked four by four, forming two dimensional planar square networks The networks are stacked, otherwise unconnected

More direct arguments in favour of the rod-like structures can be obtained from analysis of the dimensions of the structure elements Tables 2 and 3 show the following (a) In each phase (T, R, Q, H) n is constant for all the soaps of the same cation (b) In the strontium soaps n has almost the same value in the three phases R, Q and H, the small differences between the phases T and H of the calcium soaps are of the same order as those observed between the phases H_1 and H_2 of the magnesium and cadmium soaps[1,4], and can be similarly explained, as discussed here (c) At high temperature, the lattices of phase T of all the calcium soaps become pseudo-hexagonal[2] (Table 3), a consequence of the fact that each of the bundles of rods parallel either to the a or to the b axis becomes a two-dimensional hexagonal array

Clearly all these numerical coincidences would be meaningless if the structure elements were assumed to

---

* The uniform distribution of the cations must be taken as a simplification justified by the low resolution of the X-ray data ($s^{-1}>8$ Å, see Tables 4 and 5

Table 4 X-RAY DIFFRACTION DATA OF PHASE *R* STRONTIUM MYRISTATE, 185° C

300	—	112 5	<10	<1	−9 5
027	—	112 5	<10	<1	+15 9

The X-ray pictures were recorded on a Guinier camera The values s_{obs} and s_{cal} are the reciprocal spacing ($s=2 \sin \theta/\lambda$) of the observed reflexions, and calculated for the hexagonal lattice (space group $R\bar{3}m$), with $a=30\ 8$ Å, $c=83\ 3$ Å Values of I_{obs} are the observed intensities, strong intensities were measured on densitometer tracings, and weak ones were estimated visually by recording the X-ray pictures on packs of films and comparing different films (the absorption coefficient of which is known) The intensities were corrected for the proper geometric factor The calculated intensities can be expressed as follows

$$I_{\text{calc}} = m\ F^2 \exp\left[-\alpha s_l^2 - \beta\,(s^2 - s_l^2)\right]$$

m is the multiplicity factor, F is the structure factor, normalized to $F_{000}=3(D-d)$ (that is, the total length of rods in one elementary cell), the gaussian function (s_l is the l component of s) takes into account several effects, such as the anisotropic thermal motion, the spread of the electron density around the axis of the rods, the scattering of the length of the rods (in Tables 2 and 3 n is not an integer) The structure factors are those of space group $R\bar{3}m$, special positions (x, $x/2$, $2/3$, and so on), integrated over the length of the rods (ref 10, page 472), the gap at the end of the rods is taken into account in the form of a delta function, at (0, 0, 2/3)

$$F_{hkl} = D/4 \int_0^{1/3} A_{hkl}\,(x,\ x/2,\ 2/3)\,\mathrm{d}x - 3d$$

The result is $F_{00l} = 3\,(D-d)$, $F_{hkl}=D-d$, $F_{hkl}=3D/\pi\,[(2h+k)^{-1} + (k-h)^{-1} - (h+2k)^{-1}] \sin 2\pi l/3 - 3d \cos 2\pi l/3$ The parameters used in the calculations are $D=17\ 8$ Å, $d=3\ 12$ Å, $\alpha=310$ Å^2, $\beta=680$ Å^2

Experiments and calculations were carried out according to the legend of Table 4 Space group $I422$, $a=35\ 2$ Å, $c=64\ 7$ Å The structure factors take the form $F_{00l}=2(D-d)$, $F_{h0l}=D-2d$, $F_{hkl}=\ -2d$ The parameters are $D=35\ 2$ Å, $d=6$ Å, $\alpha=490$ Å^2, $\beta=810$ Å^2

be disk-shaped, furthermore, the number of cations per disk (N in Tables 2 and 3) would vary with the length of the paraffin chain, and the high temperature form of phase T would be an odd pseudo-hexagonal organization of flat disks parallel to the "six-fold" axis

Other properties are consistent with the rod-like structures Fairly large crystals are observed in phase Q much more frequently than in any other phase this property should be correlated with the presence of the three-dimensional network Phases R and T can be visualized as lamellar structures, with stronger cohesion in the plane of the lamellae than between lamellae, and can be expected to display order–disorder phenomena whenever the interlamellar correlations become sufficiently loose Spegt and Skoulios[1–3] mention phenomena of that nature, characterized by the presence of both sharp and diffuse small-angle reflexions (these phenomena will be discussed elsewhere)

The most satisfying result emerging from the variety of structures described here is perhaps that one can construct a unified picture embodying them all Indeed, it is now clear that the high temperature phases of the anhydrous soaps of the divalent cations of group II are all constructed according to the same principle The polar groups are clustered in rod-like regions, and the rods, all identical and crystallographically equivalent, are organized in either a two or three-dimensional lattice Structure H consists of infinitely long isolated rods (one-dimensional network) arranged in a hexagonal two-dimensional lattice, structures R and T consist of rods of finite length, linked three by three or four by four, respectively, forming two-dimensional hexagonal or rectangular networks, which are stacked regularly into three-dimensional lattices Structure Q consists of rods joining three by three, and forming two interwoven three-dimensional networks This class of structures has been discussed by Wells[7], all the structures discussed in this article were considered by him

It is appropriate, in the context of this work, to mention another class of structures, originally described by Skoulios and Luzzati[8], that displays interesting analogies with the rod-like class In this class of structures the elements are lamellar the lamellae may be in the form of infinite planar sheets packed in one-dimensional (smectic) lattice[8], infinitely long ribbons organized in two-dimensional centred-rectangular[8] or oblique[9] lattices or, finally, disks organized in three-dimensional lattices[8] It is remarkable that all the high temperature phases of each of the anhydrous soaps studied so far belong to one or other of the two classes according to the nature of the cation rod-like for the cations of group II, lamellar for sodium[8], potassium[9], lithium[9] The highly developed organization of all these phases is achieved in spite of a great disorder of the paraffin chains, it is thus clear that the correlation between the chemical composition of the lipid and the class of the structures must be sought in the organization of the polar groups Although little direct evidence is available on this question, various indirect arguments suggest that the degree of order is quite high the fact that for different soaps of the same cation the number of molecules per unit length of rod (this work) or of ribbon[5] is constant clearly points to an ordered organization of the polar regions, the occurrence of two hexagonal phases in the magnesium and cadmium soaps is interpreted by Spegt and Skoulios[4] as a consequence of a polymorphic transition between two ordered arrangements of the polar groups The finite length of the rods, and the finite width of the ribbons and of the disks, can best be explained by the interplay of some ordered arrangement of the polar groups and of a disordered conformation of the paraffin chains (see discussion in refs 6 and 8)

We thank Dr A Klug for help with the manuscript This work was supported in part by grants from the Délégation Générale à la Recherche Scientifique et Technique, Comité de Biologie Moléculaire, and from the Direction des Recherches et Moyens d'Essais, Ministère des Armées

LETTERS TO THE EDITOR

PLANETARY SCIENCE

Holocene Earth Movements and Eustatic Sea Level Change in the Peloponnese

TWENTY-THREE archaeological sites on the east and south-east coast of the Peloponnese have been studied to determine the relative change of sea level at each site and the date of the latest occupation One site was uplifted, one undisplaced, seventeen submerged and four unproved (Fig 1 and Table 1) The displaced sites were at widely differing depths, and there was no simple correlation between age and depth, or location and depth It has been widely supposed, though on no certain evidence, that the Peloponnese is tilting downwards as a semi-rigid block to the south, about a hinge-line at the Gulf of Corinth, but the evidence does not support this

The displacement, approximate age to the nearest half millennium, rate of displacement and other data for each site are shown in Table 1 Displacement and age data are available for the western Mediterranean[1] based on fifty-four proved sites, and the distribution curves for the two areas are plotted in Fig 2

The curve for the western Mediterranean is markedly skew, because the data are effectively drawn from two populations Most sites are on stable lengths of coast such as that from Gibraltar to Toulon, while others are grouped in volcanic areas such as the Bay of Naples and round Etna where there is high seismic activity[2] The data for the Peloponnese come from an area which is uniformly seismically active[2] and show a random distribution of sites vertically

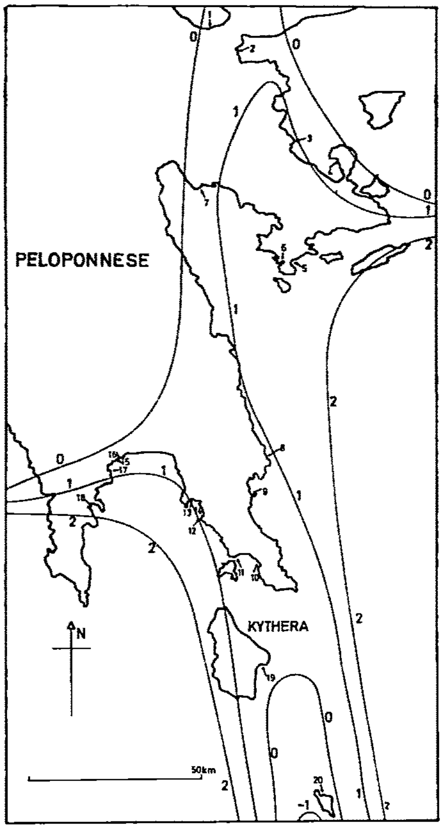

Fig 1 The coast of the eastern Peloponnese, southern Greece, showing the sites which produced definite data The contours indicate the best fit third order surface for the rate of displacement of each site in m/millennium downwards relative to present sea level

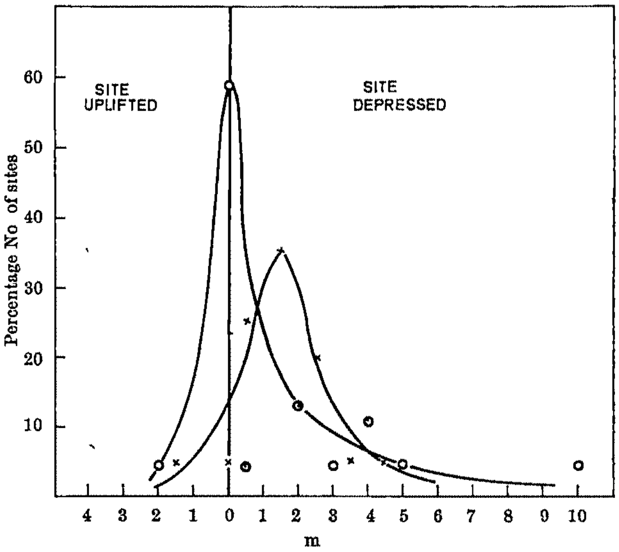

Fig 2 Percentage frequency of occurrence of archaeological sites plotted against magnitude of displacement during 2,000 yr, relative to present sea level O, Western Mediterranean, ×, Peloponnese

The Peloponnese data alone suggest a eustatic change of sea level equivalent to the mean displacement of sites, superimposed on a random tectonic displacement which was equally likely to be up or down at each site Other authors working from less complete field data have either stressed the tectonic factor alone[3] or the eustatic factor alone[4]

Evidence from the Atlantic coasts of Europe and America indicates that net eustatic change of sea level during the past 2 millennia has been less than 2 m (refs 5 and 6) and possibly less than 1 m (ref 7) The evidence from the western Mediterranean[1] shows that undisplaced sites occur in non-seismic areas, and that, to within an accuracy of observation of ± 0 5 m, the net eustatic change over 2,000 years has been zero, though sea level may have varied by 0 5–1 0 m in the interval Blackman (personal communication) has archaeological data showing that several sites on the Aegean coast of Turkey are also undisplaced

The Peloponnese data were tested statistically to look for a eustatic factor No correlation could be found with any of the proposed eustatic curves for the last 3,000 yr (refs 5–9) It was considered that rate of displacement might be related to geographical location, seismicity or isostatic gravity anomaly The number of epicentres published[2] and the accuracy of location of epicentres are

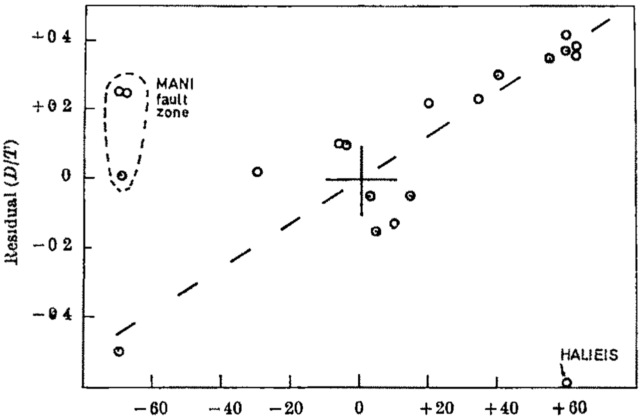

Fig. 3. The difference between the actual rate of displacement at each site and the predicted value from the computed surface is plotted against local Bouger gravity anomaly. Data from the areas of maximum faulting plot off the main trend. There are more points above the indicated mean than below because three values were originally minimum estimates and have been weighted towards the most probable value

not adequate to obtain a correlation. Gravity data were obtained from unpublished gravity maps of the eastern Mediterranean from the NATO SACLANT laboratory at La Spezia. There is no Bouger correction to apply at the shoreline, and the isogams of isostatic anomaly published by De Bruyn[10] follow the same general trend as the Bouger isogams available. It is the relative difference of value between sites which is significant, and there are insufficient data to construct more accurate isostatic maps, so that the Bouger data were used in the following calculations.

In order to isolate a possible eustatic factor the depth of each site was correlated with its age and local gravity anomaly, and then with the age and gravity gradient. Correlation in both cases was low (mean square residual (δ) = 0.365 and 0.503, respectively), and there was no time-dependent term which could be attributed to eustatic change.

If tectonic movements have been random in time, infrequent and of relatively large amplitude at time of movement, there would be no correlation between age and total displacement of a site. And if the period of study is sufficiently long for most sites to be displaced once, then there would be a correlation between magnitude of displacement and tectonic factors independent of time. This was tested by correlating depth with geographical co-ordinates, then with gravity anomaly and then with gravity gradient. All tests yielded very low correlation (δ = 0.495, 2.03, 1.72, respectively). This suggests that tectonic processes are continuous or at shortly spaced intervals compared with the period of the study. Correlation of the rate of displacement, however, in metres per millennium with the local gravity anomaly also produced low correlation (δ = 0.450).

Rate of displacement was correlated with geographical co-ordinates, and a third order equation produced a good fit (δ = 0.082, maximum residual = 0.59). The contours of this surface are plotted in Fig. 1. The close spaced contours to the south-west, indicating maximum variation in rate of displacement, coincide with a heavily faulted zone intersecting the coast between Skutari and Scala[11]. The close spaced contours to the north-east are probably an artificial effect caused by the absence of data further to the north-east, and the fact that the value for Methane is an open-ended minimum estimate, added to the real difference in values obtained at Halieis and Lorenzon.

The most notable feature of the contour pattern is the trend of the zero-displacement line to the north-west which indicates a doming of the Peloponnese with depression of the coastline about a hinge-line set back from the mean coastline. An uplifted ridge stretches south-east from the Elos peninsula through Kythera and Antikythera towards Crete, while a trough of depression extends into the Gulf of Argolis.

Fig. 3 shows a plot of the residual displacement—that is, the difference between the actual measured rate of displacement and that predicted by the equation—against local Bouger gravity anomaly. Allowing for the sites from the areas of maximum variation in rate of displacement caused by faulting, there is a positive correlation between high gravity anomaly and excessive displacement downwards. Thus, if the contours represent the mean rate of displacement of a group of sites in an area, the departure of sites from this mean is proportional to gravity anomaly.

The subsidence of the South Aegean basin since the Tertiary[12] coincides with an area of high positive isostatic anomaly[10], while the oceanic trench to the south of the Peloponnese is an area of negative anomaly, as is usual with trenches[13]. The South Aegean consists of subsiding continental material and so these findings are compatible with an association between high gravity anomaly and high rate of subsidence of continental material in this area. The recent sediments in the trench dip northwards (personal communication from W. B. F. Ryan) indicating a relative depression of the northern margin by approximately 1.0 m/millennium, comparable with the average rate of 0.87 m/millennium for the data discussed here.

Displacement of the coastline due to faulting would be expected to be erratic and of relatively high spatial frequency, while displacements resulting from small variations in isostatic anomaly would be of a broader nature with less local variation, due to the rigidity of the Earth's crust. This seems to be the case. The departures from the broad dome-like warping which are attributed to gravity in this study have a magnitude of 0.2–0.5 m/millennium and a spacing of the order of 50 km, while the variation attributed to faulting is of the order of 1.0 m/millennium over 25 km. This interpretation is tentative until there are more data on the seismicity of the area and on rates of displacement in other parts of the Aegean.

In view of the manifest tectonic differences between the Peloponnese and the average conditions in the western Mediterranean, the simplest explanation of the difference between the two curves in Fig. 2 is that the net eustatic change in the last 2,000 yr has been only of the order of 0.5 m, that the spread of data for the western Mediterranean is a result of local areas of vulcanism and seismicity, and that the spread of data for the Peloponnese is a result of a general depression of the margins of the Peloponnese, with areas of faulting in the Mani, and an uplifted ridge through Antikythera separating the trench to the south and the Aegean to the north, with a possible correlation between local variations in displacement and isostatic anomalies.

Extension of the Mid-Labrador Sea Ridge

EVIDENCE obtained during geophysical investigations aboard the USCGC Mariposa in the summer of 1967 strongly supports the hypothesis[1] that an inactive branch of the Mid-Oceanic Ridge lies buried beneath the axis of the Labrador Sea

Between 61° and 62° N the crest of the ridge is overlain by 1 km of sediment (Fig 1, profile 4, ref 1, profile *C–D*). To the south, where sediment accumulation rates are perhaps somewhat less rapid, the crest outcrops as isolated knolls on the sea floor North of 62° the ridge crest is covered by a thinner veneer of sediment (profiles 2–3) The Mariposa data apparently extend the known portion of the Mid-Labrador Sea Ridge to at least 64° The basement high strikes N N × W near the 55° W meridian as an apparent continuation from profile *C–D* (ref 1) The axis of the buried ridge lies slightly to the east of a line bisecting that part of the ocean basin which lies between the continental shelves In profile 3 the structural high has apparently acted as a partial dam for detritus Near 64° (profile 1) the basement rock has shoaled sufficiently to form Davis Strait and its rugged relief is replaced by a seemingly monolithic swell The absence of detectable sediment over this feature is probably attributable to current scour

The crest of the Mid-Oceanic Ridge is normally characterized by a unique magnetic signature consisting of a high amplitude anomaly and earthquake epicentres[2] Correlation of the postulated Mid-Labrador Sea Ridge with magnetic anomalies has been presented by Godby *et al*[3]. These investigators found two parallel zones with anomalously high magnetic signatures flanking a central swath of low anomalies and earthquake epicentres The crest of the prominent sub-bottom reflector which has been interpreted as basement (5 5 km/s layer of ref 1) correlates with the eastern magnetic anomaly zone The earthquake belt and the western magnetic zone, however, seem anomalous The frequency of earthquakes in the

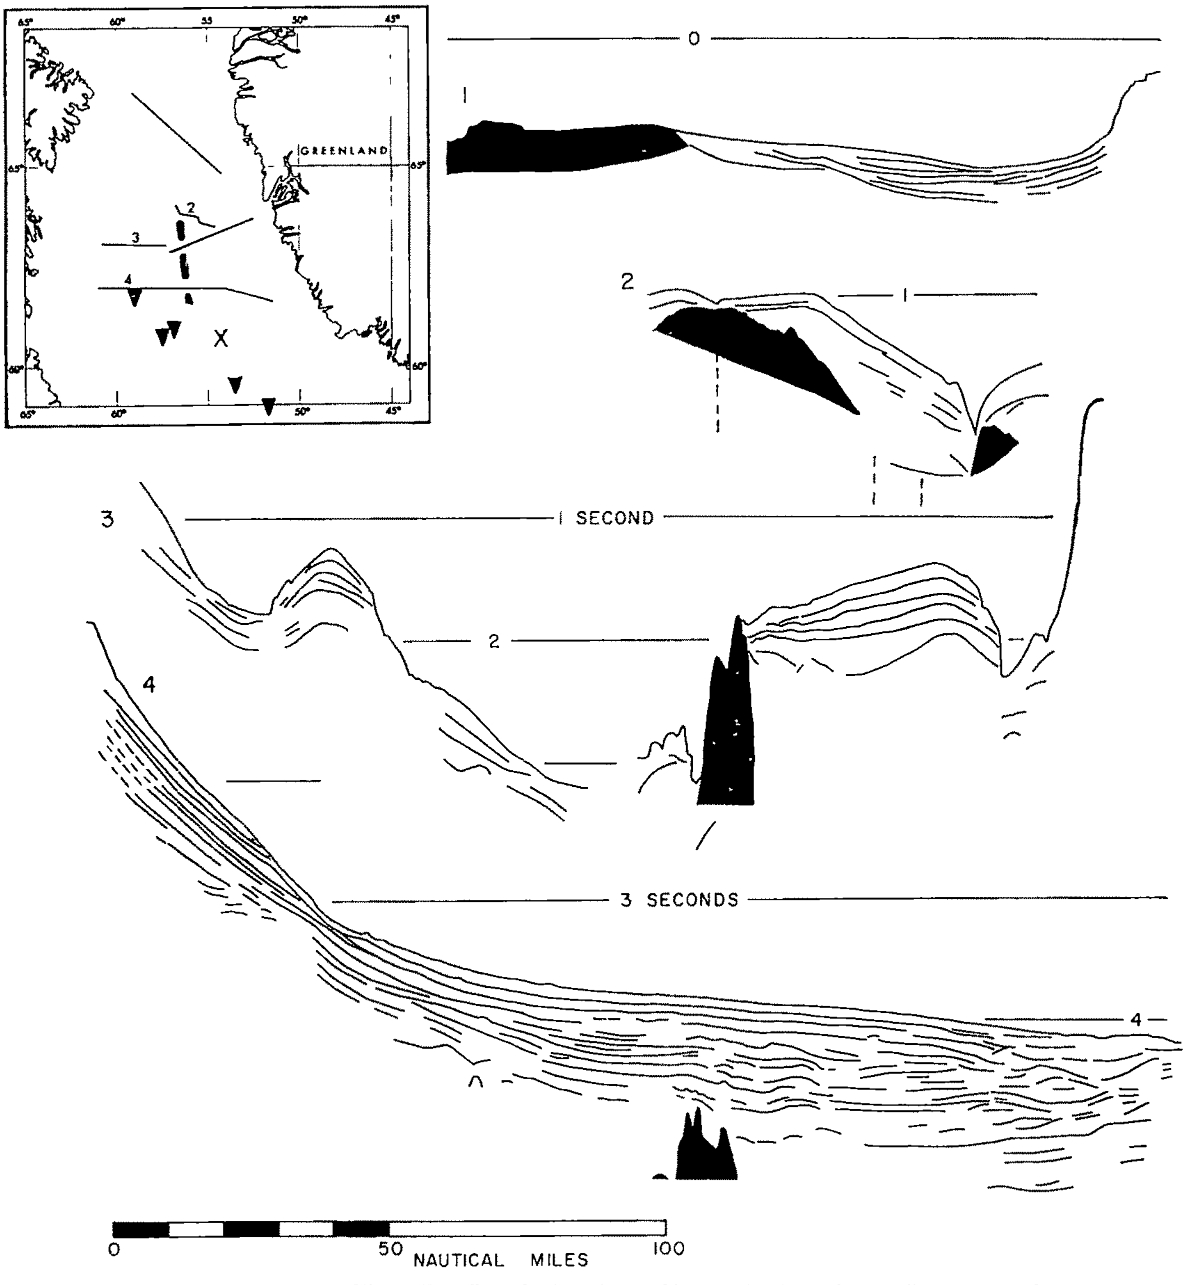

Fig 1 Four seismic reflexion traverses of the northern Labrador Sea Assumed basement is dark coloured Inverted triangles on index chart are earthquake epicentres, dotted lines indicate axes of high value magnetic anomalies[2], × marks axis of Drake *et al* profile of *C–D*[1] basement high, heavy dashed line indicates axis of basement high Travel time is two way—1 s is approximately equal to 1 km

northern Labrador Sea is about 10 per cent that of normal crestal regions of the Mid-Oceanic Ridge (personal communication from L Sykes) It seems plausible that these few earthquakes are associated with the graben structure of Cumberland Sound[4] The western magnetic anomaly belt which terminates abruptly near 60° N perhaps by a fracture zone or depth of burial[3] is anomalous and at the present is difficult to explain An unlikely possibility is that the prominent basement high may represent the eastern belt of rift mountains with the slightly seismically active centre swath, the ancient "rift valley" The western rift mountains would then be deeply buried beneath the continental rise The lack of an axial magnetic anomaly could be interpreted as a genesis during a reversed period of the Earth's polarity[5] This would, however, create an anomalously wide ridge–rift system within a narrow basin The more likely explanation that the basement high is the crestal region is favoured The relatively small amplitude (±400 gammas) of the axial magnetic anomaly suggests the origin of the feature during a reversed epoch, or perhaps the blanketing effect of sediments[6]

The seismic reflexion data do not indicate any support for a proposed submerged continental remnant in the Labrador Sea[4,7], however, the axial position of the crest would suggest the creation of Baffin Bay by ridge growth[6] with, as already suggested[8-10], the Nares Strait north of Greenland acting as a transform fault

Dementskaya and Dibner[11] suggested that a north-west–south-east geotectonic linear feature extends from Davis Strait through the Bay of Biscay Magnetic anomalies and topographic trends in the eastern Atlantic[12] may rather be a consequence of the north-west–south-east fracture pattern[13] The magnetics and buried relief of the Labrador Sea region (unpublished work of Johnson, Closuit and Pew) tend to support this hypothesis, however, we believe that the inactive ridge branch originated just to the west of the crestal region of the Mid-Atlantic Ridge near 53° A former axis of the Mid-Oceanic Ridge, now subsided, and in a north-west–south-east trend diagonally across the North Atlantic, not unlike Darwin Rise in the Pacific[14], is a possibility warranting further investigation Rates of subsidence for the Mid-Oceanic Ridge have recently been presented[15] and appear adequate to have suppressed this feature, assuming an early Tertiary or Mesozoic age

We thank the officers and crew of the USCGC Mariposa and Al Closuit, John Jacobsen, Jim Kosales and Burt Tanner for their co-operation This work was supported by the US Naval Oceanographic Office and the Geophysical and Polar Research Center of the University of Wisconsin under an Arctic Institute of North America grant

Has the Pacific Basin moved as a Rigid Plate since the Cretaceous ?

McKenzie and Parker[1] have shown from displacements along faults and from seismic first motions that the North Pacific seems to be moving as a rigid plate relative to the surrounding continents This motion is uniquely defined by a rotation axis which they estimated to be located near 50° N , 85° W at the southern end of Hudson Bay The sense is towards the north-west, clockwise as viewed from the pole Palaeomagnetic evidence from North America and the magnetization of Pacific Ocean seamounts suggest that this rotation dates from Cretaceous time (10^8 yr), and that the total angle is perhaps as great as 100°, an average rate of 1° per million years

Grommé, Merrill and Verhoogen[2] critically examined the palaeomagnetic data for the Cretaceous of North America, presenting the results in the conventional manner as virtual geomagnetic poles (a VGP is the pole of that unique axial dipole field which gives the observed magnetization at a given site) Six out of the nine poles that they consider reliable are tightly grouped about a mean position 67° N , 172° W These poles have all been radiometrically dated and the ages range from 84 to 138×10^6 yr So, within the present accuracy of the palaeomagnetic measurements, the North American continent remained fixed relative to the assumed geomagnetic pole for most of the Cretaceous, 50×10^6 yr

Richards, Vacquier and Van Voorhis[3] recently summarized the results on the magnetization of Pacific Ocean seamounts as determined by the method of Vacquier[4] They assume that the total magnetic field anomaly associated with a seamount is primarily a consequence of a uniform magnetization throughout its volume, and with this simple assumption they estimate the direction and intensity of magnetization They can explain about half of the anomaly in this way and "best" fits require that the magnetization induced in the present geomagnetic field is a small fraction of the total magnetization The average virtual geomagnetic poles for six seamounts in the Hawaii development area and four seamounts near Japan are 21° E , 58° N ($\alpha_{95} = 12°$, $k = 19$) and 14° W , 51° N ($\alpha_{95} = 7°$, $k = 10$), respectively Richards *et al* [3] discussed K–Ar age determinations made by others on dredge samples from the two groups of seamounts they are probably mid-Cretaceous (80×10^6 yr)

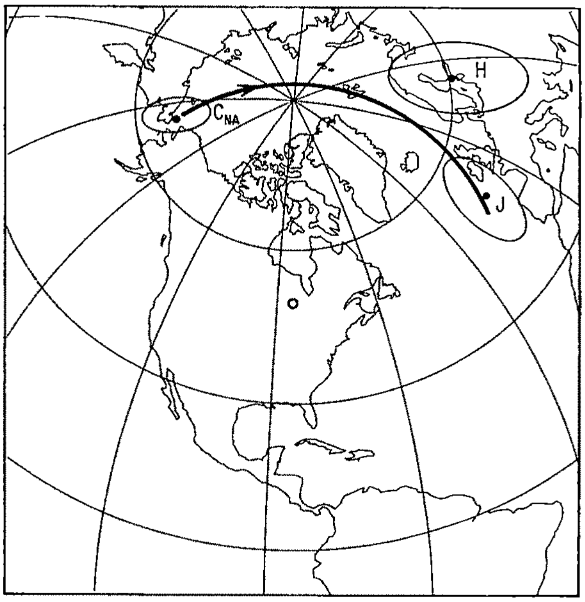

Fig 1 Cretaceous virtual geomagnetic poles for North America, C_{NA}, Hawaiian seamounts, H, and Japanese seamounts, J An equal area projection about the axis of relative rotation determined from seismic first motions

If the Pacific Basin has rotated about the McKenzie-Parker axis since the Cretaceous and if the seamount virtual geomagnetic poles were once coincident with the Cretaceous poles of North America, then the motion would carry the seamount poles along a small circle about the axis of relative rotation The present position along the small circle of the seamount poles, relative to the continental pole, would indicate the total angle by which the Pacific has rotated The geometry is depicted in Fig 1, an equal area projection about the axis of relative rotation, showing the North American Cretaceous, C_{NA}, and oceanic, H, J, virtual geomagnetic poles The angles between the North American pole and the two mean seamount poles, one near Ireland, the other in the Gulf of Finland, are 70° and 90°, respectively, indicating an average rotation rate of the Pacific Basin of 1°/million years

Admittedly, the Hawaiian result alone is not convincing and there is a huge scatter in numerous unpublished seamount poles (personal communication from M Richards) But these preliminary data are certainly consistent with the hypothesis of large scale rotation of the Pacific relative to North America The rotation axis used here comes from the analysis of only ten years of seismic data and is uncertain to perhaps ten degrees Even so, Fig 1 suggests that the Pacific Basin has moved as a rigid plate about an axis, fixed relative to North America, not too different from the McKenzie–Parker axis and that this rotation began at least in the mid-Cretaceous It may be older

A more detailed study of the palaeomagnetic evidence, the tectonic implications and suggestions for corroborative experiments, is in preparation From preliminary results it seems possible that the rotation dates from Lower Cretaceous time (140×10^6 yr) and that the Pacific Basin has been a rigid plate moving about an axis constant in time and fixed with respect to the surrounding continents

Nature of Glaciated Landforms

GLACIAL erosion has been accepted for more than a hundred years, yet there are many loose assumptions about the real nature of glaciated landforms This lack of knowledge makes it difficult to explain the erosion processes concerned If more precise information were available, these processes and landforms could be applied to test several theories in ice physics

Descriptions of glaciated landforms are surprisingly vague Much has been made of the textbook U-shaped valley or the schrundline corrie, but there is little information to suggest how typical these landforms really are More needs to be known about their exact form, the frequency of different types and about their relationships to the surrounding relief, geological structures and to the processes which have shaped them

Any study has to be exploratory, and for this reason the corrie (or cirque) seems a very suitable choice of landform Using this helps to minimize the difficulty that most of the glaciated areas of northern Europe were covered during the Ice Age by a complex sequence of several different types of ice cover Corries have also obviously been submerged by ice sheets for long periods, but it seems from their distinctiveness as landforms that most of them have been relatively little affected by this phase in their history This is really what would be expected, for observations on the Antarctic ice sheet today[1] show that it is relatively slowly moving and presumably fairly protective in its effects away from the principal lines of ice flow

Corries are mostly on mountain flanks and are bypassed by the chief avenues of ice discharge They have been found to possess a great overall similarity from area to area, but where on other grounds there is reason to suppose that they have been overrun by more strongly flowing ice than normal, they have slightly different characteristics or else are rendered almost unrecognizable by dissection In addition, really good examples of corries tend to be absent from densely dissected areas and presumably, therefore, from areas of rapid ice streaming—such as various south-westerly parts of the Scottish Highlands

Second, corries are suitable for a preliminary study of glaciated landforms because a much better estimate of the thickness of the ice assumed to be responsible for the hollow can be made than for a valley glacier or for the ice covering a roche moutonnée Finally, after the well integrated work of Lewis[2] and his associates on Veslskautbreen—a small corrie glacier in Norway—we know much more about the characteristics and detailed three-dimensional flow pattern of corrie glaciers than of any other glacial type

The most suitable way of tackling the problem of the origin of a variable natural occurrence such as a corrie is to analyse various aspects of the shape of large numbers of examples A sample containing more than one hundred well formed chiefly Scottish corries as well as, for comparison, other similar mountain hollows of much more disputed origin was taken and their similarities and differences were analysed Various aspects of corrie shape were measured, one of the most important being the longitudinal profile The shape of this is obviously very pertinent to the question of corrie formation, because it is a profile in the direction of ice movement The most satisfactory way to define similarity of longitudinal profiles between different corries was thought to be to find a best-fit curve with as simple a formula as possible, to fit as much of the sample as possible Various types of curve were tried, and the most suitable was found to be a logarithmic curve of the type $y=(1-x)e^{-x}$ A term k was also introduced into the equation $[y=k(1-x)e^{-x}]$ to allow for the fact that corrie steepness varies, while still retaining the same type of curve for all examples

This curve has many advantages (1) It can be fitted to 81 per cent of the corries An arc of a circle has previously been used to characterize the bed of a corrie glacier (for example, by McCall[3]), but this was found to be inappropriate in the present study—it bore no resemblance to almost half of the corrie profiles

(2) The k curve could also be used to distinguish corries from non-corries, few of which it fitted well In contrast, no distinction could be made between the two groups of mountain hollows by using an arc of a circle With the latter the proportion of hollows fitting was precisely the same for both groups (53 per cent fit)

(3) The formula of the k-curve is simple and it is an easy curve to fit Obviously more complex curves could have been found to fit each individual corrie exactly, but this would defeat one of the chief purposes of this method of landform analysis

(4) The value of the term k can be used to define several types within the corrie group of landforms itself It can also be used as a single parameter to plot against the various independent variables which may influence corrie shape—rock type, aspect, climatic factors, environmental relief, the stage reached in erosion and so on

This is an obvious advantage over the arc of a circle. With the latter, in order to describe a corrie accurately it is necessary to know the radius of curvature, the gradient of the hollow and the angle subtended at the centre of the circle by the length of the corrie profile The *k*-number on the other hand, within one term, describes both the shape and steepness of the corrie

Corries may look very different, but it seems that many of these apparent differences are partially caused by the surrounding relief and are not reflected in the longitudinal profiles of the corries themselves Relevant features are the difference between a peak towering above a corrie, as there is in the case of Glaslyn on Snowdon, or a surrounding plateau as in the Cairngorms Despite the different superficial appearances of different corries their profiles are astonishingly similar—81 per cent of those studied fitted the curves very closely Most of the remaining 19 per cent were more angular caricatures of the rest, caused by specialized lithological situations In fact, the corrie profiles which have been studied can be arranged in a more or less continuous series, with the bulk of the corries—those fitted by the *k*-curves—in the middle At one end of the series they gradually become more angular until the classic schrundline corrie is reached Oddly enough, at the other end of the series is the exaggerated L-shaped corrie, which has also attracted attention in the past It is perhaps symptomatic of the contrast between classical geomorphology and the present day more multivariate and quantitative approach that the two corrie types which had previously been regarded as typical textbook forms are, in fact, quite rare and are exaggerated caricatures of the bulk of the forms

The similarity which has been discovered between corries in very different situations must be the result of common factors The most obvious one is the influence of glacial erosion processes, in particular the characteristic "rotational" flow pattern of the corrie glacier

With the similarities defined it is possible to pinpoint and analyse the differences between the hollows These differences are of three types (1) Large divergences from the *k*-curves, which define mountain hollows not caused by corrie glacier erosion (2) Smaller random divergences caused by occurrences like ice sheet overflow, lithological changes and so on (3) Systematic variations which give rise to the different values of *k* Corries with different values of *k* are found all over Highland Britain, and many areas contain all types, which suggests that the controlling factors are very local —principally structural rather than climatic The schrundline corrie, for example, is especially associated with granitic rocks on account of particular jointing characteristics often found in these

One general conclusion which can be drawn from the whole study can be mentioned It is quite clear that both erosion processes (related to the glacial flow pattern) and rock structure are very important in the production of glaciated landforms They act together and neither can really be said to dominate the other

The research described here was carried out while I held a DSIR research studentship in the Department of Geography, University of Cambridge, from 1963–66 I thank all those who gave their support

Petrogenetic Significance of Alkali Feldspar Megacrysts and their Inclusions in Cornubian Granites

THE problems peculiar to the Land's End granites are, by virtue of their chemical mineralogical and geophysical affinities[1], common to other exposed granites in Cornubia Findings concerning the Land's End granites can therefore be extended to all granites in south-west England and possibly to similar granites throughout the world

The porphyritic biotite granites contain large alkali feldspar crystals of variable length (up to 18 cm) These big crystals (megacrysts) form a coarse microperthite with albite and may contain small crystals of all the other minerals comprising the granite The most common inclusion is biotite which may be centrally or zonally arranged or irregularly distributed

This preliminary communication describes the nature of the zonal distribution of minerals within the megacrysts and discusses their petrogenetic significance

Alkali feldspar megacrysts are primarily a feature of the coarse porphyritic granites of Cornubia At Land's End they are an average of 6 cm long and constitute about a quarter of the total rock volume (excluding groundmass perthite) The megacrysts are white when fresh and tabular in habit, they are flattened parallel to (010) and generally elongated about a line bisecting the acute angle between the *a* and *c* crystallographic axes Twinning is usually on the Carlsbad law and the composition plane (010) may be stepped or curved The crystals are set in a coarsely granular groundmass of anidiomorphic quartz and perthite, plagioclase (albite–oligoclase), biotite, subsidiary muscovite and frequent tourmaline The margins of the megacrysts often show implicate texture, especially where the crystals are proximal to quartz, although straight contacts are not unusual Contacts with plagioclase, which is invariably replaced, are serrate or lobate, while mica/megacryst contacts are straight or zigzag depending on the orientation of the mica Secondary muscovite frequently penetrates the megacrysts along cleavage cracks or follows the direction of perthite strings, primary nucleation would be expected at sites where the anorthite molecule was breaking down

In hand specimens both biotite and quartz are obvious inclusions; the biotite is often arranged in well defined zones which are frequently parallel to the boundary of the megacryst The number of zones varies, with at least one principal inner zone and occasionally one or more peripheral zones 1–2 mm from the margin Quartz inclusions are similarly arranged in peripheral zones as

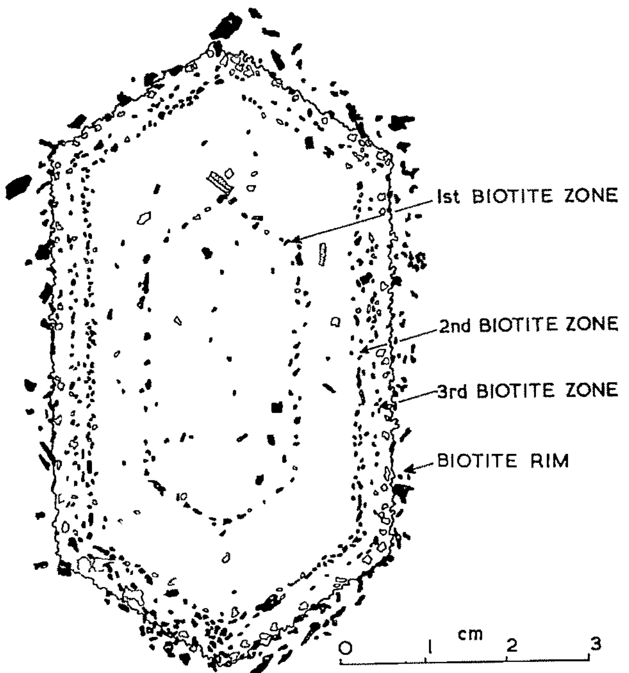

Fig 1 Perthite megacryst showing zones of inclusions Black, biotite, clear, quartz, stippled, plagioclase (Specimen from Carn-a-langa quarry, Land's End)

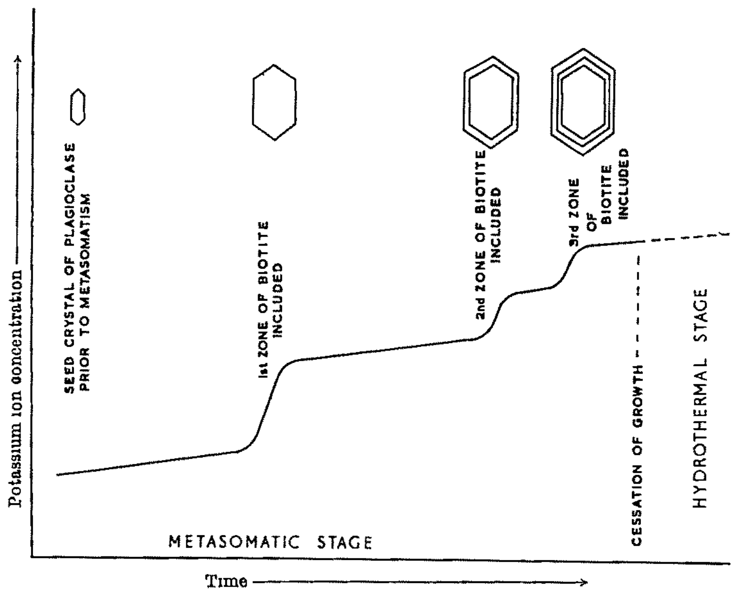

Fig 2 Time versus concentration of potassium ions, illustrating the stages at which the three inner biotite zones of Fig 1 feldspar become included

discrete, elongated, clear patches Plagioclase occurs as small (0 6 mm) subhedral to euhedral crystal inclusions which vary considerably in shape and size and, although the centres are often preferentially altered to secondary micas or clay minerals (a reflexion of the breakdown of the more calcic core), the crystals are frequently mantled with a thin pellicle of clear albite Tourmaline inclusions usually show a replacement texture towards the feldspar and are therefore secondary in origin[1]

In thin section the inclusions reveal significant features The quartz grains which occur as rounded water-clear blebs, 0 3–1 mm long, rarely exhibit strain effects, while the metasomatic quartz "pools" or composite masses in the groundmass frequently show strain shadows and indicate late stage replacement textures; likewise, the interfeldspathic biotites are not, as a rule, as large (< 2 mm) or as chloritized as the intrafeldspathic varieties These two facts suggest that the included biotite and quartz are derived from the initial fine grained crystal "mush" early in the pluton's history This pre-dated the extensive metasomatic and contamination effects which were superimposed on this aplogranitic material[1,2] as crystallization proceeded, and the important silico-potassic aqueous phase separated from the "magma", inclusions suggest a grain size of 0 3–2 mm for the aplogranite

Fig 1 illustrates a typical megacryst with several zones of included biotite and quartz, these zones of oikocrysts within the chadocryst can be expressed in diagrammatic—graphic form (Fig 2), which illustrates the relationship between time and the concentration of potassium ions in the perthite megacrysts The correlation between the biotite zones, megacryst growth and accelerated periods of potassium metasomatism is evident, and it can often be shown that the obtuse angles in the biotite zones lie on common axes These represent uniform directions of growth, and by tracing the axes back to their origin some estimate of the original size of the seed crystal can be obtained The distribution and orientation of these seed crystals within the peripheral zones of the pluton, and their subsequent metasomatic history, can be shown to have some bearing on the distribution of the coarse porphyritic and non-porphyritic granites of south-west England[1]

The granites of the Cornubian peninsula are composite, serokinematic to postkinematic rocks representing the upper protrusions of a high-level pluton elongated from W S W to E N E , the possibility that the granite outcrops of Devon and Cornwall could belong to the same mass was realized by de la Beche in 1839 and referred to in his classic report[3] Furthermore, it has been shown that the Land's End granite is a composite body consisting of a coarse grained porphyritic outer phase, and a medium to fine grained (non-porphyritic) core[1], in several localities this core has extensively veined or broken through the porphyritic envelope

Fig 3 is a cross-section of the Cornubian pluton In it a correlation is made between the granites of the Scillies, Land's End, Carnmenellis, St Austell, Bodmin and Dartmoor, and illustrates the composite nature of the pluton. In the west, very little non-porphyritic granite is exposed, this being overlain by the coarse porphyritic envelope, in the east, the non-porphyritic granite is often the rule, with isolated outcrops of the coarse porphyritic envelope exposed on hills and tors (for example, Hay Tor, Dartmoor), and nearer the margin These facts indicate a lower level of erosion in the Dartmoor granite and the sloping nature of the roof zone from east to west This is confirmed by geophysical evidence which shows that the pluton and its roof become thinner from east to west[4]

Although field evidence at Land's End suggests partial remobilization of the finer core[1], the composite nature of the granites is not attributed to separate intrusions, but rather to the concentration of the metasomatizing agent, potassium, beneath the granite roof or within a differentiation "front". The potassium ions are believed to have been concentrated around the cooling margin of the granite by migration along a thermal and/or chemical gradient[1,5] The action of potassium metasomatism outside the main body of the granite is demonstrated by the

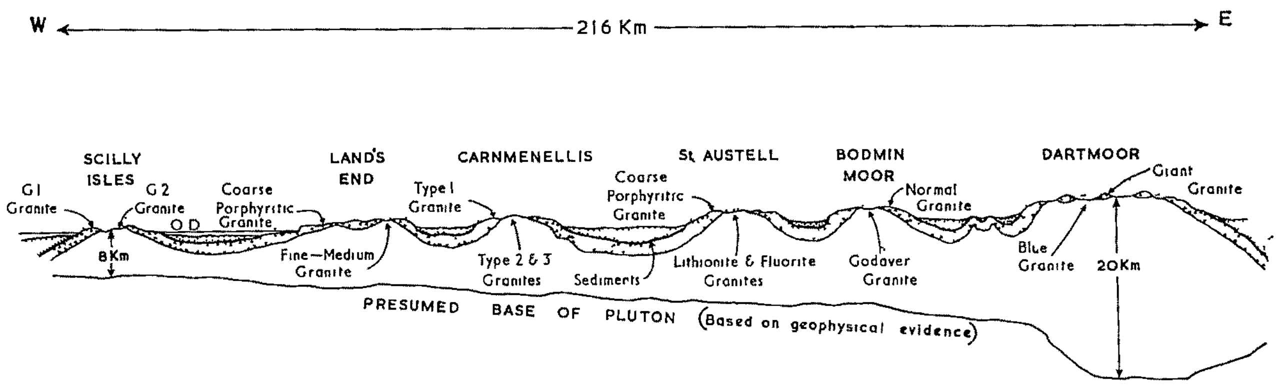

Fig 3 Correlation diagram of Cornubian granites Fine stipple, country rock, coarse stipple, coarse porphyritic granite envelope, white, medium to fine grained granite (texture of the granite below 2,000 ft is unknown) (Thickness of pluton based on geophysical evidence[6])

development of biotite-rich hornfelses formed by the biotization of hornblende–plagioclase hornfelses[5,6]. The effect of late-stage potassium metasomatism within the granite (autometasomatism) is illustrated by the development of double-enclaves, and the metasomatic replacement of early formed plagioclases which then continued to grow across granite/hornfels and granite/aplite contacts. The development of these secondary alkali feldspar megacrysts across aplite/pegmatite and aplite/granite contacts in the Carnmenellis granite has previously been cited as evidence for the postconsolidation development of these crystals[7].

Field evidence permits the interpretation that the alkali feldspars grew under the influence of potassium metasomatism within a crystal "mush" or near solid environment. It is, however, the primary origin of these feldspars which is being questioned, and I conclude that the cores of many of the alkali feldspar megacrysts were originally magmatic in origin and albitic (An 0–An 10) in composition; a quartz–orthoclase–plagioclase–biotite matrix would be a natural presumption for anatectic granites[8,9]. The crystals were orientated into parallel alignment and occasional convection swirls by viscous flow; this took place during the progressive emplacement of the crystal mush while under the influence of a regional stress-gradient field. During periods of ensuing potassium metasomatism, replacement of these "seed crystals" was accompanied by irregular endoblastic growth, the groundmass minerals immediately adjacent to the seed crystals probably constituted an "aplitic" matrix of quartz, plagioclase and biotite, lubricated by a hydrous phase[2], and were enveloped during the increased rate of growth of the seed crystal which later slowed down because of impoverishment of suitable adjacent material. During periods of slow growth, it seems that the surrounding minerals were pushed aside, only to become enveloped when crystal growth accelerated in some way. These zones or periods of accelerated growth are correlated with advancing waves of potassium metasomatism, or increases in potassium concentration within the granite which, by virtue of an established concentration and temperature gradient, tended to migrate towards the periphery and give rise to a highly metasomatized marginal granite. Alternations of highly porphyritic granite within the coarse non-porphyritic granite are attributed to metasomatic fronts the activity of which was curtailed by the attenuation of the metasomatic physicochemical conditions.

Mesospheric–Stratospheric Coupling

THIS communication describes an investigation of mesospheric–stratospheric relationships between electron densities and collision frequencies with stratospheric temperature or constant pressure heights as measured during winter periods of 1964 and 1965 by the wave interaction method of Ferraro and Lee[1].

Shapley and Beynon[2] indicated evidence for the correlation of the phenomenon known as stratospheric warmings with the winter anomaly in ionospheric radiowave absorption. They showed that periods of an extraordinarily warm stratosphere coincide with periods of strong radiowave absorption. Beynon and Jones[3] believe there is a common cause behind the similarities in behaviour of the seasonal variations of monthly means of stratospheric temperature and mesospheric neutral density and collision frequency. Regression equations developed by Quiroz and Thompson[4] show correlations between neutral density, pressure and temperature in the stratosphere and mesosphere to be good in general. We have investigated associations of electrical effects and neutral temperature and of mesospheric–stratospheric coupling.

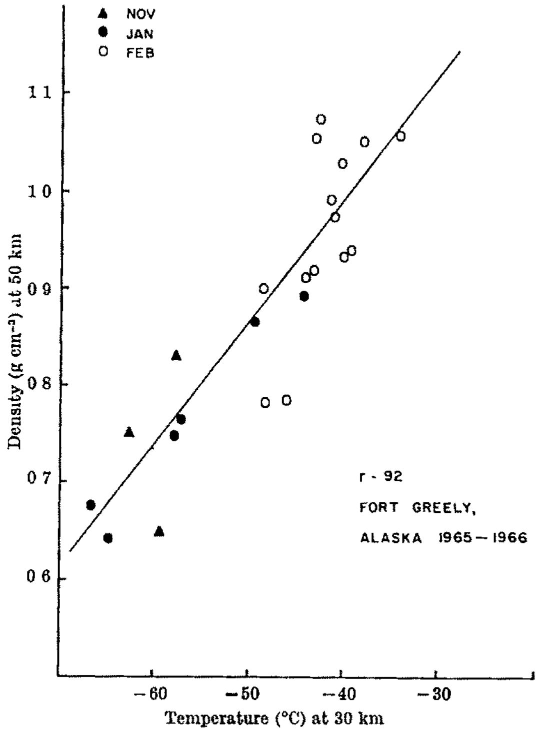

Fig. 1. Fort Greely temperature and density.

In the *D* region, where the electron density generally increases with height, an increase in neutral temperature in and below a layer will cause the layer to lift. Thus the electron density at a fixed height in the layer decreases. Solar influences may, however, interfere with this relationship. An increase in solar activity may increase the electron density in a layer, whereas an increase in zenith angle tends to raise the layer.

Mawdsley[5] suggests that enhanced electron density is related to winter high-latitude anomalies of temperature through a photochemical process involving nitric oxide. Motions responsible for high densities and temperatures in the mesosphere might also be responsible for temporary enhancements of nitric oxide content of the mesosphere, leading to greater electron production by Lyman alpha radiation. J. B. Gregory (private communication) feels that "... the basic mechanism (for such correlations) is the upward development of long planetary waves of the troposphere and stratosphere".

Electron collision frequency is a function of electron temperature and neutral density. Electron temperature in the mesosphere is influenced by solar radiation, heat conduction—particularly from the thermosphere—and heat convection. Convection which would increase neutral density and electron temperature would also increase collision frequency.

Absorption of radiowaves is caused by a loss of energy through electron-neutral collisions, the absorption co-

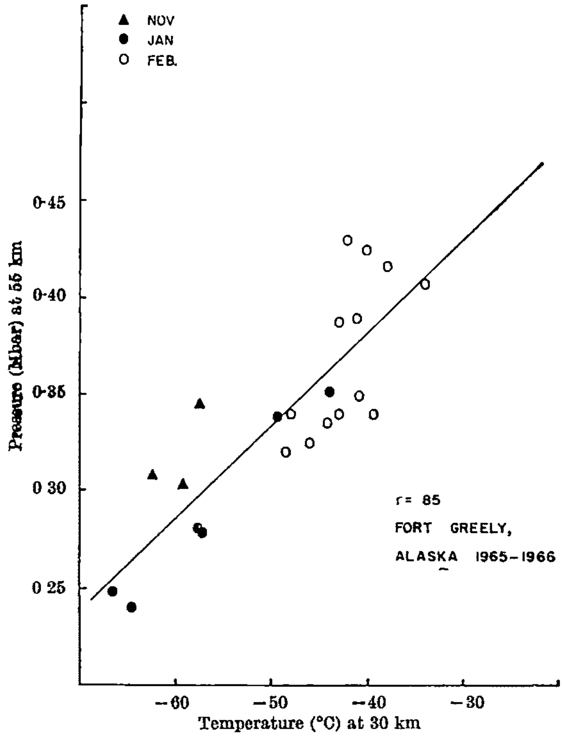

Fig 2. Fort Greely pressure and temperature

efficient is proportional to local electron collision frequency and electron density, and an increase of either or both of these variables might cause the kind of associations reported before[2,3]. The absorbing layer may be raised without change in absorption if, for example, an increase in temperature at lower layers causes an increase in neutral density and collision frequency and a decrease in electron density.

If planetary waves are solely responsible for electrical-neutral coupling, then there should be some associated time lag. This was not evident in Shapley's investigation although it may account for lack of coupling when "quiet" winters are studied.

Combination of the gas law and the hydrostatic approximation gives

$$\mathrm{Ln}(p)-\mathrm{Ln}(p_0)=-\int_{Z_0}^{Z}\frac{g}{R_0T}\,\mathrm{d}Z$$

This equation shows that through hydrostatic coupling, an increase in temperature in a column of air between Z and Z_0 would cause an increase in pressure at the height Z if the pressure at Z_0 did not vary appreciably. At sufficiently high levels, the pressure increase is of such magnitude as to cause a density increase in spite of the temperature increase. This mechanism accounts qualitatively for the results of Quiroz and Thompson.

Perturbations moving vertically in the wind fields may cause similar disturbances at different levels. This could result in the type of linking suggested by Mawdsley. Apparent linking of parameters at different levels may only be the result of similar reactions of the various parameters to outside influences. For example, an increase in solar activity might cause an increase in neutral and electron temperature in the mesosphere and in temperature in the stratospheric ozone layer.

The Meteorological Rocket Net (MRN) data reports at Fort Greely (Alaska), Fort Churchill (Canada) and Cape Kennedy (Florida) were chosen because of their larger number of rocket shots reaching 55 km. These reports were used for comparing stratospheric temperature with density and pressure at 50 and 55 km. *NASA Technical Reports* *R*-211 and *R*-245 were chosen as sources of data for comparison of atmospheric density at 70 km with stratospheric temperature for Wallops Island.

Table 1. SUMMARY OF TEMPERATURE AND DENSITY COUPLING

Site	Correlation coefficient
Fort Greely, Alaska 1965–66	R = 0·92 at 50 km Nov., Jan., and Feb. data
Cape Kennedy, Florida 1965–66	R = 0·58 at 50 km Nov., Jan., and Feb. data
Wallops Island, Virginia 1961–63	R = 0·59 at 70 km Nov., Dec., Jan., Feb., and March data

Fig. 1 shows temperature and density coupling at a northern location, and Table 1 summarizes the results at other locations.

The greater correlation coefficient and more evident seasonal trend of monthly data at Fort Greely indicate the greater degree of covariant changes associated with high latitude wintertime stations. The Wallops Island result indicates that the coupling shown here and previously by Quiroz and Thompson does extend well into the mesosphere. Fig. 2 shows the existence of coupling of pressure at 55 km with stratospheric temperature.

In order to determine "small scale" coupling, changes of temperature and density over 1 to 5 days at different levels were compared. Because observations were not available on consecutive days, changes over the shortest period that the frequency of the soundings permitted were used. Fig. 3 indicates that small scale coupling does exist, although it is not of the magnitude of the larger scale seasonal coupling. Notice that seasonal trends are now absent along the line of regression.

Because of the scarcity of wind data at 40 and 50 km levels, only a small portion of the data was spaced closely enough for a study of vertical coupling.

Fig. 4 shows time series graphs for Fort Greely and White Sands, selected for the years 1962–63 because of the significant change in zonal winds during the "sudden warming" which occurred on January 18, 1963, at Fort Greely. There is no significant coupling, except for some large scale events, such as the slow trend reversing the easterly wind to a westerly wind after the "sudden

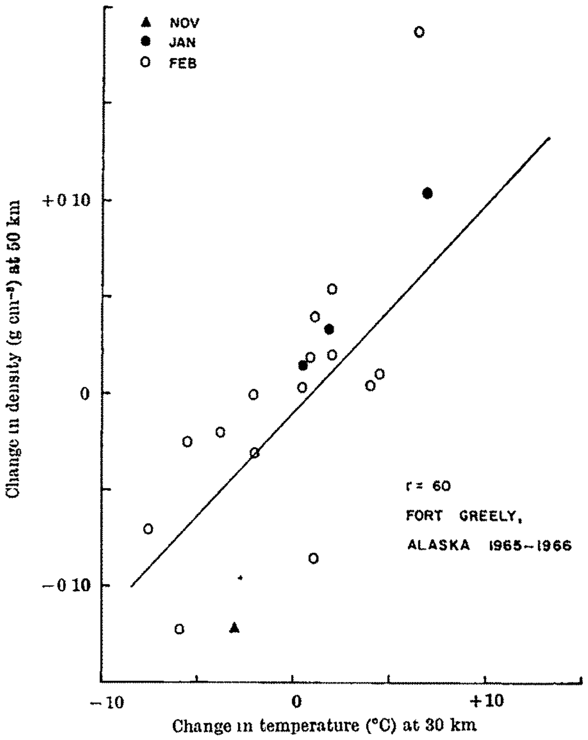

Fig 3. Fort Greely change in density at 50 km and change in temperature

warming" It is difficult to detect coupling of smaller perturbations because of missing data

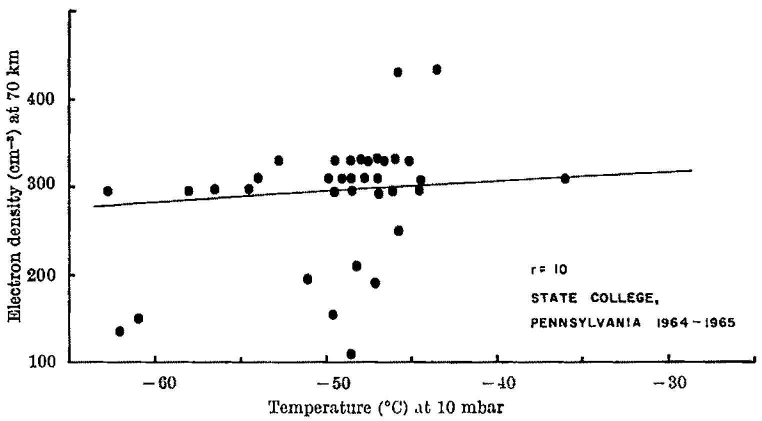

Fig 5 Electron density and temperature at State College, Pennsylvania

Electron density and collision frequency measurements have been provided on a semi-daily basis by phase and amplitude wave interaction experiments conducted by the Ionosphere Research Laboratory at the Pennsylvania State University by Ferraro and Lee The electron collision frequency used is representative of electron-neutral collisions Because the measurements were made in the mesosphere over State College, the heights of upper air constant pressure levels and temperature at 10 mbar at the nearest station, Pittsburgh, Pennsylvania, were chosen for comparison Radiosonde balloon ascents are made here twice daily with special care in order to reach high elevations The measurements at 0700 h and 1900 h were averaged to give a representative 10 mbar height or temperature

Measurements of electron collision frequency were available for 16 days in January and 16 days in February 1964 The measurements were made for heights of 70, 75, 80 and 85 km several times daily, usually from 1000 h to 1500 h EST, and then averaged to give a daily average collision frequency Electron density measurements at 70 km for 39 days in January, February, March and December of 1964 and January 1965 were also available for comparison In this case, an approximate value was chosen for 1200 h EST to be compared against 10 mbar temperature in Fig 5

The coupling between temperature at 30 km and atmospheric pressure and density at higher levels as detected by Quiroz and Thompson has been confirmed and found to extend to higher levels then previously noted The coupling seems to be stronger for high than for low latitudes Correlations are largely the result of covariant seasonal changes, and only partly the result of short period changes This indicates that the coupling of these parameters is strongest in periods of large temperature variations at high latitudes in the winter hemisphere

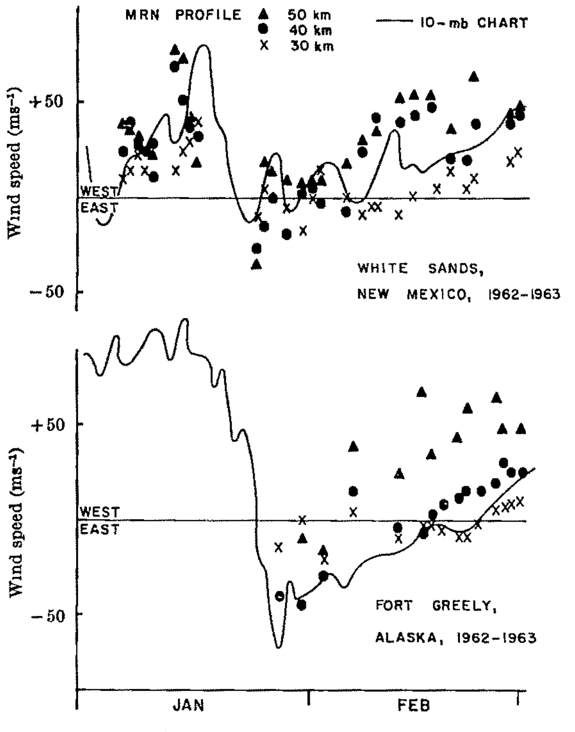

Fig 4 Westerly winds at 10 mbar and at 30, 40 and 50 km

Correlations between 70 and 35 km were smaller, possibly partly because of increased error of measurements and the smaller number of measurements made at these levels In general, some hydrostatic-type coupling exists between middle stratosphere temperature and pressure and neutral density of the upper stratosphere and lower mesosphere The existence of short-period dynamic wind coupling is not evident from the results, but zonal winds of different levels do seem to undergo similar major long-period changes during the winter months

Because of the large variability of temperature, neutral density, electron collision frequency and electron density during the winter months, it was hoped that a coupling of these parameters could be discovered No significant relation was, however, found between temperature in the stratosphere and electron density or collision frequency Significant relationships between these may not exist, or may be obscured by time lags, observational errors or by the influence of other variables Because previous "successful" comparisons were made during periods of "explosive warmings", it is still possible that there is no significant coupling between electric variables in the mesosphere and middle stratosphere temperatures during ordinary warmings.

PHYSICS

Effects of Drag-reducing Additives on Vortex Stretching

Giles and Pettit[1] have shown that, in tubes of small diameters, solutions of additives which reduce turbulent drag can apparently maintain laminar flow at Reynolds numbers greatly above the limit of about 2,000, which for water usually marks the onset of turbulent flow The friction factor rises above the Hagen–Poiseuille line, however, and Giles and Pettit attribute this to a shear-thickening of the fluid, and suggest that the viscosity of the additive solution effectively increases at sufficiently high shear rates.

This explanation seems improbable because results for two different tube sizes, one nearly twice the diameter of the other, correlate on the basis of Reynolds number. If shear thickening were involved, the apparent viscosity would be expected to be a function of shear stress, which must be greater in a smaller diameter tube than in a larger one for equal Reynolds numbers. Thus the results should not correlate with Reynolds number. An alternative explanation could be that although dye traces at the centre of the tube indicate that the flow there is laminar, nevertheless non-linear laminar oscillations occur close to the walls of the tube. As Stuart has shown[2], this could give rise to an increased friction factor. (Although Stuart's work refers to plane Poiseuille flow, the probability that similar finite-amplitude disturbances can occur in Poiseuille flow through a pipe has been demonstrated by Dixon and Hellums[3].) If the disturbance flows were geometrically similar for the same Reynolds numbers in different tubes, the friction factor would then be a function of Reynolds number.

Evidence that the flow with additives is not completely steady in quasilaminar conditions was obtained as follows. Dye was injected into the flow through a glass tube (Fig. 1) so that the dye would flow close to the walls of the tube. There were two dye injection holes at 90° spacing. At the top of the tube was a rounded entry slightly smaller in diameter than the bore of the tube: the resulting step should tend to provoke early transition. The speed could be varied by varying the height of the outflow point. Fig. 2*a* shows the dye flow with 92 p.p.m. polyethylene oxide 'Polyox *WSR* 301' at a Reynolds number, based on diameter, of about 4,000. (In Fig. 2*a*, as in Figs. 2*b* and 2*c*, the flow is from top to bottom and the exposure time is about 30 μs.) Although the dye filament does not break up into turbulence it is nevertheless disturbed. Such disturbances could have caused the manometer oscillations reported in ref. 4. For comparison, Figs. 2*b* and 2*c* show dye traces for plain water and for 11 p.p.m. of 'Polyox', respectively, at a Reynolds number of about 8,000. The latter very dilute 'Polyox' flow, although apparently turbulent, shows much less complete mixing of the dye than the water flow.

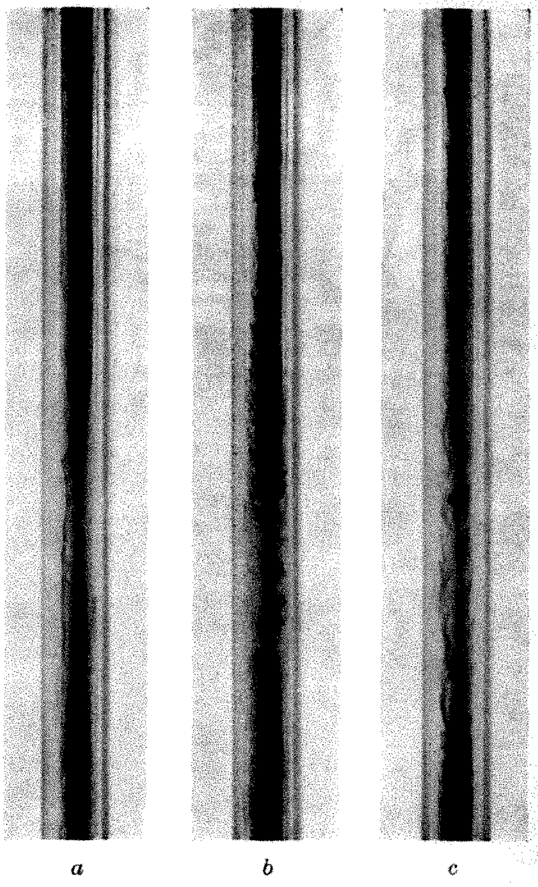

Fig. 2. Dye filament photographs.

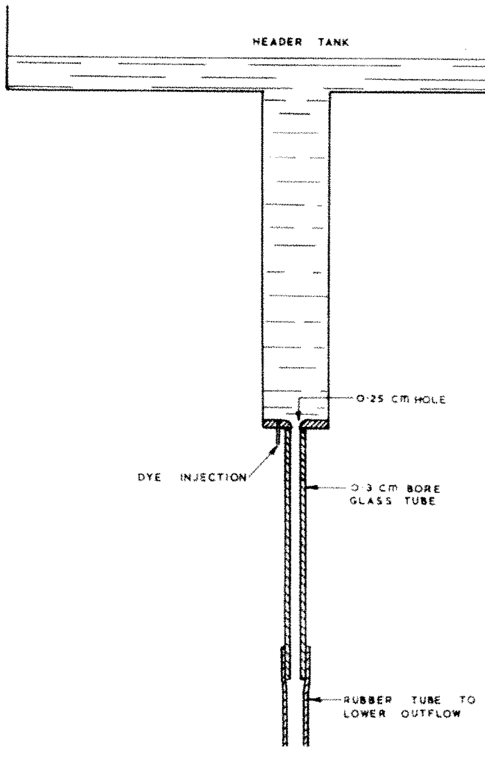

Fig. 1. Flow visualization apparatus.

Pfenninger gave a possible explanation of such effects[5]—additives can inhibit vortex stretching. This could delay the breakdown of non-linear laminar oscillations into turbulence, because the oscillations can be regarded as a pattern of vortex filaments close to the pipe wall, chiefly transverse to the flow direction, and breakdown into turbulence involves a convolution and hence a stretching of these vortex filaments. Similarly less mixing would occur in fully turbulent flows if vortex stretching were reduced. Some support for this hypothesis was provided by the experimental arrangement sketched in Fig. 3. The rod shown was rotated at about 5,000 r.p.m., so generating a thin core of vorticity on the axis of the tube leading to the orifice. As the flow passed through this, the vortex filament was stretched and intensified as in a bath-plug vortex. In Fig. 4 the time for a given quantity of fluid in the header tank to pass through the hole under the action of gravity is plotted against the concentration of dissolved 'Polyox'. It can be seen that the additive increases the flow time, presumably by making it more difficult to stretch the vortex. (When the rod was not rotated the flow time was the same as for water.) Similar effects were obtained with solutions of the polyacrylamide 'Separan *AP* 30', and of cetrimide–alpha naphthol mixtures of a type found[6,7] to reduce turbulent drag. Guar-gum solutions, however, behaved the same as water.

The threshold shear stress for the onset of turbulent drag reduction[6] is higher for guar-gum than for the other substances quoted, so these results might be interpreted as supporting Pfenninger's hypothesis, on the assumption that in the experiments of Fig. 3 the vorticity was simply not intense enough or the stretching violent enough to produce measurable effects with guar-gum. It was

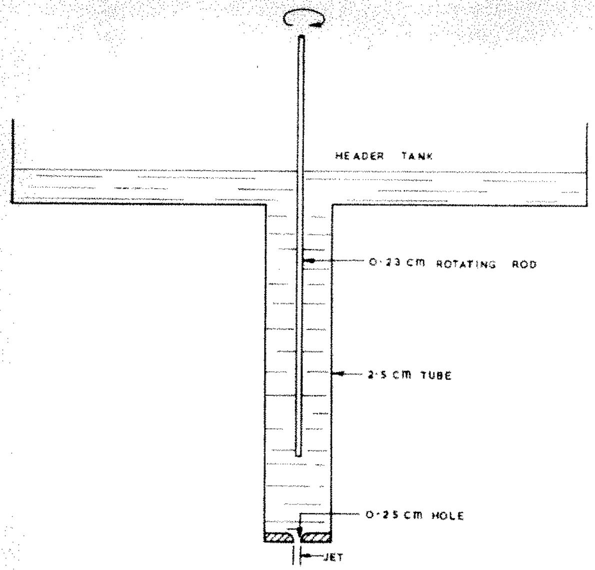

Fig. 3. Vortex stretching apparatus.

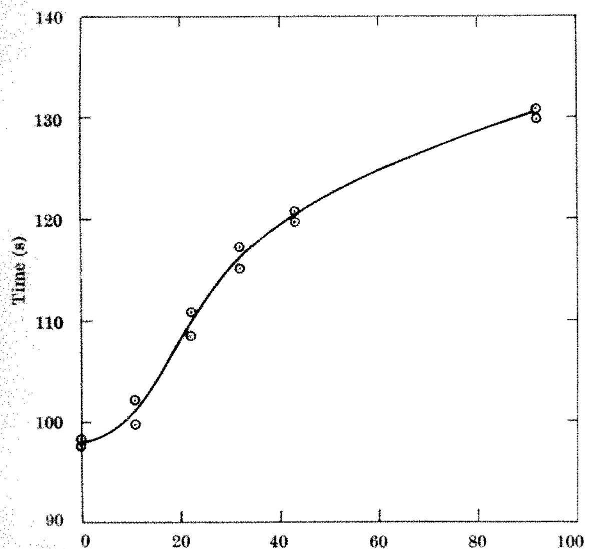

Fig. 4. Effect of 'Polyox' on flow times.

found, however, that 'Polyox' solutions, aged either by storage for about a week or by gentle pumping for a few hours, also lost the ability to slow down the vortex flow of Fig. 3. Moreover, they produced less suppression of turbulent mixing in the dye experiments of Fig. 1 than fresh solutions. (Figs. 2*a* and 2*c* are for fresh solutions.) It had previously been found[8,9] that aged solutions produce as much turbulent drag reduction as fresh ones, so this seems at first sight to show that the inhibition of vortex stretching cannot be relevant to drag reduction.

Further investigations have shown, however, that though the effects of ageing on drag reduction are indeed small at higher concentrations and high levels of the friction stress, there is some loss of effectiveness at lower concentrations around 10 p.p.m., and this loss is very marked at relatively low levels of the friction stress (for example, when the flow speed at the edge of the boundary layer, or at the centre of the pipe in pipe flow, is only of the order of 150 cm s^{-1}). At these lower levels of the friction stress the turbulence structure is coarser, so that the vorticity stretching processes perhaps approach more nearly in scale those of Fig. 3. To modify these, the presence of molecular aggregates may be needed, but when the aggregates are broken up by ageing[8] the fluid may still perhaps be able to affect the smaller, more intense stretching processes found in highly sheared turbulent flows. Thus it may be that Pfenninger's hypothesis it correct, though to establish it firmly it would be desirable to set up a vortex stretching experiment in which the length scales are smaller and the accelerations more intense than those of Fig. 3.

Interference of Sub-millimetre Waves over 450 m Path Difference

SUB-MILLIMETRE waves are attractive for metrology over long distances, because they are not much scattered by fog or cloud[1] and can be specularly reflected from ordinary machined surfaces. A device using interference over a long path difference would give a simple method of measuring small movements of a distant body and could be developed for the precise measurement of distances.

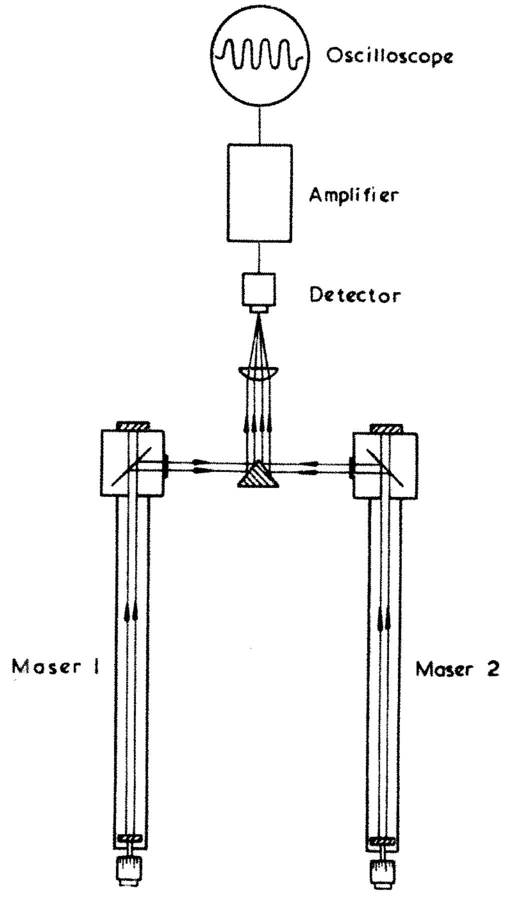

Fig. 1. Diagram of beating experiment.

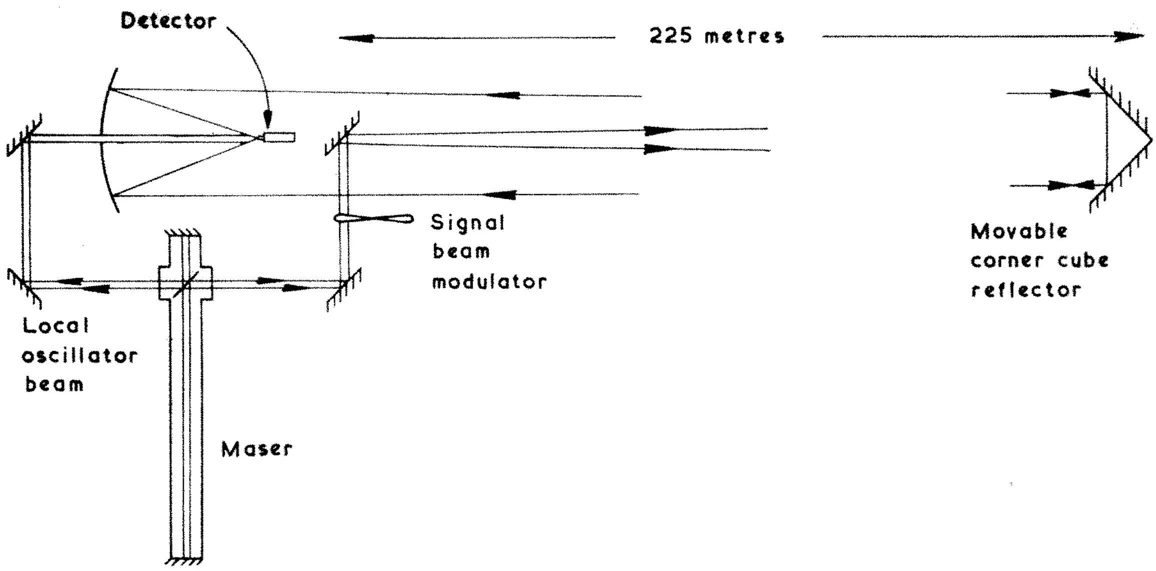

Fig. 2. Apparatus for recording interference over 450 m path difference.

Interference between beams which have traversed a large path difference requires that the radiation be confined to a narrow bandwidth, and to this end we were interested in finding the effective line width of the continuous-wave 337μ maser[2]. A preliminary experiment was carried out by beating two masers together as shown in Fig. 1, using a Putley indium-antimonide detector[3] as the non-linear mixing element.

Using single sweep operation of the oscilloscope, transient beat frequencies ranging between 20 kHz and 3 MHz were recorded, but instability of the masers causes the beat frequency to vary over periods of a few milliseconds. If, however, one of the masers is set to give maximum signal, while the second is tuned through its resonance position, the beat frequency first appears at about 3 MHz, decreases through a minimum of a few kHz and then increases again. This indicates that the maser can radiate over a band-width of a few MHz, but for short periods the emission line is much narrower.

To make a quantitative determination of the coherence length of the radiation, we built the interferometric apparatus shown in Fig. 2. A corner cube (made by Plessey Radar, Ltd.), accurately constructed to preserve phase coherence of the reflected beam, was used as the distant reflector. A maser with a dielectric film in the resonant cavity gives two beams of 337μ radiation. The "signal" beam, which is reflected back along its path by the corner cube, is modulated at 15 Hz and is mixed with the unmodulated short path or "local oscillator" beam at the Golay detector. This heterodyne method of detection as applied to submillimetre waves has been described elsewhere[4]. Interference fringes were recorded as the corner cube was slowly displaced, and have been obtained when the signal beam has travelled a total distance of 450 m. Fig. 3 shows fringes obtained at an intermediate distance.

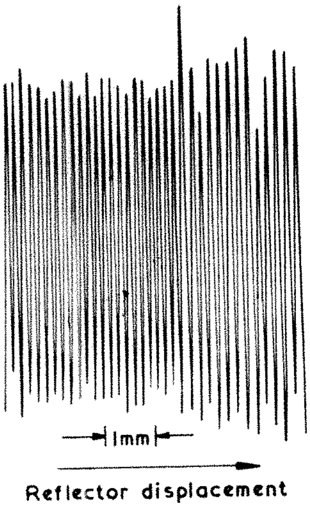

Fig. 3. Fringes recorded over 160 m path difference.

Using the expression

$$L = \frac{c}{\Delta\nu}$$

to define the coherence length L, where $\Delta\nu$ is the frequency bandwidth and c the speed of light, we see from this result that the radiation line width is not greater than 700 kHz and may well be much less. In addition, in the atmospheric conditions prevailing, phase coherence was preserved over the 450 m path.

THE SOLID STATE

Interstratified Structure formed from a Pre-heated Mica by Acid Treatments

In this study we used sericite specimens of the $2M_1$ type. The chemical composition of one of them is shown in Table 1*a*. This sample was pulverized to a fine powder in an agate mortar, heated in a platinum crucible for some time (5 min–4 h), quenched to room temperature and treated with hydrochloric or sulphuric acid. In this way the sample was easily changed, wholly or in part, into an interstratified mineral.

We found that for the sample to change into an interstratified mineral it should be heated to the temperature range of dehydroxylation. In our experiments, the duration of pre-heating did not seriously affect the amount of interstratified mineral produced, but the duration of treatment with the acids was important. The interstratified structure was formed even when the pre-heated sample was boiled for a few minutes with the acids. The longer the treatment with acids, the more interstratified mineral formed.

The product obtained after the treatment with 6 N hydrochloric acid for 1 h is shown in Table 1*b*, which gives the following structural formula

$$\begin{pmatrix}\mathrm{Ca}\ 0{\cdot}01\\ \mathrm{K}\ \ 0{\cdot}53\\ \mathrm{Na}\ 0{\cdot}17\end{pmatrix}\begin{pmatrix}\mathrm{Al} & 1{\cdot}95\\ \mathrm{Fe}^{+++} & 0{\cdot}03\\ \mathrm{Mg} & 0{\cdot}02\end{pmatrix}\begin{pmatrix}\mathrm{Si}\ 3{\cdot}30\\ \mathrm{Al}\ 0{\cdot}70\end{pmatrix}\mathrm{O}_{9\cdot99}(\mathrm{OH})_{2\cdot01}(\mathrm{H_2O})_{0\cdot76}$$

The structural formula of the original sericite was

$$\begin{pmatrix}\mathrm{Ca}\ 0{\cdot}01\\ \mathrm{K}\ \ 0{\cdot}73\\ \mathrm{Na}\ 0{\cdot}17\end{pmatrix}\begin{pmatrix}\mathrm{Al} & 1{\cdot}83\\ \mathrm{Fe}^{+++} & 0{\cdot}03\\ \mathrm{Mg} & 0{\cdot}02\end{pmatrix}\begin{pmatrix}\mathrm{Si}\ 3{\cdot}10\\ \mathrm{Al}\ 0{\cdot}88\\ \mathrm{Ti}\ 0{\cdot}02\end{pmatrix}\ \mathrm{O}_{9\cdot58}(\mathrm{OH})_{2\cdot42}$$

Under the electron microscope, the original shapes and sizes are well preserved.

The pre-heated sample, treated with 0·8 N sulphuric acid for 8 h showed a 22·7 Å reflexion (Table 2*a*), which expanded to a 23·3 Å spacing on treatment with ethylene glycol, and contracted to a 10 Å spacing when heated at 500° C for 1 h and then quenched to room temperature. This suggests that the structure consists of a nearly regular alternation of mica-like layers (*M*) 10 Å thick and hydrous mica-like layers (*H*) 12·7 Å thick, because there is a reflexion with a long spacing which has a repeat distance of 22·7 Å (10 + 12·7) and basal reflexions at submultiples of this distance. The X-ray properties are those of an "allevardite" structure with a single layer of water molecules, as reported by Brindley[1]. 'Allevardite' has been shown to be identical to 'Rectorite'[2].

a, An interstratified mineral synthesized from sericite; *b*, a sample treated with 1·2 per cent magnesium chloride solution for 1 h. Cu $K\alpha$ radiation was used.

s, Reflexions overlapped by mica reflexions.

When this product was boiled with 1·2 per cent magnesium chloride solution for 6 h, the X-ray behaviour of the sample resembled that of the regular interstratified mineral mica-montmorillonite; that is, a 25·6 Å reflexion was obtained (Table 2*b*), which expanded to a 27·2 Å spacing after treatment with ethylene glycol.

The Fourier transform method of MacEwan *et al.*[3] revealed the following probabilities of stacking: $P_M = 0{\cdot}57$, $P_H = 0{\cdot}43$, $P_{MM} = 0{\cdot}30$, $P_{MH} = 0{\cdot}70$, $P_{HH} = 0{\cdot}07$, indicating that the structure is close to the completely regular type.

It is interesting that the original sample clearly showed an endothermic peak, caused by dehydroxylation, at about 670° C, which disappeared when the sample was heated at 800° C, and reappeared at a lower temperature after treatment with acids (Fig. 1). Such rehydroxylation was also confirmed by infrared absorption spectroscopy.

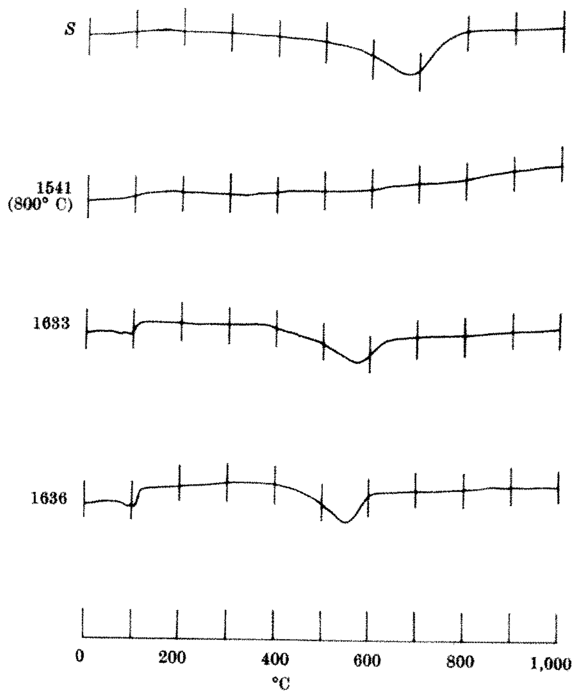

Fig. 1. Differential thermal analysis curves of the original mica sample (*S*), after the sample was heated at 800° C (No. 1541), after the pre-heated sample was treated by sulphuric acid (0·8 N) for 10 min (No. 1633), and after the pre-heated sample was treated with sulphuric acid (0·8 N) for 4 h (No. 1636).

When the physico-chemical methods used to examine the sericite were also applied to macroscopic muscovite we found that an interstratified structure of the same type had been formed in part in the flakes, but we could not confirm this for the phlogopite flakes.

As shown before[4], this is an easy method of forming an interstratified structure, and the result seems to be pertinent to the discussion of the origin of interstratified clay minerals.

CHEMISTRY

Hydrothermal Synthesis of Sodium–Mordenite in Pebble Form

MORDENITE is one of the more common low-temperature sedimentary zeolites[1]. It can be regarded as a hydration product of volcanic glasses and lavas and is, for example, formed by the crystallization of obsidian glass on exposure to a natural, acid hydrothermal solution at 230° C in a New Zealand borehole[2]. Such observations have led to the industrial development of sodium–mordenite syntheses from naturally occurring materials, particularly volcanic glasses and pumice, in well defined experimental conditions[3]. Thus synthetic mordenites are usually formed as hard or semi-hard aggregates of extremely small crystals ($\leqslant 20\mu$ diameter) after hydrothermal preparation at high *p*H (*c*. 11·5) and temperatures ranging from 100° to 260° C.

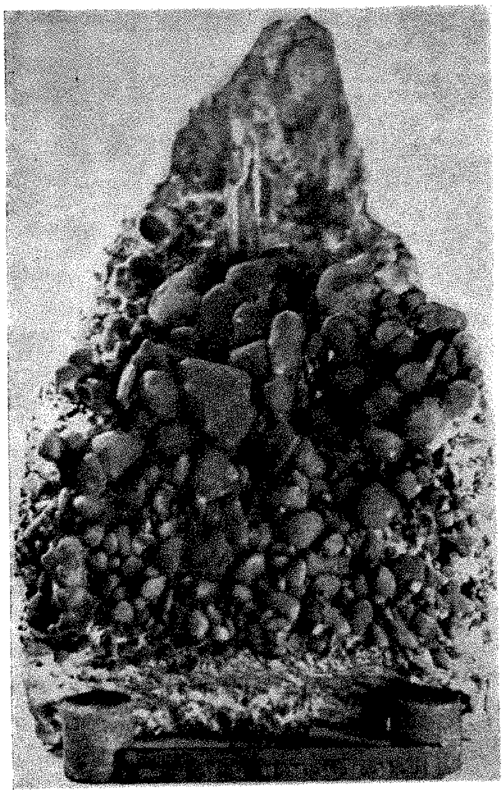

Fig. 1. "Pebbles" containing 75 per cent weight mordenite. General view looking down on mass removed from end of autoclave.

We have recently reinvestigated the hydrothermal synthesis of sodium–mordenite from finely divided pumice and aqueous "water-glasses"[3,4]. The preparative conditions were chosen to give sodium–mordenite as a single crystalline phase[4]. We found it difficult to increase the yield of mordenite above about 75 per cent weight, and the products were invariably contaminated with small amounts of albite, analcite, α-quartz and unreacted pumice. The hard crystalline masses were characterized by stratification, the mordenite being concentrated at the top in contact with the reaction mother-liquor. For this reason, the syntheses were repeated using constant agitation of the reactants at about 250 lb/in.^{2} gauge in a "rocking" autoclave. The hydrothermal products were found to be chiefly "pebbles" (Figs. 1 and 2) of from 70 to 90 per cent weight mordenite, as a single crystalline phase, set in a matrix of powdered mordenite, unreacted pumice and crystallized "water-glass". The size of the "pebbles" and their mordenite content were found to increase with the duration of hydrothermal treatment at the same pressure.

The unexpected appearance of "pebbles" in the synthesis led to speculation on their mode of origin, particularly because they slightly resembled some natural pebbles of mordenite from the type-locality, Morden, King's County, Nova Scotia[5], which had been used in earlier experiments. These pebbles were amygdales weathered from a basalt and sometimes contained needles of just sufficient breadth—about 30μ—for X-ray single crystal structure determinations.

Thin sections of the "pebbles" show a carious, fine-grained mass of overlapping anhedra of mordenite about 0·01 mm in diameter, together with dust (possibly pumice fragments), a few small anhedra of quartz and very rare fragments of pyroxene presumably unreacted portions of the starting material. The small cavities were subcircular or flattened; into them projected rectangular or acicular edges of mordenite.

No sign of a layered, concentric texture could be seen in the "pebbles", so they probably did not form by accretion. The larger ones in particular were, however, slightly moulded on one another, and on the autoclave, so that at some stage of their development they were plastic. Perhaps once nucleation of the silicate slurry started, it proceeded rapidly so that the whole passed

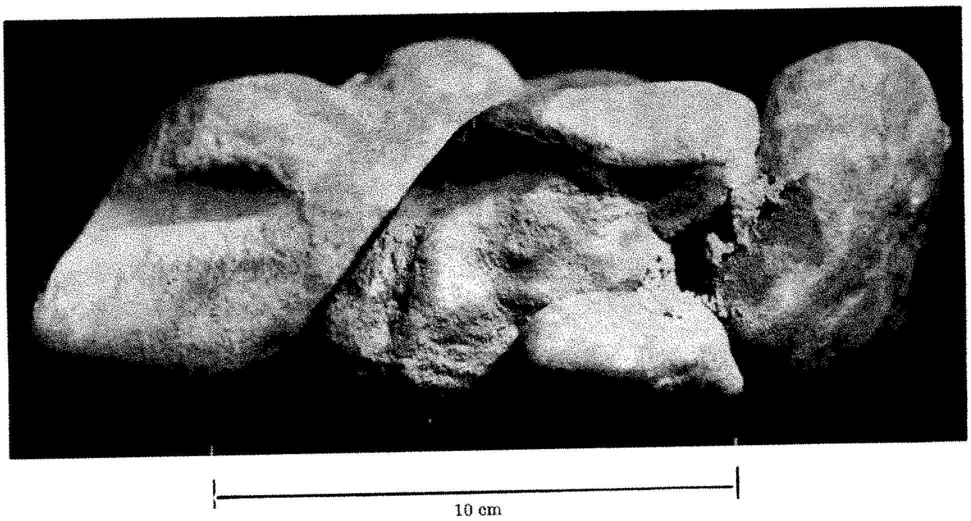

Fig. 2. "Pebbles" containing 90 per cent weight mordenite obtained by extension by 12 h of the hydrothermal treatment giving product 1 above; product moulded to part of autoclave fittings.

into a semi-solid "pasty" condition. The quite violent movement of the autoclave fragmented the mass and the "pebbles" developed by mutual attrition. They remained slightly plastic for part of the agitated cooling period, during which they sagged on to one another and moulded themselves to the autoclave fittings.

Rates of Adsorption of Wetting Agents and Detergents

ZETTLEMOYER *et al.*[1] have recently reported considerable differences in the rates of adsorption of some isomeric surfactants, for example, sodium octyl α-sulphopelargonate (I), a wetting agent, and sodium methyl α-sulphopalmitate (II), a detergent, to 'Graphon'. Both I and II have the formula $R\text{CH}(\text{SO}_3^-\text{Na}^+)\text{COO}R'$, but differ in the lengths of the chains R and R'. Type I compounds seem to adsorb three–six times faster than type II compounds. The explanations cited are a higher diffusion coefficient (D) or a faster sticking to the 'Graphon' surface for I (ref. 1).

I suggest that the important factor is the difference in the activities of the actual adsorbing species, the monomers and, perhaps, dimers, of I and II in the experiments performed. Double-chain salts such as I have lower surface activity than their long-chain isomers, presumably because of greater difficulty of interfacial adsorption[2]. Indeed, at equilibrium, II adsorbs more to 'Graphon' than I (ref. 1). Similarly, the packing needed to produce large micelles is more difficult for molecules of type I and therefore micelle formation is energetically less favourable, and the critical micelle concentration (CMC) is higher. The CMC of I, for example, is $2\cdot1 \times 10^{-3}$ M (ref. 3), obtained by the somewhat uncertain dye-spectral change method[4], while that of II is 4×10^{-4} M (ref. 3) as obtained by the dye method and $3\cdot2 \times 10^{-4}$ M from surface tensions[5]. Conductance measurements on many isomeric $R\text{SO}_4^-\text{Na}^+$ salts, with SO_4^- in different chain positions, show similar changes in the CMC (ref. 6). The differences expected between molecules of types I and II were discussed qualitatively by Hartley[2] in 1941, who showed that type I compounds can produce very low interfacial tensions, a factor closely connected with their superior wetting power.

Zettlemoyer *et al.*[1] used an initial concentration of $5\cdot8 \times 10^{-3}$ M, above the CMC for both I and II. Monomer activities change very little above the CMC and micelles are not surface active, so the "effective" activities of the adsorbing species for I and II are in the ratio of roughly 5 at $5\cdot8 \times 10^{-3}$ M. The adsorption of I should therefore be about five times faster even if there are no differences in D and rates of "sticking".

Small but significant differences may, nevertheless, exist, particularly in D. The free energies of transfer from aqueous to hydrocarbon-like media suggest that long-chain compounds in water are not tightly coiled, and probably have extended random-coil type structures[7]. On such grounds, I should have a higher D than II because of greater compactness. Experimental evidence here, however, is conflicting. D can be estimated from conductance and transference data using the Nernst–Hartley relationship[8]. The conductance data of Evans[6] suggest an overall decrease in D as SO_4^- is moved towards the middle of a chain. The data, unfortunately, show a wide scatter. On the other hand, Flockhart[9] noted a higher conductance of $\text{C}_{14}\text{H}_{29}\text{SO}_4^-\text{Na}^+$ as SO_4^- was moved from position 1 to 2 and 4. The calculated D for the 4-sulphate is higher than that for the 1-sulphate by the significant factor of 1·26.

Standard Potential of the Silver–Silver Bromide Electrode in Formamide

As part of an investigation of the behaviour of electrolytes in formamide, we have now measured the molal standard e.m.f. of the cell $\text{H}_2/\text{HBr}(m)/\text{AgBr}/\text{Ag}$ in formamide at 25° C.

Hydrogen and thermal-electrolytic silver–silver bromide electrodes were prepared according to the methods of Ives and Janz[1]. Only those silver–silver bromide electrodes with bias potentials below 150 μV were used.

Pure formamide was prepared by repeated distillation, and had a freezing point of 2·55° C and a specific conductance in the range $3\text{–}6 \times 10^{-6}$ ohm^{-1} cm^{-1}, which is in good agreement with values given in the literature[2]. Dry hydrogen bromide gas, generated by the action of bromine on tetrahydronaphthalene, was passed through formamide, in the presence of dry nitrogen. It was found possible to analyse the hydrogen bromides olutions by potentiometric titration against aqueous silver nitrate solution. The molal standard potential, E^0, was determined by extrapolating to zero molality the function E', given by

$$E' = E + 2\cdot303 \times 2RT/F\ (\log(m) - A\sqrt{m})$$

where the symbols have their usual meanings. The value of the Debye–Hückel constant A for formamide at 25° C is 0·3286 $(\text{moles/kg})^{-\frac{1}{2}}$. The values of E' are shown plotted against m in Fig. 1. The best straight line, fitted

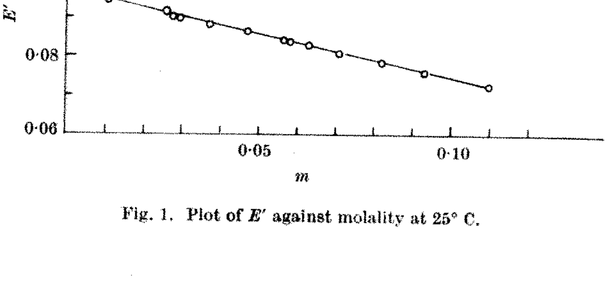

Fig. 1. Plot of E' against molality at 25° C.

using a least squares treatment, gives the intercept, E^0, as 0.0967 V with a root mean square deviation of 0.0007 V.

Enhanced Catalytic Activity of Platinum Electrodes resulting from Cathode Pretreatment

A recent report[1,2] describes the effect on Raney platinum electrodes of cathodic pretreatment in 10N H_2SO_4. Current-voltage curves for the oxidation of formic acid in 3N H_2SO_4 before and after pretreatment were compared and the enhanced currents measured for the treated electrodes were attributed to an adsorbed layer of sulphur formed by deposition during the cathodic pretreatment. This is surprising because the inhibiting effect of sulphur adsorbed on platinum on many other surface reactions and electrode reactions is well known and was observed by Faraday[3]. Enhanced catalytic activity was also observed[1,2] by using electrodes pretreated with gaseous hydrogen sulphide at high temperatures and with electrodes cathodically polarized in solutions of selenium oxide in dilute sulphuric acid. Extended cathodic pretreatment in 10 N H_2SO_4 yielded a less active electrode. Here, the sulphur was said to have formed a monolayer.

At our laboratories, measurements have been made on bright platinum electrodes in a half cell arrangement with a hydrogen electrode as a reference electrode in stirred solutions of formic acid in 2 N H_2SO_4. Electrochemical pretreatment steps, similar to those used by Gilman[4], ensured that the electrode was in a reproducible state. The most important part of this treatment consisted of holding the electrode at 1.55 V for 30 s and at 0.05 V for a further 15 s. The steady state current-voltage curve for the oxidation of formic acid was measured (Fig. 1). Cathodic pretreatment in 10 N solutions of three strong acids (H_2SO_4, $HClO_4$ and HNO_3), stirred by bubbling pure nitrogen over the electrode, was then carried out. This treatment consisted of holding the electrode at −0.25 V for an arbitrary time (90 s). After the electrode had been washed its potential was held at +50 mV for a few seconds before measurement of the current-voltage curve for formic acid oxidation (Fig. 1). The enhanced oxidation rate (increased currents at lower potentials) remained stable provided the electrode potential was not increased beyond 600 mV for long periods of time (that is, more than 4 min).

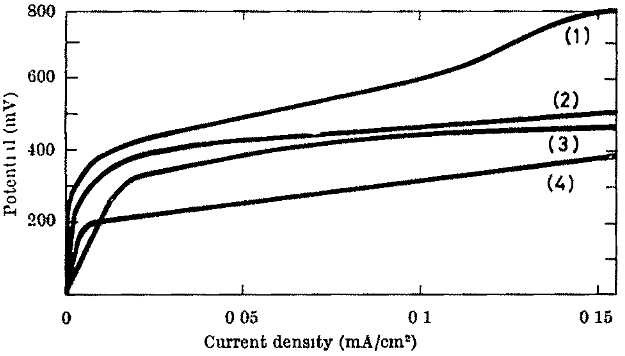

Fig. 1. Anodic oxidation of formic acid in 2 N H_2SO_4 on bright platinum electrodes. Curve 1, results for untreated electrode, curves 2, 3 and 4, results for electrodes "activated" in perchloric acid, sulphuric acid and nitric acid, respectively.

The form of these results agrees with that of those previously obtained by the other workers for activation in sulphuric acid[1,2]. The extension of the measurements to other strong acids, however, leaves some doubts as to the interpretation of these effects.

There are several possible explanations. Cathodic pretreatment might simply reduce any remaining "oxide" on the platinum surface; such a reduction could also be effected by hydrogen sulphide at high temperatures. It may be, however, that some hydrogen remains on the surface of the platinum at potentials where hydrogen is not normally expected to be present[5]. If so, the catalytic activity would be altered, for there would no longer be a true platinum surface. Furthermore, it could be that sorption layers are formed in which the ions NO_3^-, ClO_4^- and SO_4^{2-} are adsorbed on the platinum surface in some partially reduced state in such a way that they catalyse the oxidation of formic acid by a redox process. It is also conceivable that this type of layer could be formed by chemical action of hydrogen sulphide on "platinum oxide". The lower activity of the Raney electrodes which had undergone extended cathodic polarization was probably caused by adsorbed impurities or even by inhibition by sulphur.

I thank A. F. Douglas for help with the experimental measurements.

Bistability caused by Substrate Inhibition of Peroxidase in an Open Reaction System

Several authors have suggested that more than one stable stationary state exists in an open homogeneous reaction system, and this suggestion has served as a basis for speculative explanations of various biological phenomena[1-4]. Although bistability is well known in open heterogeneous chemical reaction systems, as for example an electrolysis cell with a passivable electrode[6], it seems that bistability has never been observed in an open homogeneous system. This communication describes such a case.

The reaction used in the experiment is the oxidation of NADH by O_2 catalysed by horseradish peroxidase. This reaction was studied in an open system by Yamazaki *et al.*[7,8], who found the reaction to be autocatalytic and that damped oscillations in the oxygen concentration of the solution may occur when oxygen is supplied continuously by bubbling with a mixture of oxygen and nitrogen. Although this is not explicitly stated by Yamazaki *et al.*, it seems from their experimental results that the oxidation of NADH is inhibited by oxygen, because at high oxygen concentrations the enzyme is converted to an inactive form spectrophotometrically identified as complex III. This substance was originally discovered by Keilin and Mann as a reaction product of peroxidase and H_2O_2 (ref. 9).

Substrate inhibition is one of the possible mechanisms which can lead to bistability in an open system, as predicted by Sel'kov[10] and Higgins[11]. Consider, for example, the following formal reaction scheme suggested by Higgins[12]

$$S+E\xrightarrow{k_1}ES$$

$$ES\xrightarrow{k_2}E+P$$

$$S+ES\underset{k_4}{\overset{k_3}{\rightleftharpoons}}ES_2$$

where a reversible reaction between the substrate and the enzyme–substrate complex to form an inactive complex (ES_2) is added to the classical Michaelis–Menten scheme The steady state rate of consumption of the substrate according to this scheme is

$$-\frac{ds}{dt}=\frac{k_1e_0s}{1+\dfrac{k_1}{k_2}s+\dfrac{k_1k_3}{k_2k_4}s^2} \qquad (1)$$

where e_0 is the initial enzyme concentration It is assumed that the reaction occurs in a stirred solution which can exchange substrate by diffusion with a reservoir of constant concentration The rate of transport of substrate into the reaction solution is then given by

$$\frac{ds}{dt}=K(s_x-s) \qquad (2)$$

where K is a constant and s_x is the concentration of the substrate in the reservoir For the open system to be in a stationary state, the rate of consumption of substrate given by (1) must be equal to the rate of transport of substrate into the reaction solution given by (2) For positive rate constants the curve described by (1) must always have a form as shown in Fig 1 Such a curve can have one (*A*) or three (*B*, *C* and *D*) intersections with the straight line given by (2) depending on the slope and position of this line In the case of only one point of intersection this point corresponds to one stable stationary state of the system If there are three intersections, one of them (*C*) corresponds to an unstable stationary state and the two others correspond to stable stationary states

In the present work, the peroxidase catalysed oxidation of NADH by O_2 was studied in an open system slightly different from that of Yamazaki *et al* The experiments were performed in a 1 × 1 × 4 cm cuvette in a double beam spectrophotometer The light absorption was measured at 418 mμ, where complex III has an absorption maximum The wavelength of the reference light was 615 mμ, which is an isosbestic point of the peroxidase-complex III couple The oxygen concentration in the liquid was measured polarographically by a vibrating platinum electrode A mixture of O_2 and N_2 was blown at a constant rate on the surface of the solution The vibration of the electrode caused an efficient stirring and a suitable supply rate of oxygen to the solution could be obtained without bubbling the gas mixture into the solution Oxygen was continuously supplied to the system but NADH was not The initial concentration of NADH was made so high, however, that the decrease of NADH concentration during the experiment was not significant Fig 2 describes the reaction system schematically

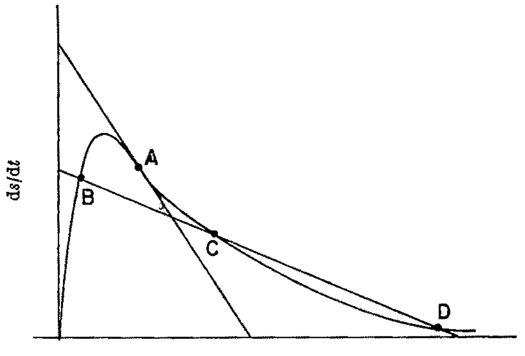

Fig 1 Characteristic curve of substrate inhibited enzyme reaction For explanation see text

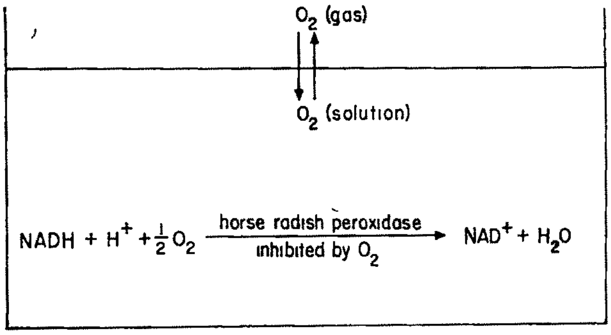

Fig 2 Schematic representation of experimental system yielding results shown in Fig 3

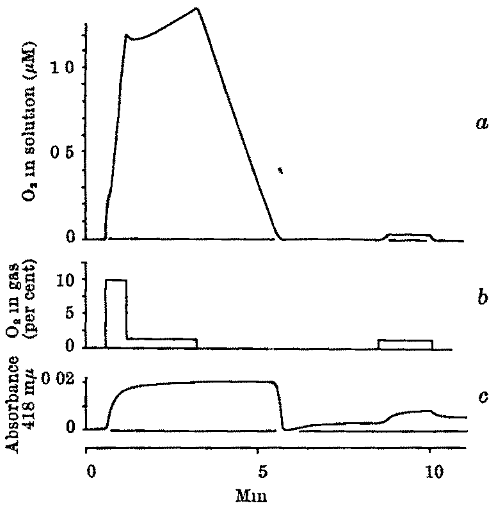

Fig 3 Simultaneous measurement of oxygen concentration (*a*) and light absorption at 418 mμ (*c*) of 0 4 μM horseradish peroxidase (Boehringer und Soehne) and 1 4 mM NADH in 0 07 M phosphate buffer at pH 5 5 Oxygen was supplied to the solution by a mixture of O_2 and N_2 blown on the surface at a rate of 10 ml /s The setting of the oxygen content of the gas mixture is indicated in (*b*)

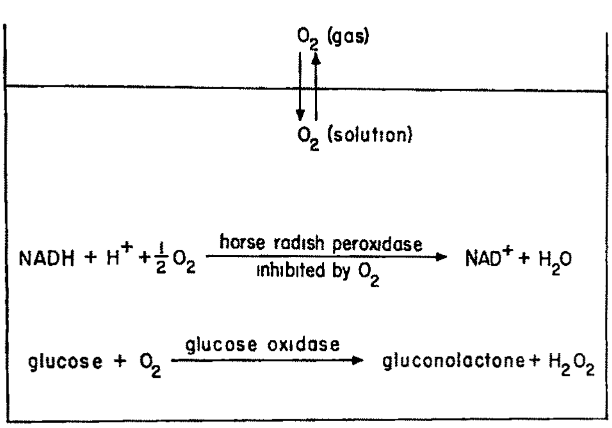
Fig 3 shows the simultaneous measurements of the oxygen concentration in the solution (*a*) and the light absorption at 418 mμ (*c*) when the oxygen content of the gas mixture (*b*) was increased from zero to a constant value, in one case after an initial pulse and in another case without such a pulse It is seen that in the first case the oxygen concentration in the solution increased rapidly during the pulse and continued to increase more slowly as long as the oxygen content of the gas mixture was kept on the constant value When the oxygen in the gas was turned off, the oxygen concentration of the solution fell slowly to zero In the second case, when the oxygen content of the gas mixture was set at the same constant value as before but without an initial pulse, the oxygen concentration in the solution increased to a very low level where it remained constant until the oxygen in the gas was turned off, after which it fell to zero

In the experiment illustrated in Fig. 3 a stationary concentration of oxygen in the solution was not reached in the first case when an initial pulse of oxygen was used It was found in similar experiments that a high stationary concentration of oxygen could be obtained, but to show this it was necessary to use a scale of measurement on which the low stationary concentration of oxygen could not be recorded The very large difference between the two stationary oxygen concentrations indicates that there is a large difference between the activities of the enzyme in the active and the inhibited states It was anticipated that the distance between the two stationary oxygen concentrations could be decreased by the addition of a second oxygen consuming reaction which is not inhibited by oxygen It was found that the addition of the glucose oxidase catalysed oxidation of glucose to the reaction system as shown in Fig 4 had the anticipated effect The production of H_2O_2 as an end product in the oxidation of glucose did not seem to play any important part in the reaction system



O_2 (gas)
O_2 (solution)
$NADH + H^+ + \frac{1}{2}O_2 \xrightarrow[\text{inhibited by } O_2]{\text{horse radish peroxidase}} NAD^+ + H_2O$
$\text{glucose} + O_2 \xrightarrow{\text{glucose oxidase}} \text{gluconolactone} + H_2O_2$

Fig 4 Schematic representation of experimental system yielding results shown in Fig 5

Fig 5 shows an experiment similar to that shown in Fig 3 except that glucose and glucose oxidase were added to the solution besides peroxidase and NADH It is seen that a high stationary concentration of oxygen in the solution was obtained when the constant oxygen content of the gas mixture was preceded by a pulse The stability of the high stationary oxygen concentration is evident from the fact that it is approachable from both sides The low stationary concentration of oxygen which is obtained at the same constant oxygen content of the gas mixture when an initial pulse is not used is also approachable from both sides When a small oxygen pulse was applied after the low stationary oxygen concentration was reached, the oxygen concentration in the solution increased a little but fell back to the original value When the pulse was a little higher, however, the system was triggered into the high oxygen state

The light absorption measurements in Figs 3 and 5 show that the admission of oxygen to the solution leads to the formation of a substance absorbing at 418 mμ This substance can have two different stationary concentrations at the same oxygen content of the gas mixture A high oxygen concentration in the solution, whether stationary or not, is accompanied by a high stationary concentration of the light absorbing substance At a low stationary oxygen concentration in the solution the light absorbing substance has a low stationary concentration In the low oxygen state the concentration of the absorbing substance varies with the concentration of oxygen in the solution The autocatalytic character of the NADH oxidation reaction is indicated by a lag time between the beginning of the increase of the oxygen concentration in the solution and the beginning of the increase of the light absorption Also it is observed that the rate of increase of oxygen concentration during the initial pulse exhibits a deflexion when the light absorption is increasing These phenomena are more evident at lower DPNH concentrations and higher pH The fact that the reaction is autocatalytic is not essential for the bistability

These findings are consistent with the assumption that the light absorbing substance is an inactive form of the enzyme, presumably complex III, and that at high oxygen concentrations the enzyme is almost completely converted to the inactive form, whereas at low oxygen concentrations a partial conversion, to a degree determined by the oxygen concentration, takes place It should be noted that peroxidase alone does not react with oxygen to form complex III In the present system, the complex is only formed along with the oxidation of NADH

It may be questioned whether the bistability observed in the present experimental system has any physiological relevance Of interest in this connexion is the finding by Harrison and Pirt[13] that the respiration of a continuous culture of *Klebsiella aerogenes* is inhibited by oxygen and that abrupt transitions between high and low oxygen concentrations in the liquid take place at certain values of the oxygen content of the mixture of oxygen and nitrogen used to supply oxygen to the culture Such phenomena in the continuous bacterial culture may be caused by a respiratory enzyme which is inhibited by oxygen, as is the horseradish peroxidase, but a more

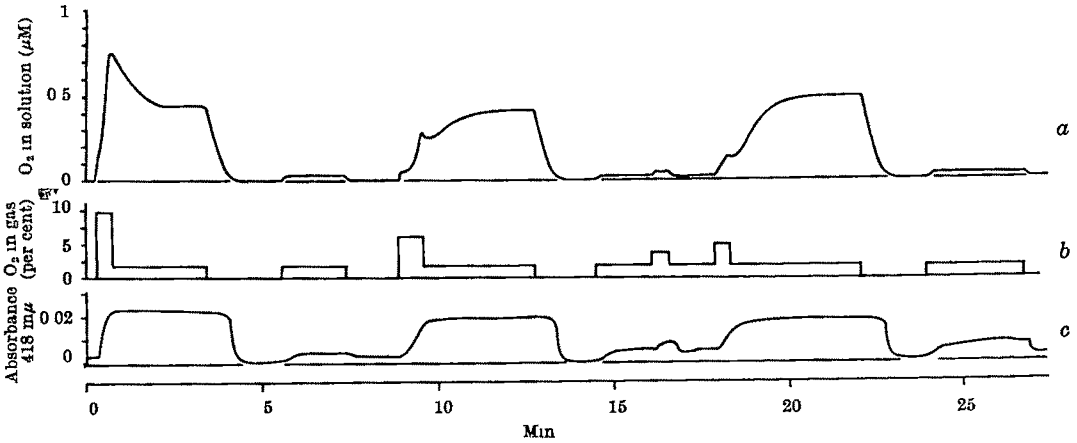


Fig 5 Experiment similar to that in Fig 3 except that 3 5 μg/ml glucose oxidase and 17 mM glucose in addition to 0 4 μM peroxidase and 7 mM NADH are present in the solution

indirect control of the respiration rate by oxygen is also possible

BIOCHEMISTRY

Sub-unit Nature of Catalase Compound II

THE absorption spectrum of catalase compound II is well established and provides the principal basis for the characterization of this species The nature of the reactions involved in the conversion of catalase to compound II is not well understood, but it is clear that compound II plays a very important part in the reversible deactivation of catalase by its substrates Although there has been no suggestion in the literature that the formation of compound II involves a major disruption of the catalase molecule, recent kinetic studies in this laboratory[1] suggested that compound II may be a sub-unit species This compound is sufficiently stable to permit a direct test of this idea by sedimentation velocity studies in the analytical ultracentrifuge

The catalase used in our experiments was prepared from *M lysodeikticus* and had an activity[2] of 6 5 × 10^{7} M^{-1} s^{-1} and an RZ value of 0 8 sedimentation velocity experiments showed no lower molecular weight impurities Catalase was partially converted to compound II by the addition to catalase solutions (~ 10^{-5} M, phosphate buffer *p*H 7·0) of either several very small amounts of H_2O_2 (allowing the catalatic reaction to subside after each addition) or, in much milder conditions, by a single addition of dilute aqueous alkyl hydroperoxide solution The results obtained were independent of the mode of formation of compound II The absorption spectra of the solutions were time invariant for several hours and these measurements permitted calculation of the percentage of compound II using the data of Chance and Herbert[3]

Fig 1 shows the sedimentation velocity pattern obtained with the Beckman Model E Ultracentrifuge, from a catalase solution containing 17 5 per cent compound II by spectrophotometric estimation, the faster peak ($S_{20,w}$ = 10 7 *S*) corresponds to catalase (ref 4, S_{20} bacterial catalase = 11 0 *S*) The fraction of slower moving material ($S_{20,w}$ = 2 7 *S*) corresponded well with the percentage of compound II in the solution (for example, 15 per cent slower moving material for the experiment shown in Fig 1, corrected for sectorial dilution) We therefore assign the slower peak to compound II and, if compound II resembles a globular protein, the reduced *S* value implies a much lower molecular weight than that of catalase Using the method of Van Holde[5], we have calculated a diffusion coefficient for compound II of 5 4 × 10^{-7} cm^{2} s^{-1}, which yields a molecular weight of about 5 × 10^{4} (compare ref 4, bacterial catalase 2 3 × 10^{5}) A more detailed quantitative characterization of compound II is in progress and other catalase compounds are also being investigated

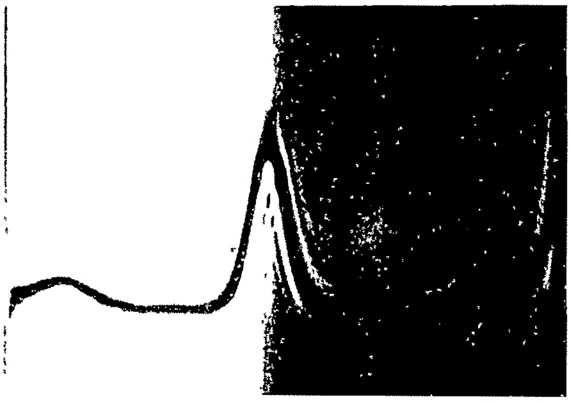

Fig 1 Sedimentation velocity pattern of mixture of catalase and compound II Speed 60,000 r p m , *T* = 22° C, photograph taken 31 min after reaching full speed, bar angle 60° Sedimentation occurs to the right

The occurrence of catalase sub-units has been reported in extreme conditions[6] and after lyophilization[7] Caravaca *et al* [8] have shown that a hepatocatalase sub-unit, which lacks significant catalatic activity, is a powerful peroxidase *in vitro* They have also shown that, *in vivo*, this sub-unit may be of value in the prevention of induced atherosclerosis[9] Our result that compound II is a sub-unit species opens a new chapter in fundamental studies of the catalase system We believe that a variety of sub-unit species play important parts in catalase action and our evidence to support this more general proposition will be published in detail elsewhere

We wish to thank Professor J Baddiley for making available facilities for the growth and manipulation of bacteria in the SRC Microbiological Chemistry Research Unit Laboratories, Dr A L Davison for assistance with microbiological work and Professor A S Brill for advice on the purification of bacterial catalase We also thank the SRC for a studentship (to A S)

Evidence that there are Two Forms of Fluoride in Human Serum

IT has been assumed that there is only one form of fluoride in serum, the inorganic F ion It would therefore seem that either the value for serum fluoride which I found (1 μM) (refs 1 and 2) or that found by Singer and Armstrong (7 5 μM) (ref 3) must be in error While the diffusion method of Singer and Armstrong has been shown to produce erroneous values, the same cannot be said for their ashing and distillation procedure The evidence that the serum fluoride is about 1 µM in a fluoridated community does not rule out the possibility that more fluoride could be made available from serum by ashing, it only indicates that the fluoride in serum able to exchange with added radioactive fluoride can be measured and is 1 µM

To test the hypothesis that ashing makes more fluoride available, 10 ml samples of serum were ashed with a fixative and the fluoride was diffused from the ash at room temperature The fixative, 5 ml of a solution of 1 M $MgCl_2$ and 1 mM Na_2CO_3, was shown in experiments using standard solutions or serum to retain 94–99 per cent of radioactive fluoride at an ashing temperature of 600° C for 3 h The fluoride present in the neutralized diffusate was measured by the fluoride electrode[4] and then by the morin–thorium reagent[1] The readings in serum were compared with bracketing standards which had been similarly handled Thus the blanks, standards and samples had identical ionic strengths and pH for measurement by the fluoride electrode

As shown in Table 1, there is excellent agreement between the findings with the fluoride electrode and those employing the morin–thorium reagent The values obtained are about 5 µM, which are considered by Singer and Armstrong to be within normal limits by their ashing procedure, but are much greater than those shown in brackets, found by my diffusion method (25° C), which are all less than 1 µM The blank value from diffusion was usually about 0 15 µM and the blank from the fixative and ashing 0 8–1 0 µM, that is, 0 2 of the amounts of fluoride being analysed

Using radioactive fluoride as a control of completeness of recovery, the results of the fluoride electrode were compared with those of the morin–thorium reagent after direct diffusion of fluoride from 10 ml aliquots of serum Identical values (0 9 µM) were obtained, the details are being prepared for publication elsewhere as part of the validation of the new method Comparisons of measurements of serum fluoride with the fluoride electrode and with the morin–thorium reagent after diffusion at 60° C as recommended by Singer and Armstrong show a marked discrepancy, 1 5 ± 0 5 µM and 10 3 ± 2 2 µM, respectively (eight samples in each, $\pm S\ E$), confirming earlier findings of false positive values generated by diffusion at 60° C

Commercial human gamma globulin was included in the third experiment of Table 1 because it provides a control against the possibility that ashing of protein allows more contamination either from the platinum crucibles or from the air Four ml of the gamma globulin solution was used/sample because the protein was more concentrated (16 5 per cent) than the protein in serum (7 per cent) Small quantities of fluoride (about 1 µM) were found, much less than the increment following the ashing of serum or plasma

Preliminary data on the distribution of the extra fluoride in serum are shown in Table 2 The morin–thorium reagent was used to measure the fluoride after diffusion at 25° C either directly or after ashing Extra fluoride seems to be associated with the albumin and cannot be ultrafiltrated Concentrating the serum proteins concentrated the extra fluoride in proportion

Table 1 COMPARISON OF FLUORIDE CONCENTRATION (µM) AFTER ASHING USING MORIN–THORIUM REAGENT AGAINST FLUORIDE ELECTRODE

	M–T reagent	F electrode
Exp 1 Serum	5 9	5 8
(0 8 µM)*	4 4	4 5
	5 5	5 6
Exp 2 Plasma	4 8	4 0
(0 5 µM)*	4 3	3 7
	4 4	3 7
Exp 3 Serum	4 3	4 2
(0 8 µM)*	3 9	4 2
	4 2	4 5
Gamma globulin	0 8	1 5
16 per cent protein (0 8 µM)*	1 0	1 5

* Average values from non-ashed samples by my method

Table 2 FLUORIDE CONCENTRATION (µM) IN VARIOUS COMPONENTS OF SERUM

		Ashed	Not ashed
Exp 4	Gamma globulin	1 8	1 0
	16 per cent protein	1 0	0 6
	Albumin	8 8	1 0
	25 per cent protein	8 5	0 9
	Plasma	3 8	0 6
	7 per cent protein	3 5	
Exp 5*	Serum ultrafiltrate	1 3	1 1
		1 2	1 1
	Serum, volume reduced to	8 3	0 9
	one half by ultrafiltration	9 5	0 9

* Same serum used for Exp 3 and 5

These results are consistent with the hypothesis that there are two forms of fluoride in serum, exchangeable and non-exchangeable

In 1950, Smith, Gardner and Hodge[5] found normal values of 1 7 µM for serum fluoride in a fluoridated community, implying that they also were measuring only exchangeable fluoride They distilled fluoride from blood with H_2SO_4 at 135° C and then ashed the distillate[6] If in fact there is a non-exchangeable fluoride in serum, it did not break down or diffuse under these conditions, implying a large stable molecule These findings are consistent with the presence of a fluorocarbon molecule

There seems to have been very little consideration of this possibility in any biological work Peters[7] found that fluoroacetate is synthesized by certain toxic plants, but that it is not a general phenomenon His work, however, leaves open the possibility of other forms of organically bound fluorine

I thank Mrs Joy Howe and Mr C F Ning for technical assistance This work was supported by a grant from the US National Institutes of Health

New Form of Diphtheria Toxin

ULTRACENTRIFUGAL studies have shown that purified diphtheria toxin is a single protein with a molecular weight of 64,500 and an $S_{20,w}$ of 4 2 (ref 1) In this communication, I report experiments with a sample of toxin that contains the 4 2 S molecule, and an unusual species with a higher sedimentation constant These two toxin molecules have been separated by disc electrophoresis on polyacrylamide gels, by ultracentrifugation and by chromatography on a thin layer of 'Sephadex *G*-100'

Partially purified diphtheria toxin (supplied by Mr Leo Levine of the Massachusetts Department of Public Health, Boston) was further purified by fractionation with ammonium sulphate The fraction obtained between 45 and 60 per cent saturated ammonium sulphate was chromatographed on DEAE-cellulose as previously described[2] The purified toxin thus obtained contained 60 *MLD*/Lf and 2 6 µg of protein/Lf Its specific activity compares favourably with that reported by others[1,3] for highly purified toxin preparations

Electrophoresis on polyacrylamide disc gels was performed at room temperature The 7 5 per cent polyacrylamide gels were run in a *tris* glycine buffer, pH 8 9, at 3 3 mA/tube for 2 h[4] After electrophoresis, the gels were fixed with 10 per cent trichloroacetic acid (TCA) and

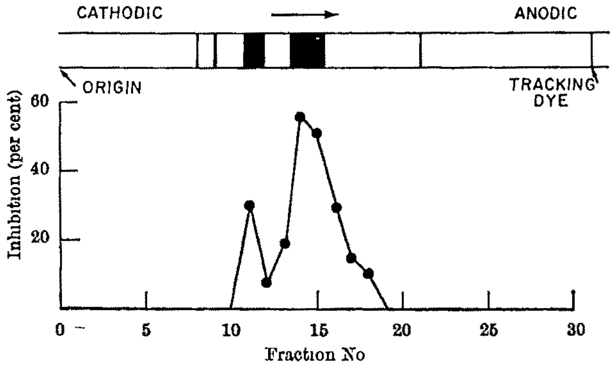

Fig 1 Line drawing of a disc electrophoresis of purified diphtheria toxin run on a 7 5 per cent polyacrylamide gel and stained as described in the text A duplicate, unstained gel was sliced into thirty thin fractions and the protein in each fraction eluted into a phosphate buffer containing BSA An aliquot of each eluate was tested for its ability to inhibit poly-U-directed incorporation of ^{14}C-phenylalanine into TCA precipitable material in a cell-free system derived from rabbit reticulocytes The results are expressed in terms of the percentage inhibition of the level of ^{14}C-phenylalanine incorporation into TCA precipitable material exhibited by the control to which no toxin or eluate was added

stained with Coomassie blue[5] As shown in Fig 1, two principal bands and three lesser bands are visible Eighty per cent of the toxic activity can be recovered from a duplicate, unstained gel after electrophoresis The gel was first chilled to 0° C and sliced into approximately thirty thin sections Toxin was eluted by shaking each slice overnight at 25° C in a 2 mM potassium phosphate buffer, pH 7, containing 100 µg/ml bovine serum albumin (BSA) The eluate from each fraction was tested for its ability to inhibit incorporation of amino-acids in a cell-free rabbit reticulocyte system[2,6] All assays were performed in the presence of 0 03 mM NAD, which is needed for toxic activity in the cell-free system[2,6] As shown in Fig 1, there are two peaks of inhibitory activity (fractions 11 and 14) which correspond to the two heavily stained bands on the gel A comparison of fractions 11 and 14 shows that fraction 14 not only stains more darkly than fraction 11 but also contains more inhibitory activity The eluates from fractions 11 and 14 were also tested for their ability to kill guinea-pigs The results of these routine *MLD* determinations showed that the ratio of *MLD*/Lf of each fraction is approximately that of the mixture

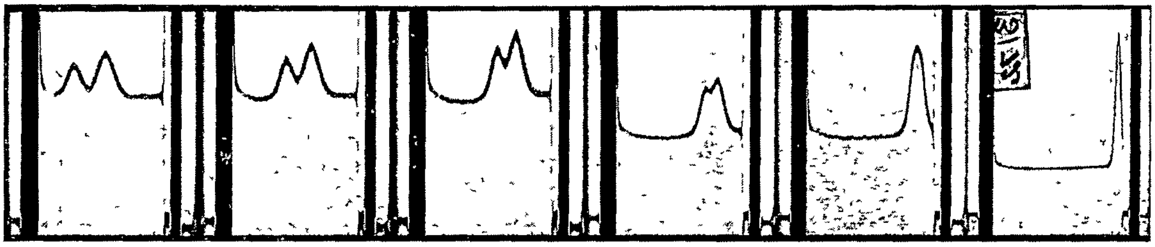

Fig 2 Schlieren patterns from ultracentrifugal sedimentation of purified diphtheria toxin, 8 mg/ml, in 0 01 M potassium phosphate buffer, pH 7 From right to left 19, 35, 51, 67, 83 and 99 min after running at 60,000 r p m

Ultracentrifugal analysis of a solution containing 8 mg/ml diphtheria toxin in 0 01 M potassium phosphate buffer, pH 7, was performed at 60,000 r p m and 25° C As shown in Fig 2, this preparation of toxin exhibits two peaks with uncorrected sedimentation constants of 4 6 and 6 8 These peaks sediment independently of one another The areas under the peaks show that the heavy component is present in lower concentrations than the light one The ultracentrifugal pattern is not altered by the presence of 1 5 mM NAD

Chromatography of this preparation of toxin was performed on a thin layer of 'Sephadex *G*-100' superfine[7] Approximately 40 µg of toxin was spotted on the 'Sephadex' thin layer which was developed with 0 01 M *tris* buffer, pH 7 1, for 6–8 h at 25° C On completing the chromatography, the 'Sephadex' was overlaid with a sheet of dry Whatman 3 *MM* filter paper After 10 min at 25° C, the paper was dried and sprayed with ninhydrin As shown in Fig 3, the toxin was resolved into two ninhydrin-positive components The spot obtained from the slow component was always darker than that from the fast one The fast component in chromatography and in ultracentrifugation thus probably corresponds to the slow one in electrophoresis

A second sample of toxin obtained from the Massachusetts Department of Health and purified in the same way as the preparation described gave identical results on 'Sephadex' On the other hand, a sample of crude toxin supplied by Dr H Devlin of Parke, Davis and Co showed only the usual slow component after chromatography on 'Sephadex *G*-100' (Fig 3)

The unusual, fast component can be completely converted to the slow one by treating the toxin with the sulphydryl reagent, dithiothreitol (DTT) A sample of toxin (250 µg) was incubated overnight at 25° C in 0 01 M *tris* buffer, pH 7 3, containing 0 33 M DTT and 0 08 M EDTA After this treatment, only the slow component was detected following chromatography on 'Sephadex *G*-100' (Fig 3) The fact that the fast component was converted to the slow one by DTT implies that it may be a polymer composed of two or more 4 2 S components held together by disulphide bonds Raynaud *et al*[1] have shown that 4 2 S toxin has no free sulphydryl groups

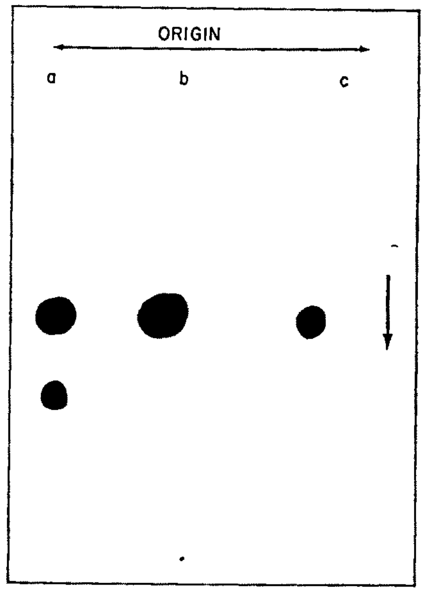

Fig 3 Chromatography of diphtheria toxin on a 12 × 20 cm thin layer of 'Sephadex *G*-100' superfine (*a*) Purified toxin obtained from the Massachusetts Department of Health, (*b*) toxin from (*a*) that has been treated overnight with 0 33 M DTT and 0 08 M EDTA before being chromatographed, (*c*) toxin obtained from Parke, Davis and Co

but does have two disulphide bonds. It is possible that in certain conditions one or both of these disulphides is able to form a disulphide bridge between two 4.2 *S* molecules.

The unusual, heavy form of toxin reported here might have been formed as a result of mutation either in the *Corynebacterium diphtheriae* or in its lysogenic phage, or as a result of unusual growth conditions during toxin synthesis.

I thank Dr W. Carroll for performing ultracentrifugal analyses, Dr M. Becker for help in performing electrophoreses and Dr E. Maxwell for helpful suggestions. Amino-acid Composition of "Tubulin" constituting Microtubules of Sperm Flagella

PHYSICOCHEMICAL characterization of components of flagella and cilia is essential for an understanding of the mechanisms underlying flagellar and ciliary movement. The so-called "9+2" fibres (microtubules) are one of the chief ultrastructures in both flagella and cilia, and can be isolated with minimum contamination of other components[1,2].

Microtubules were obtained from sperm flagella of the sea-urchins *Pseudocentrotus depressus* and *Anthocidaris crassispina*. Semen was collected by injecting 0.5 M KCl into the body cavity, and diluting with artificial sea water free from calcium and magnesium. The suspension of sperm was subjected to mild sonication, and centrifuged at 900*g* for 10 min to separate detached flagella from heads and mid-pieces. The precipitate was washed with this solution, and the combined supernatants were centrifuged first at 900*g* for 10 min to remove any remaining heads and mid-pieces, and then at 15,000*g* for 10 min to collect flagella. At this stage, the preparation showed almost no cytochrome oxidase activity. The isolated flagella were treated with a 0.5 per cent digitonin solution to remove cell membranes, centrifuged at 20,000*g* for 10 min and then washed twice with 30 mM *tris* HCl, *p*H 8.2, and 2.5 mM $MgCl_2$ solution. The microtubules were isolated from the flagellar preparation by two different methods—dialysis of the preparation against 1 mM *tris* HCl, *p*H 8.2, and 0.1 mM EDTA solution for 2 days, followed by centrifuging at 100,000*g* for 15 min and extraction of the preparation with Weber–Edsall solution for 2 days, followed by centrifuging at 20,000*g* for 10 min. The precipitates obtained by these two methods were found under the electron microscope to consist exclusively of microtubules. The isolated microtubules were then suspended in 10 mM *tris* HCl, *p*H 8.2. The suspensions were dialysed against distilled water, lyophilized and kept in a deep freezer until amino-acid analyses were carried out.

Table 1 shows the results of the analyses of the component protein of microtubules. The amount of tryptophan was estimated from the ultraviolet absorption spectra of the protein solutions[3]. Half cystine was determined by measuring the amount of cysteic acid obtained by performic acid oxidation before hydrolysis with 6 N HCl. No significant difference was observed between the results obtained by the two methods, or between the results obtained with the two different species. The amino-acid residues accounted for 75–80 per cent of the total weight of the samples.

If we take the amount of half cystine and of tryptophan as a unit, the minimum molecular weight of the protein is calculated to be about 7,000. Using the protein isolated from the mitotic apparatus of sea-urchin eggs, Sakai[4] found that the dimer (3.5*S* particle) of the protein contained six SH groups and one S–S group. The spindle fibres of the mitotic apparatus are also microtubules, and are similar to the "9+2" micrtubules of flagella and cilia. When the minimum molecular weight is multiplied by eight, the resulting value is about 56,000. The molecular weight of the 3.5*S* particle of the mitotic apparatus was reported to be 68,700, and that of the monomer (2.5*S* particle) to be 34,700. Furthermore, Renaud *et al.*[5] reported a molecular weight of 60,000 for the constituent unit of microtubules isolated from cilia of *Tetrahymena*. Whether the value of about 60,000 is the molecular weight of the monomer or of the dimer of the microtubule protein has yet to be determined.

A comparison of amino-acid composition among structural proteins concerned with cell movement is illustrated in Fig. 1. The distances from the centre of the star to each angle on the outline correspond to the proportions of individual amino-acids. Sixteen amino-acids, excluding tryptophan and half cystine, are arranged from the top of each star clockwise according to the order shown in Table 1. It is clear that the amino-acid composition of the microtubule protein (5) is quite similar to that of invertebrate (insect flight muscle)

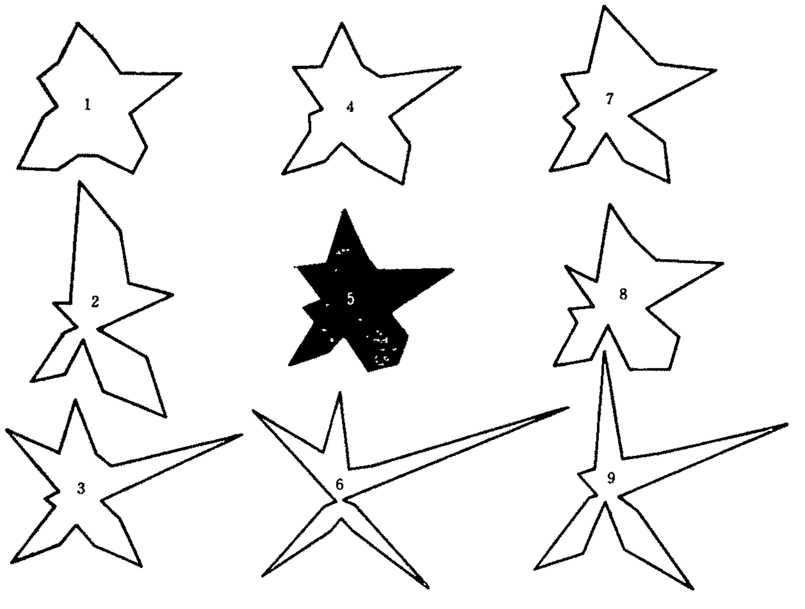

Fig. 1. Comparison of amino-acid composition among several structural proteins. 1, Rabbit actin[6]; 2, bacterial flagellin[7]; 3, rabbit myosin[6]; 4, insect actin[6]; 5, "tubulin"; 6, tropomyosin[6]; 7, acetic acid extract of *Tetrahymena* cilia[5]; 8, ethanol-insoluble fraction from 7[5]; 9, ethanol-soluble fraction from 7[5].

actin (4), except for a few amino-acids On the other hand, the composition is entirely different from that of flagellin which constitutes bacterial flagella (2), even though the microtubules of sperm flagella resemble bacterial flagella, as revealed under the electron microscope It is not strange that the acetic acid extracts of *Tetrahymena* cilia (7), especially its ethanol-insoluble fraction (8) (ref 8), have amino-acid compositions similar to that of the microtubule protein

Although the protein has other resemblances to actin, such as a super-precipitation-like phenomenon induced by ATP if combined with rabbit skeletal muscle myosin in low ionic strength[2], it differs from actin in the following ways The protein does not activate myosin ATPase in low ionic strength, nor is a viscosity drop observed after the addition of ATP to a mixture of myosin and the protein in high ionic strength[2] Furthermore, the protein contains guanosine tri and di-phosphate instead of adenosine tri and di-phosphate[9,10] The appearance of the microtubules is also different from that of actin filaments or thin filaments of muscle From these facts, we believe that the microtubule constituent is a different protein, for which we propose the name "tubulin"[11]

This work was supported by grants from the Ministry of Education and the Lalor Foundation I thank I Motoyama for carrying out amino-acid analyses

Nor$_2$Chlorpromazine Sulphoxide and 3,4-Dimethoxyphenethylamine

SEVERAL workers have found a spot isographic with 3,4-dimethoxyphenethylamine (DMPEA) in urine chromatograms of some schizophrenic patients but never or rarely in those of non-schizophrenic persons[1–3] A metabolite of chlorpromazine (CPZ), however, noted[4] to have been identified as nor$_2$chlorpromazine sulphoxide (N$_2$CPSO)[6], causes a spot close to or isographic with DMPEA in the chromatographic system originally used to detect the spots apparently diagnostic of schizophrenia[4,5] (referred to below as system 1) If a phenothiazine metabolite caused the apparently diagnostic spots (the pink spots) the following conditions must be fulfilled (1) The R_F for the metabolite in system 1 should be almost identical to that of DMPEA because fifteen pink spots were originally studied and even a small consistent difference in R_F between these spots and authentic DMPEA would have been detectable (2) The metabolite must be isographic with DMPEA in the two-way system used by Kuehl *et al* [2], for they reported that certain samples found positive by Friedhoff and van Winkle showed a ninhydrin positive spot isographic with DMPEA in their system (3) The metabolite must persist in urine after the parent drug has been stopped because all of the original patients and many of those found subsequently to have pink spots had been withdrawn from drugs for at least 2 weeks (4) The metabolite must give a pink spot with modified Ehrlich's reagent (DABA) following ninhydrin-pyridine and a negative reaction with DABA alone because this test was applied to the original spots[1] Also, an explanation must be found for the fact that material isolated from the original spots was indistinguishable from authentic DMPEA in several sensitive tests of identity[1,11] and for the fact that Takesada *et al* , who were aware of the problem of confounding drug metabolites and particularly N$_2$CPSO, found pink spots in the urine of schizophrenic patients and others as well[5]

(1) The spot caused by administration of CPZ is virtually isographic with DMPEA in system 1 Twenty-four hour urine samples were collected from five patients on CPZ (about 400 mg/day) Samples (500 ml) were extracted and chromatographed in butanol acetic acid water (4 1 1, system 1) according to the procedure of Friedhoff and Van Winkle[1] (omitting the BaCl$_2$ step) Three samples were also collected after substitution of other phenothiazines for CPZ (17 days being the maximum period off CPZ) Extracts equivalent to 20–50 ml of urine (on CPZ) and 150–250 ml (off CPZ) were chromatographed and spots located with ninhydrin[2] or ninhydrin-pyridine[1] Duplicate strips were sprayed with sulphuric acid 50 per cent v/v ethanol 4 1, which turns most non-phenolic CPZ metabolites pink In each case on CPZ dense spots were found which were purple with ninhydrin and pink with 50 per cent sulphuric acid Mean difference in R_F between these spots and DMPEA was 0 01 (3 patients, 10 pairs of spots on CPZ, 4 pairs off CPZ) (2) A sample of 15 μg of DMPEA enlarged or intensified the spot in the system of Kuehl *et al* [2] Also authentic N$_2$CPSO and DMPEA were found to be inseparable in this system (spotting a mixture of 10 μg each) (3) A ninhydrin positive spot isographic with DMPEA in system 1 was found in all specimens obtained after CPZ had been stopped, but the significance of this finding is limited by the fact that other phenothiazines had been substituted for CPZ It was possible to overcome this limitation, however, because a metabolite of CPZ isographic with DMPEA in chromatographic systems other than system 1 had been reported to persist in urine for up to 25 days after the withdrawal of CPZ[6,7] (in the absence of substitute medication) and we were able to show that this metabolite was N$_2$CPSO (15 μg of DMPEA or N$_2$CPSO mixed with the unknown enlarges or intensifies the spot in both of the other two-way systems and DMPEA and N$_2$CPSO spotted as a mixture of 10 μg each are also not separated) There is an unusual chromatographic similarity between DMPEA and N$_2$CPSO because the three two-way thin-layer systems in which we have found them inseparable easily resolve closely related metabolites of CPZ Our studies strongly support the previous identification of the CPZ metabolite isographic with DMPEA in system 1 as N$_2$CPSO because an eluate of the spot produced a streak isographic with N$_2$CPSO in a second

chromatographic system (isopropanol 30 per cent ammonia water 20 1 2—system 2) and an eluate of this twice chromatographed material (unsprayed) gave an ultraviolet spectrum perfectly characteristic of N_2CPSO Also we recover at least 50 per cent of added N_2CPSO which normally accounts for 2 4–5 0 per cent of an administered dose of CPZ[8–10] and there is no other spot on our chromatograms of sufficient density to be N_2CPSO A slight discrepancy between the unknown spot and authentic N_2CPSO in system 1 was reduced if authentic N_2CPSO was added to an extract before chromatography or if the unknown was eluted and re-chromatographed in system 1 We can therefore conclude that the spot studied by us is N_2CPSO and that it persists in urine for at least 25 days after the withdrawal of CPZ (4) In concentrations greater than 5 µg, N_2CPSO gives a pink spot with DABA alone in contrast to DMPEA With 2 5 µg on a spot, however, authentic N_2CPSO gives only a very faint reaction with DABA alone, and if the spot is developed in system 1 before dipping in DABA the reaction with DABA is negative The purple colour with ninhydrin-pyridine, however, is definite with 2 5 µg both on an undeveloped spot or after development in system 1, and the spot turns pink with subsequent treatment with DABA

N_2CPSO, however, is not the material isolated by Friedhoff and Van Winkle Their unknown was indistinguishable from DMPEA in the two systems used by them to study eluates of the spots[1] whereas N_2CPSO streaks in these systems and clearly separates from DMPEA in one of them (system 2) Also the ultraviolet absorption spectrum for N_2CPSO carried through the extraction and chromatography has maxima at 240, 276, 300 and 343 whereas the unknown of Friedhoff and Van Winkle had maxima only at 234 and 279 (ref 1) (maxima for DMPEA were found by us to be 232 and 280) and the melting point of the unknown material of Friedhoff and Van Winkle is 152–154° C[11] (virtually identical to DMPEA) while that of N_2CPSO HCl is 300° C Finally, DMPEA has been identified in human urine by mass spectrometry[12] and the acid metabolite of DMPEA, 3,4-dimethoxyphenylacetic acid (DMPAA), has also been found in human urine using specific methods[7,13] It is therefore likely that DMPEA was present on the spot and isolated by Friedhoff and Van Winkle There is, however, considerable evidence suggesting that DMPEA may not cause a visible pink spot diagnostic of schizophrenia (*a*) Those workers other than Friedhoff and Van Winkle who have found what they thought was DMPEA[2,7,14] have not found it in amounts capable of causing a definitely detectable spot in system 1 (spotting a 100 mg creatinine equivalent as did Friedhoff and Van Winkle) (*b*) DMPAA has been found in equal amounts in schizophrenic and non-schizophrenic persons[7,13] (*c*) Those workers who have studied patients never treated with drugs[15] or who have been aware of confounding spots caused by phenothiazine metabolites[6,16–18] have either not found apparently diagnostic spots or have found the characteristic spots only in very low frequency in schizophrenic urine and have shown them not to be preponderantly DMPEA Our findings and all of those cited are consistent, however, with the possibility that N_2CPSO or a phenothiazine metabolite with similar properties caused spots apparently diagnostic of schizophrenia, but that DMPEA was present on the spot as well in low amounts and was isolated by Friedhoff and Van Winkle, leading them to believe that the apparently diagnostic spots were DMPEA If this occurred, it is not clear why N_2CPSO did not appear in the systems used to study eluates of the original spots N_2CPSO streaks in these systems, however, and if present in low concentrations originally might not have produced a visible spot or if eluates were combined might have caused a streak which looked like "background" The postulated trace amounts of DMPEA may have become more visible in the secondary systems in the absence of other constituents of the extract, or eluates may have been combined, possibly accounting for the presence of visible spots in the secondary systems but not in the chromatograms of non-schizophrenic persons This, of course, is speculation and the circumstantial evidence adduced here does not definitely exclude the possibility that schizophrenic patients excrete DMPEA in greater amounts than normals

Takesada *et al*[5] assumed that the spot which they found to be isographic with DMPEA (rather than N_2CPSO which was nearby) and which they found in a high percentage of normals was the one studied by Friedhoff and Van Winkle But subsequently it was confirmed that the pink spot never, or only rarely, occurred in the urine of non-schizophrenic persons[2,3] and it was shown that the substance studied by Takesada *et al* is only poorly extracted using the methods of Friedhoff and Van Winkle and is not DMPEA[6] It disappears with dietary restriction and may not be more prevalent in the urine of schizophrenic patients than others[19]

We thank Dr F Snyder, Dr H Meltzer, Dr P Cardon and Dr E Hanson for the urine samples and Dr A Manian for the authentic nor₂chlorpromazine sulphoxide Dr J Durell gave valuable suggestions

Effects of Very Large Doses of Penicillin G given Orally to Rats

Nimni and Bavetta[1] reported a connective tissue disorder in rats fed penicillamine The disorder was reflected by decreased breaking strength of unwounded and wounded skin, decreased collagen synthesis in polyvinyl sponge implants and a diminished proportion of insoluble to soluble collagen in such granulomas We have studied this phenomenon in rats and guinea-pigs[2–4] and have likened it to the lathyritic state induced by feeding β-amino propionitrile, a view also expressed by Nimni[5] Penicillamine can be derived[6] from both the *in vitro* and the *in vivo* hydrolysis of penicillin, so we set out to determine whether the feeding of very large doses of penicillin would cause a collagen defect similar to that caused by penicillamine

Twenty-two Cobbs rats weighing 120–150 g were fed freely on a diet of commercial chow for 10 days, paired and assigned to one of two groups The rats were anaesthetized with pentobarbital and standard paravertebral skin incisions were made and polyvinyl alcohol sponges implanted subcutaneously. The wounds were sutured and the animals were then fed freely on experimental diets. One group received ground chow supplemented with 25 mg of pyridoxine, the other received a similar diet which also contained 50 g of potassium penicillin *G*/kg of dry food. After 2 weeks the rats were killed, clipped and their pelts removed. Each pelt was cut into seven single strips 0.5 cm wide with a multi-blade cutting device[7]. Adjacent strips were measured for breaking strengths immediately or after immersion in 10 per cent buffered formalin[8]. Unwounded ventral abdominal skin was cut into a single strip and its breaking strength measured immediately[7]. Student's *t* test for paired samples was used to calculate the statistical significance of the data.

The unwounded skin of the animals treated with penicillin was weaker breaking strength 1,289±149 g as opposed to 1,600±146 g for the controls ($P<0.1$). The mean breaking strength of the wounds of rats treated with penicillin was 478±40.2 g, however, compared with 603±43 g for the controls, this 21 per cent decrease in breaking strength was significant at the 0.001 level. Fixation of the wounds in formalin resulted in mean breaking strengths of 2,225 g for both groups.

Penicillin produced alterations in the intestinal flora (unpublished results from this laboratory) and it occurred to us that the effects of penicillin on wound strength might be reflexions of the altered bacteriological status. Accordingly, an experiment was conducted using twenty-two Fischer germ-free rats. The conditions were similar to those in the previous experiment with several exceptions (1) the animals were pair fed, (2) whereas the intake of potassium between groups was not controlled in the first experiment, it was regulated in the second experiment by supplemental administration of potassium acetate, bicarbonate and citrate to the group not receiving potassium penicillin *G*, (3) the animals were killed 3 weeks after wounding. The wounds of the animals treated with penicillin were again substantially weaker than the controls (breaking strength 1,508±63 g as opposed to 2,196±111 g, $P<0.001$) as was the unwounded abdominal skin (2,672±174 g as opposed to 3,120±127, $P<0.05$). Fixation in formalin resulted in breaking strengths of 3,892±206 and 4,381±227 ($P<0.2$).

The experiment with germ-free rats implies that the decreased wound strength of rats treated with penicillin is not dependent on the changes in microbial flora.

In both experiments, the oral administration of potassium penicillin *G* resulted in a significant decrease (21 per cent and 30 per cent) in the breaking strength of wounds in rat skin tested immediately after killing. After immersion of adjacent wound strips in 10 per cent formalin, the breaking strength of the wounds was similar in both groups. The tanning effect of formaldehyde on collagenous proteins was described by Gustavson[9] and its effect on the breaking strength of wounds was reported by Levenson *et al.*[8] The "correction" by formaldehyde of the decreased breaking strength of the wound of the rats treated with penicillin is evidence that the total amount of collagen present in the wounds of both groups is similar and that the defect is qualitative rather than quantitative—namely, decreased crosslinking of collagen. This is supported by the similar quantities of collagen (hydroxyproline) in the sponge granulomas of both penicillin treated and control animals, and, as will be reported elsewhere, the similar histological appearances of the wounds and sponge granulomas in both groups.

We think that the collagen maturation defect resulting from orally administered potassium penicillin *G* is mediated through one or more of its naturally occurring metabolites, such as penicillamine. Schwartz and Buckwalter[10] and Dennen and Davis[11] have shown that in conditions of *p*H and temperature close to physiological conditions, penicillin undergoes significant degradation even in the absence of enzymes. From the point of view of the stay of ingested penicillin in the acidic environment of the stomach of rats and the mildly alkaline milieu of the remainder of the intestinal tract, appreciable breakdown of benzyl penicillin to benzyl penicilloic acid (cleavage of the lactam), penicillic acid, penicillenic acid, penaldic acid and some penicillamine would be expected.

It is possible that some of these compounds inhibit the crosslinking of collagen because they interact with the active sites (aldehydes) of collagen which are usually involved in crosslinking. Another possible explanation involves the interaction of penicillin degradation products with copper. Penicilloic acids react with heavy metals to yield mercaptides, penicillamine chelates, and phenacetylaminomalonaldehyde. Thus copper would be sequestered in such a reaction. Copper could also be sequestered by the other breakdown products of penicillin catabolism, where copper itself is not contributing to the hydrolysis. It is known that copper deficiency leads to connective tissue disorders related to lathyrism[12] and that the lathyrism induced by β-amino propionitrile can be antagonized by increased copper supplementation[13].

Extremely high doses of penicillin *G* were used in these experiments. These doses are far greater on a relative basis than those used clinically, even for the treatment of patients with certain life-threatening infections. Our data should not be construed as indicating that penicillin as used for the treatment of patients interferes with their collagen metabolism.

Epidermal Iron Pigments in Red Species

FROM the hair of red mongrel dogs and New Zealand red rabbits we have extracted iron pigments which in most respects are similar to the pigments isolated before from red human hair (trichosiderin)[1-3] and Rhode Island Red chicken feathers (feather siderin)[3,4]. These findings suggest that iron compounds play a central part in certain types of red pigmentation. To facilitate studies in other species, a general description of these pigments is presented.

The amounts of extractable pigment depend on the compactness of the horny material, so it is advisable to use at least 4–5 g of hair for extraction. When boiled with 0.1 N HCl, loose rabbit fur and chicken feathers yield a deep red-brown solution within 10 min. The compact human and canine hair requires boiling at least for 1 h in acid to give pale pink to brown–yellow solutions. From rabbit fur and chicken feathers the pigments can also be obtained in mild conditions (weak acids or alkalis at 40° C) as orange-coloured protopigments[4].

The pigments extracted with boiling acids have the following characteristics: at *p*Hs greater than 2 the red extracts turn yellow and can reverse to red; in other words, they behave like indicators. The pigment is precipitated at *p*H 7. From the supernate at *p*H 4·3 another small fraction frequently precipitates on standing. This fraction contains relatively large amounts of the iron-chromophore responsible for the indicator properties of the siderins.

When redissolved in 0·1 N HCl, the pigment can be split with KSCN (2 per cent final concentration) to brown protein which either yields traces of or no iron, and a red supernate which is rich in iron. The latter retains the indicator properties of the original extract, but is dialysable. When the pigment precipitated from this supernate at *p*H 7 is dissolved in 0·1 N NaOH and passed through a column of 'Sephadex *G*-25' it separates into two bands: a more rapidly moving brown protein and an orange-pink chromophore. By precipitation at *p*H 4·3, and repeated passage through 'Sephadex *G*-25', the chromophore can be further purified until it contains no protein.

In man, rabbit and chicken—the species studied so far—the purified chromophore contains 1·4–1·7 per cent iron in the ferric form, very firmly bound to the molecule. The two chromophores analysed (human and rabbit) contain sulphur[2]. The chromophores are stable at all *p*Hs. Their absorption bands in acid solution (maximum about 535 mμ) become less pronounced and shift to shorter wavelengths on alkalinization. The characteristic vivid purple colour in acids, changing reversibly to orange when alkalinized, permits detection in concentrations up to 10^{-6}.

To these pigments the following general structure can be assigned: (chromophore-Fe^{III}) . . . protein. In the siderins the protein part accounts for about 98 per cent of the molecule.

The iron pigments are the principal pigments in red human hair, rabbit fur and chicken feathers. The limited yield of trichosiderin from compact horny structures is caused by gradual destruction during boiling with acids[3,4]. On prolonged extraction, rabbit fur and chicken feathers turn dark grey.

The consistent presence of these unique substances in some red species suggests synthetic pathways involving iron which differ from the classical black melanogenesis. Our findings do not support the theory implicating tyrosinase in the synthesis of human red hair pigments[5]. The alleged role of tyrosinase in this process is based essentially on two observations: the DOPA-positivity, and the purported tyrosinase activity of red melanocytes in the hair matrix; the latter is derived from autoradiographic evidence. The DOPA-positivity can be accounted for by a non-specific catalytic action of the iron pigment on the autoxidation of DOPA[1,6]; ferric ions have a similar effect. The autoradiographic findings obtained with labelled tyrosine could be caused by incorporation of this amino-acid into the protein part of the iron pigment without any further oxidation.

The discovery of a new pigmentary system of phylogenetic antiquity has implications for anthropology, genetics and biochemical studies of nonhaem iron proteins to which these pigments belong. The mild methods with which the protein may be split off from the chromophore could be useful for obtaining the protein part of a melanoprotein and for studying its mode of attachment to the pigmented portion. In preliminary analyses various protein fractions had a remarkably similar amino-acid composition within the same species.

These iron pigments isolated from red hair and feathers of four species are probably widespread in nature and are unlike any known to us.

I thank Dr Miklos Bodanszky for amino-acid analyses and for constant advice. This work was supported in part by the National Institutes of Health, US Public Health Service.

IMMUNOLOGY

Relation between Rat Slow Alpha$_2$-globulin and Alpha$_2$-macroglobulin of Other Mammals

SLOW alpha$_2$-globulin[1] (SA_2G) of the rat is a peculiar serum protein in that it is absent from the serum of the normal, non-pregnant adult rat[1-4] but appears in a number of conditions, including the foetal and neonatal states[3-5], during pregnancy[2-6], during neoplastic growth[2-4,6-9], after interference with the kidney[10,11] and other conditions[12]. On the other hand, alpha$_2$-macroglobulin[13] (A_2MG) is a protein found in the sera of normal, non-pregnant humans[14-16] and other mammals[17-21] but not in the mouse (ref. 22 and my unpublished work). There are indications in the literature that the two materials may be similar despite the divergent situation in the adult.

The concentration of human A_2MG is increased above the normal adult state in at least four situations similar to some of those in which SA_2G appears in the rat: pregnancy[23-25], youth[16,25,26], during neoplastic growth[15,28] and in the nephrotic syndrome[15]. The molecular weights of porcine and human A_2MG are given as 960,000 and 900,000, respectively[21,28], and I calculate the molecular weight of rat SA_2G to be 900,000 to 1,000,000 on the basis of gel exclusion chromatography on 'Bio-Gel *A*15*m*' (BioRad Laboratories, Richmond, California).

In view of these indications of similarity, I have investigated whether or not the two materials are also similar when examined by starch gel electrophoresis, immunodiffusion and immunoelectrophoresis. Rats used, general procedures and vertical starch gel electrophoresis have already been described[4]. SA_2G was caused to appear in the rats, that is, the rats were made positive, by the administration of the lipopolysaccharide (endotoxin) of *Salmonella abortus equi*[29]. Human sera were obtained from four healthy, non-pregnant adults of both sexes or in lyophilized form (Pentex Incorporated, Kankakee, Illinois). For the purpose of this work, no appreciable differences were noted among the sera from the various sources. Other animal sera were also obtained in lyophilized form from Pentex. Antiserum to human A_2MG, produced in rabbits, was that of the Behringwerke, Marburg-Lahn, Germany (Hoechst Pharmaceuticals, Inc., Kansas City, Missouri). Antisera to rat SA_2G were prepared in rabbits by the injection of an impure preparation of SA_2G and complete Freund's adjuvant. The antisera obtained were absorbed to completion with sera from normal, that is, SA_2G negative, rats. The double immunodiffusion method of Ouchterlony[30] was carried out either in Petri dishes of 45 mm diameter or on microscope slides using 1 per cent agar with 1 per cent sodium chloride and 0·1 per cent sodium azide. The gels were examined in a dark-field arrangement and, in some cases, also after drying and staining. Immunoelectrophoresis was carried out with, and according to the instructions for, the model 6800 *A* of the LKB-Produkter AB (Stockholm, Sweden).

Fig. 1 gives representative examples of the results obtained. On the starch gel electrophoresis plate (Fig. 1*a*), sera from man, rabbit, cow and horse all show a band coincident in position with that of SA_2G in the serum of the positive rat, a position that is empty, of course, in the pattern of the serum from the negative rat. These results are in accord with a similar finding by Jacquot-Armand and Guinand[21] concerning human serum. In view of the close phylogenetic relationship between the Rodentia and the Lagomorpha, it is interesting to note that this band is consistently weaker in patterns of rabbit sera than in those from other, non-rodent, mammals.

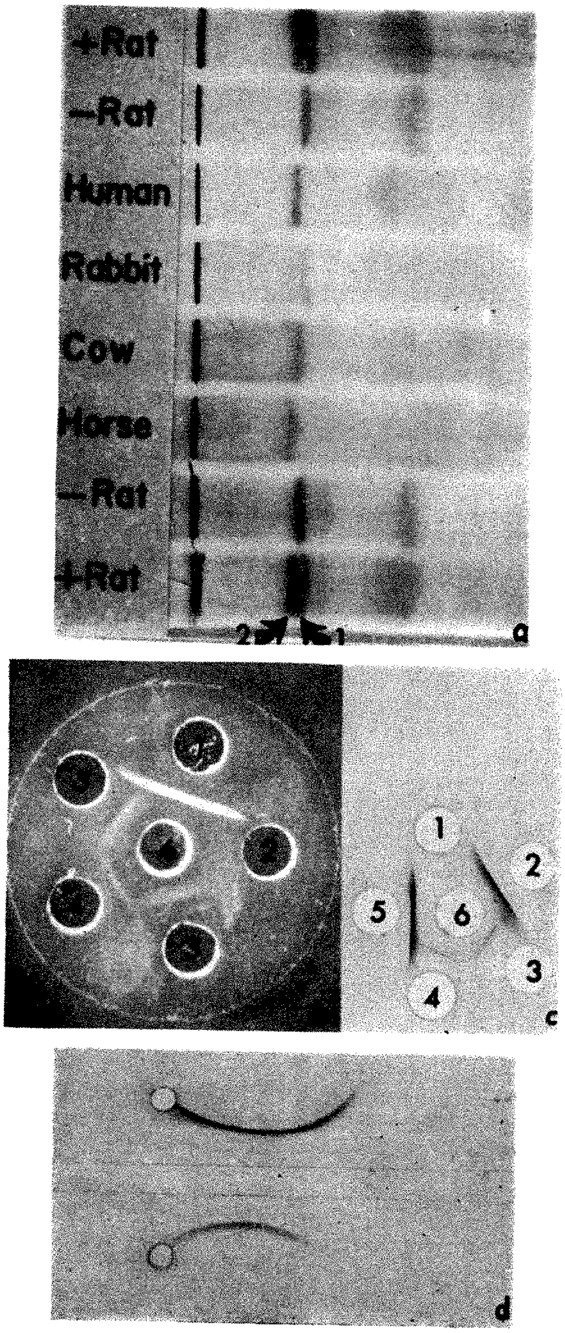

Fig. 1. *a*, Cathodal portion of vertical starch gel electrophoresis plate. Starting wells immediately to the right of the label; migration from left to right. Arrow 1, slow $alpha_1$-globulin; arrow 2, slow $alpha_2$-globulin. *b*, Dark field view of double diffusion plate. Well 1, rat serum containing slow $alpha_2$-globulin; well 2, rat serum not containing slow $alpha_2$-globulin; well 3, bovine serum; well 4, canine serum; well 5, human serum; well 6, antiserum against an impure preparation of rat slow $alpha_2$-globulin absorbed to completion with normal rat serum. *c*, Dried and stained double diffusion plate. Well 1, rat serum not containing slow $alpha_2$-globulin; well 2, human serum; well 3, impure preparation of rat slow $alpha_2$-globulin; well 4, rat serum containing slow $alpha_2$-globulin; well 5, human serum; well 6, antiserum to human $alpha_2$-macroglobulin produced in rabbits. *d*, Dried and stained immunoelectrophoresis plate. Migration from left to right. Top well, human serum; bottom well, rat serum containing slow $alpha_2$-globulin; centre trough, antiserum to human $alpha_2$-macroglobulin produced in rabbits.

Fig. 1*b* demonstrates, first, the specificity of the absorbed antiserum for rat SA_2G in that it will still react with rat serum containing SA_2G but will not do so with serum from a normal, SA_2G negative rat. Second, there is shown the cross-reaction of this specific antiserum with a component in normal human, bovine and canine sera. The spurs formed indicate that the various sera do not contain an immunologically identical but only similar material. This finding is in accordance with similar findings on the A_2MG of other mammals[17,20]. The sera of these three mammals therefore contain a material which is immunologically very similar to rat SA_2G.

These conclusions are supported by the type of result, shown in Fig. 1*c*, obtained when the antiserum in the centre well is commercial anti-human A_2MG. A definite reaction is obtained between this material and the positive rat serum in well 4 while there is no reaction with negative rat serum (well 1). This again demonstrates the specificity of the reaction. That rat SA_2G is immunologically only similar to human A_2MG is again shown by the spur formation at the intersection of the reaction lines with positive rat serum (well 4) and with human serum (wells 2 and 5). An impure preparation of rat SA_2G, used as the injection antigen for the production of the antisera used in Fig. 1*b*, was placed in well 3 and reacted like positive rat serum.

In immunoelectrophoresis also (Fig. 1*d*) positive rat serum and human serum, reacted against commercial anti-human A_2MG, show similar reaction arcs in similar locations.

I conclude from the data in the literature and the experimental evidence described that: (*a*) the SA_2G of the rat is chemically, immunologically and probably functionally similar to the A_2MG of other, non-rodent, mammals and (*b*) the rat, and possibly other rodents, differ from most mammals in that the normal range of concentration of this material in the serum includes or comes very close to zero.

Differences in Localization of *Salmonella* Flagella in Lymph Node Follicles of Germ-free and Conventional Rats

STUDIES on the induction of antibody production have shown that subcutaneously injected immunogens can be processed in two ways by draining lymph nodes[1]. Most of the immunogen retained in the node is actively phagocytosed by the macrophages of the sinuses of the medulla, while a smaller portion becomes attached to the surfaces of dendritic cellular processes in the primary follicles of the cortex[1–5]. This latter phenomenon seems to be important because germinal centres subsequently form in immediate relation to this surface-retained immunogen[1–5]. Because the ability of follicular cells to capture immunogens is decreased in tolerant animals and increased in actively or passively immunized animals[6–8], it may be that opsonins, specific or non-specific, are required for follicular localization of immunogens and thus for the formation of germinal centres in lymph nodes. To test this hypothesis further we have compared the degree of follicular localization of flagella of *Salmonella adelaide* labelled with iodine-125 in germ-free rats and in conventionally raised rats, assuming that germ-free rats would have experienced less exposure to antigens which might have induced cross-reacting or non-specific opsonins.

Germ-free and conventional female Sprague–Dawley rats weighing 75–115 g were used. On arrival, the germ-free rats were transferred into a peracetic acid-sterilized flexible plastic isolator (Labco, Columbus, Ohio) by conventional sterile techniques. Two were kept in each cage. Purina 5010*C* laboratory chow, water, bedding and the necessary glassware and instruments were introduced into the isolator after sterilization in an autoclave. Bedding from the isolator was changed, removed and cultured for bacteria twice weekly. At the time of injection of ^{125}I labelled flagella, two bacteria were found contaminating the isolator, *Clostridium perfringens* and *Cl. capriocum* (identified by the Communicable Disease Center, Atlanta, Georgia). In the experiment testing the immunogenicity of flagella in germ-free rats, *Cl. perfringens* and *Cl. multifermentans* became contaminants 2 weeks after primary immunization. No other bacteria were ever cultured from the bedding, isolator or rats. Conventional rats injected subcutaneously four times at 2 day intervals with $1–1\cdot5 \times 10^8$ organisms of each of these *Clostridium* species killed with formalin did not develop detectable immobilizing antibody to *Salmonella adelaide*.

Flagella from *Salmonella adelaide* were prepared and iodinated with iodine-125 (New England Nuclear Corp., Boston, Mass., lot. No. 2–674) by the chloramine-*T* method described earlier[9]. The radioactive antigen was injected in doses of 0·8 μg of flagella in 0·1 ml./hind foot pad into groups of ten germ-free and ten conventional rats under pentobarbitol anaesthesia. Pentobarbitol solutions and flagella suspensions were sealed in glass ampoules which were exposed for 1 h to a 10 per cent peracetic acid spray before being put in the isolator. Suspensions of flagella injected into the conventional rats were handled in the same way as those injected into the germ-free rats except that they were kept at room temperature for a time equivalent to that required for ampoules to pass into the isolator. One conventional rat died 25 min after injection of antigen and one germ-free rat was killed after 60 min. Two rats from each group were killed at intervals of 4 h and 1 and 7 days after injection of antigen, and single rats were killed after intervals of 8 h and 2 and 3 days. Both popliteal lymph nodes, a para-aortic lymph node and the spleen were removed from each rat, fixed in 10 per cent formol-saline for 24 h, transferred to 70 per cent ethanol, and counted individually on a Packard 'Auto-Gamma' scintillation counter simultaneously with diluted samples of serum from each animal and with a diluted sample of the injected radioactive suspension of flagella. Subsequently, autoradiographs of 5μ sections of the organs were prepared using Kodak *NTB*3 emulsion diluted 1 : 1 with distilled water, and methyl green-pyronin stain.

At times later than 24 h after the injection of labelled flagella the levels of radioactivity in the popliteal nodes and in the spleen, but not in the serum, were slightly lower in the "germ-free" rats than in the conventional rats. After exposure for 33 days, autoradiographs of the popliteal nodes from germ-free and conventional rats had distinctly different patterns of concentration of label in follicular cells (Figs. 1 and 2.) In popliteal nodes from conventional rats, label appeared in follicles within 4 h of injection, was heavily concentrated in follicles by 8 h and persisted here until 7 days after injection. In the germ-free rats, however, no label was found over follicles at 4 h

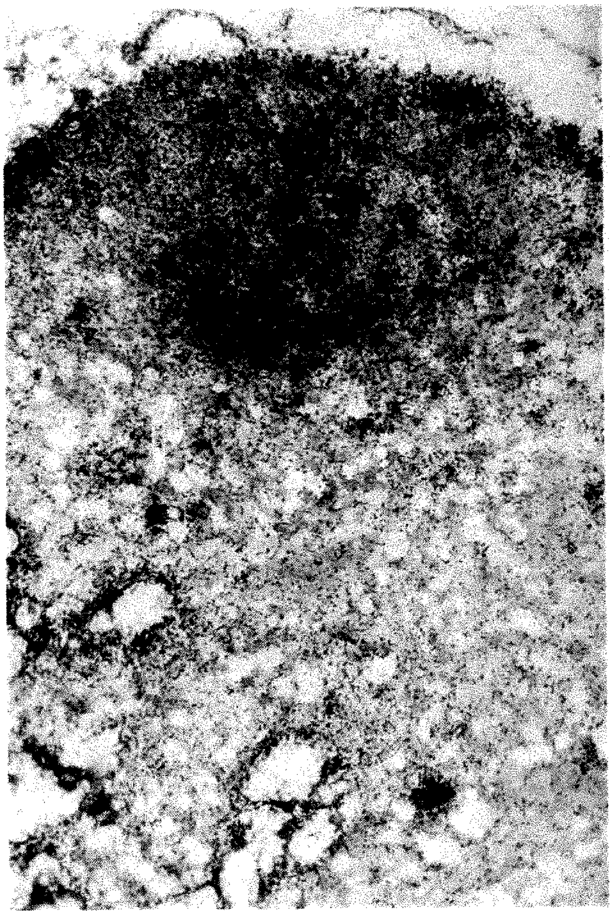

Fig. 1. Photomicrograph of an autoradiograph exposed for 33 days, showing a section of a popliteal node from a conventional rat 8 h after injection of flagella labelled with iodine-125. Labelling is present over the phagocytic cells of the peripheral and medullary sinuses and is concentrated over a primary cortical follicle. Methyl green-pyronin stain, × 60.

Table 1. COMPARISON OF THE CONCENTRATION OF LABELLED FLAGELLA IN THE PRIMARY FOLLICLES OF THE POPLITEAL LYMPH NODES IN THE GERM-FREE AND CONVENTIONAL RATS 24 h AFTER INJECTION

Rats	Nodes examined	Proportion of follicles counted with grains	Statistic	Size of follicular cross-section (μ^2)	Individual* follicular concentration of grains	Grains/follicular cross-section
Conventional	4	14/17	Mean	26,590	147	9,401
			Median	20,800	117	2,995
			Range	(11,200–52,800)	(0–385)	(0–36,960)
Germ-free	4	12/13	Mean	20,280	47	2,660
			Median	17,600	34	979
			Range	(4,480–37,600)	(0–166)	(0–9,030)

* Follicular concentration = grains/500μ^2 in follicle – grains/500μ^2 in adjacent cortex.

and only a trace amount was seen by 8 h. At 24 h and thereafter there was always some label over the follicles, but the concentration of this label was less than that in nodes from comparable conventional rats. In contrast, within 4 h of injection of radioactive flagella equally heavy labelling was found over the medullary areas of the popliteal nodes from both groups of rats.

The difference in degree of concentration of antigen in follicles in the popliteal nodes of the "germ-free" rats compared with those of the conventional rats was more accurately established by grain counting[10]. Autoradiographs (exposed for 10 days) of popliteal nodes of all rats killed 24 h after antigen injection were examined. Follicles containing germinal centres were not counted. The concentration in the follicles was expressed as the excess of this concentration over the concentration in the diffuse cortex, the latter being determined individually for each node. These data are shown in Table 1. The range of values, mean values, and median values of the concentration of labelled flagella in follicles and of grains/cross-section of follicles are all smaller in the germ-free rats than in the conventional rats. The sizes of cross-sections of follicles were comparable. There was little difference in the proportion of follicles which retained antigen between the two groups.

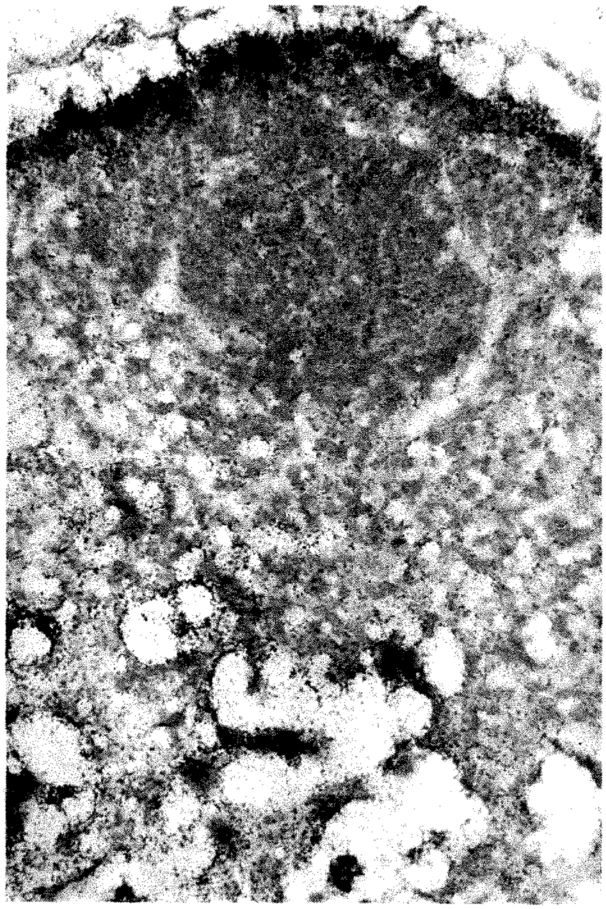

Fig. 2. Photomicrograph of an autoradiograph exposed for 33 days showing a section of a popliteal node from a germ-free rat 8 h after injection of flagella labelled with iodine-125. Although the phagocytic cells of the sinuses are as heavily labelled as those in the node from the conventional rat (Fig. 1), the primary cortical follicle, in contrast, has only a small increase in concentration of labelling compared with the diffuse cortex. Methyl green-pyronin stain, × 60.

Neither consistent germinal centre formation nor plasmacytopoiesis occurred in the popliteal lymph nodes from the conventional or the germ-free rats in response to these doses of iodinated flagella. To establish the immunogenicity of the particular flagella preparation used, and to determine the immunogenicity of flagella in germ-free rats, new groups of conventional and germ-free rats were injected with non-iodinated but otherwise similarly handled flagella of the same batch in doses of 0·05 μg or 0·5 μg per hind foot pad. The rats were bled 42 days later and given secondary injections of 5·0 μg flagella/hind foot pad. The rats were bled again 7 and 14 days after the secondary injections. The titres of *Salmonella adelaide* immobilizing antibody[11] in the germ-free rats were higher than those in the conventional rats after both primary doses and secondary stimulation (Table 2), although not as high as expected on the basis of past experience with another strain of rats[12].

Table 2. AVERAGE TITRES OF IMMOBILIZING ANTIBODY IN GERM-FREE AND CONVENTIONAL RATS

	Primary	Secondary	Average log^2 titre (1 = 1/5 dilution)* 42 day primary	7 day secondary	14 day secondary
Germ-free	0·05 μg	5·0 μg	7·3	11·4	13·8
	0·5 μg	5·0 μg	9·2	12·5	14·0
Conventional	0·05 μg	5·0 μg	0·6	9·5	9·8
	0·5 μg	5·0 μg	5·4	11·8	12·2

* Six rats in each group. At the beginning of the experiment, germ-free rats were estimated to weigh an average of 100 g and conventional rats weighed an average of 75 g.

In conclusion, localization of *Salmonella* flagella in the lymphoid follicles but not in the medullary macrophages of rat lymph nodes is less efficient in rats raised in a germ-free environment than in conventionally raised rats. This is consistent with the hypothesis that localization of immunogens in follicles, and thus germinal centre formation, is dependent on the pre-existence of antibody. The fact that the germ-free rats of this experiment had the ability to retain some flagella in the follicles may have been caused by antibodies which were not highly specific, or to slight previous stimulation with specific antigens present in the food, the probable source of the *Clostridium* spores causing contamination of the isolator. Alternatively, the localization of the antigen in the follicles, obviously delayed in the germ-free rats, may have been caused by *de novo* antibody synthesis to the injected antigen. The dissociation of the degree of concentration of flagella in follicles and the antibody titres produced in the germ-free rats compared with the conventional rats might indicate that the surface-retained immunogen of lymph node follicles has little to do with the initiation of antibody production *per se*. Careful study of possible early differences in anti-flagella antibody production in germ-free and conventional animals would, however, be necessary to make this more certain.

BIOLOGY

Nutritional Evaluation of Bacterial Diets in Growing Rats

There has recently been interest in the potential of bacteria (single cell protein) as a food for populations on a diet deficient in protein[1,2] and for astronauts on long space flights There seems to be no literature on the growth of animals fed for extended periods on bacteria as the only nitrogen source or as a large proportion of the diet This communication reports the results obtained when weanling rats were fed on diets containing acetone-killed *Escherichia coli B* or *Hydrogenomonas eutropha* as a minimal nitrogen source, and of feeding diets which utilize these bacteria as the chief source of calories The findings are useful in establishing the extent to which bacterial protein can replace conventional protein and the degree to which a diet containing large amounts of whole bacteria is compatible with good nutrition and health *H eutropha* is of particular interest because it is under consideration as a possible source of regenerated food for use on long space flights[3]

The concept that bacterial protein may be a useful nutritional supplement is not new It has been shown[4,5] that the addition of 5 per cent by weight of purified *E coli* protein to a diet containing only sufficient protein for minimal growth produced the same or better stimulation of growth in weanling rats as that produced by 5 per cent fishmeal protein Animals fed on whole cells killed by heat responded as well as those fed on purified protein

There have been studies of the nitrogen balance of bacteria over a short period The protein of mixed rumen bacteria killed with ethanol has a biological value of 81 per cent and a digestibility of 74 per cent[6,7] in rats

It has also been shown[8] that the protein of live *E coli* cells has a biological value of 69 per cent and a digestibility of 81 per cent These values were not changed noticeably after freeze drying the cells, sonically disrupting the dried cells or altering the growth medium The biological value for *Lactobacillus arabinosis* was found to be 52 per cent with a digestibility of 84 per cent

There are two potential problems related to growth over a long period on diets containing *H eutropha* First, the bacterial protein in whole cells may not be available for digestion or, if digested, the distribution of amino-acids may not be compatible with good nutrition A relatively good indicator of protein value is the "Essential Amino Acid Index"[9] When this index is calculated for casein, *Pseudomonas* (*Hydrogenomonas*) *saccharophilia*[10] and *H eutropha*[11], values of 88, 75 and 78, respectively, are obtained Thus *H eutropha* protein should have a biological value somewhat lower than casein but still be of relatively high quality

The second problem which might arise relates to the amount of urine which must be excreted to eliminate compounds containing nitrogen from the body The limited ability of the kidney to concentrate urea and uric acid indicates that when large amounts of protein are eaten, more water must be ingested It must therefore be shown whether the increased volumes associated with diets containing these bacteria as the chief calorie source will be too large to preclude their use in this manner It is significant that good nutritional practice avoids diets containing more than 45 to 50 per cent protein because of this and associated problems[12]

There were difficulties in obtaining an adequate amount of *H eutropha* A preliminary study was therefore done with a single lot of *E coli B* grown out to 3/4 log phase on phosphate-buffered minimal medium, washed successively with saline and acetone and then air dried The resultant dried powder contained no viable *E coli* and contained 78 per cent protein (N × 6 25) These dried cells were incorporated at levels of 10 7 and 71 8 per cent by weight into diets containing 10 per cent corn oil, 4 per cent of the Wesson modification of Osborn and Mendel's salt mixture, vitamins, and the remainder potato starch. Similar control diets were prepared containing 8 0 and 66 0 per cent casein An equal weight of water was blended into the 8 per cent casein and 10 7 per cent *E. coli* diets to give a paste Twice this amount of water had to be added to the 66 per cent casein and 71 8 per cent bacteria diets to give pastes of the same consistency The nitrogen content on a dry basis of these diets as determined by analysis was 1 74 per cent for the low protein diets and 9 04 per cent for the high protein diets This is equivalent (N × 6 25) to 7 75 and 57 0 per cent protein The true protein content of the bacteria containing diets, however, is probably reduced by 8 to 10 per cent of the stated value because of the presence of nucleic acids All diets were stored at 4° C and fed fresh to the rats daily for 14 days The male Sprague–Dawley rats (66 ± 3 g) were caged as pairs, food and water consumption was recorded daily

Table 1 RESPONSE OF MALE WEANLING SPRAGUE–DAWLEY RATS TO DIET CONTAINING ACETONE-KILLED BACTERIA

Material	Per cent	No of animals	Total per animal during experimental period ± S E M Weight gain (g)	Food (g)	Water (g)	Urine (ml)	Faeces (g)
			14 day study with *E coli*				
Casein	8 0	8	33 ± 5	214 ± 14	432 ± 35		
Casein	66 0	6	42 ± 1	138 ± 3	460 ± 27		
E coli	10 7	4	41 ± 7	222 ± 2	526 ± 105		
E coli	71 8	4	37 ± 4	117 ± 0	625 ± 30		
			26 day study with *H eutropha*				
Casein	12 0	4	85 ± 8	300 ± 18	460 ± 41	143 ± 15	33 ± 2
Casein	50 0	4	135 ± 6	315 ± 8	668 ± 23	329 ± 28	36 ± 1
H eutropha	17 0	4	101 ± 9	326 ± 11	545 ± 16	236 ± 24	43 ± 1
H eutropha	72 0	4	72 ± 11	266 ± 4	896 ± 124	483 ± 17	130 ± 10

When the results of this feeding study (Table 1) were examined, the only statistically significant changes observed between groups at the same level of dietary protein were the food and water consumption on the high protein diets The rats ate less of the *E coli* diet ($P < 0\ 05$) (*t* test) and drank more water ($P < 0\ 05$) This experiment verified the hypothesis that diets containing very large amounts of bacteria are not very harmful to the animals after they have been fed on the diets for 14 days.

Subsequently, we made a longer study with *H. eutropha*. The bacteria were grown heterotrophically as a single batch in a 250 gallon fermentor on a medium containing salts, casein hydrolysate, protopeptone, yeast extract and sucrose (Grain Processing Corporation, Iowa). After the cells had reached full growth (24 h), they were prepared as described for *E. coli*. We formulated the diet in a slightly different way from that with *E. coli* in the hope of increasing acceptability. Thus 17 and 72 per cent dry weight of cells were mixed with 10 per cent cottonseed oil, 10 per cent sucrose, 5 per cent *USP* XIV salt mixture (plus 16.5 mg $ZnSO_4$/100 g diet), 2 per cent α-cellulose, vitamins, and the remainder corn starch. Similar control diets were prepared containing 12 and 50 per cent casein. In this case, an equal weight of water was added to all the diets. The rats (67 ± 3 g) were kept as pairs in metabolic cages. The diets were kept at 4° C and were fed fresh to the rats daily for 26 days; food and water consumption and urine and faeces excretion were recorded daily.

When 17 per cent *H. eutropha* was compared with 12 per cent casein in the diet, growth, food and water consumption, and urine excretion were the same (Table 1); excretion of faeces was increased. These data agree with the findings with *E. coli* that whole bacterial cells are digested and provide protein with approximately the same biological value as casein. When *H. eutropha* was fed at a much higher level (72 per cent), however, there was a highly significant ($P < 0.01$) decrease in growth rate and food consumption when compared with the casein control. In addition, the excretion of urine and faeces was significantly increased ($P < 0.05$) with the diet containing *H. eutropha*. The increased production of faeces is probably related to non-digestible components of the bacteria such as cell walls. The ash content of the *H. eutropha* diets was appreciably greater than the corresponding controls and may explain in part the increased urine excretion.

On the basis of these experiments, bacterial cells may be an adequate sole source of protein for extended periods when present at low levels in the diet. When fed at a high level for a period of 26 days, *H. eutropha* does not seem to provide as good nutrition to weanling rats as does a conventional protein. Consideration will have to be given to the problems of increased waste production in any speculation about the use of bacteria as a food for space flights of long duration, as man excretes the less soluble uric acid as a catabolite of the purines rather than as allantoin as does the rat.

Brood-protection in a Deep-sea Holothurian, *Oneirophanta mutabilis* Théel

BROOD-PROTECTION is known to occur in thirty species of holothurians belonging to the orders Dendrochirota and Apoda. All are littoral–sublittoral and most are inhabitants of cold seas, especially the Antarctic. The brood-protecting Dendrochirota usually carry their young on the body-surface or in pockets invaginated from the body-surface. Some Dendrochirota and most of the brood-protecting Apoda have a coelomic incubation, the juveniles passing through a free-swimming stage in the body-fluid of the mother. The Antarctic synaptid *Taeniogyrus contortus* (Ludwig) breeds the young within the ovaries, which they leave at a length of 3 mm (the adult specimens measure 20–45 mm) (ref. 1).

To this hitherto isolated case of intra-ovarial brood-protection in holothurians can now be added that of the deep-sea holothurian, *Oneirophanta mutabilis* (family Deimatidae, order Elasipoda). Brood-protection in this species was found during dissection of twenty-seven specimens, 40–95 mm long, from the Galathea st. 716 off the Pacific coast of Central America (9° 23′ N., 89° 32′ W., 3,570 m deep).

Five females had between one and six young, 7–30 mm long, present in the ovaries (Fig. 1). The smallest specimen with young was 70 mm long and contained three juveniles measuring 7–8 mm. The two largest young, both 30 mm long, were present in a 75 mm long specimen.

Eggs were absent in the ovaries of the females which were bearing young. The other females contained very scattered and small eggs in the ovarial wall, in one female some eggs reached a size of 0.2 mm. The absence of intermediate stages between ovaries in an early stage of egg-formation and ovaries with young in an advanced stage suggests the existence of a reproductive periodicity in this deep-sea species. The females with no young are up to 90 mm long and most of them are probably at the beginning of a new reproductive cycle after the young have been born.

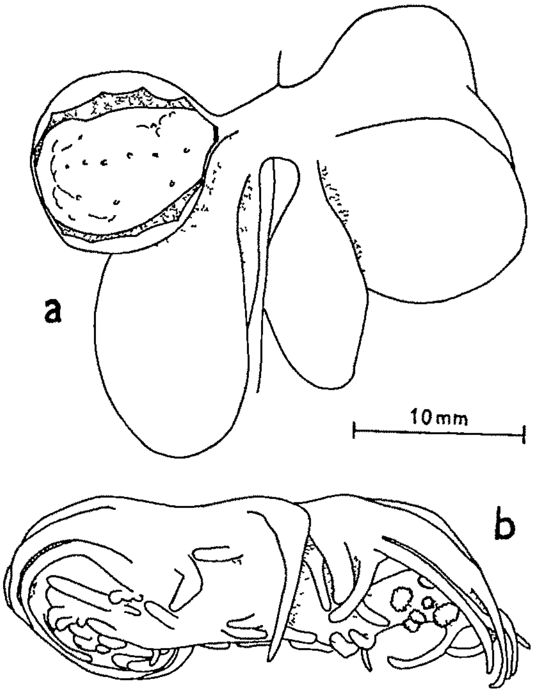

Fig. 1. *Oneirophanta mutabilis*. *a*, Ovary, ventral view, one sac opened to show a young. *b*, Large young from another ovary.

The smallest young had few and minute tubefeet and papillae and five oral tentacles, while the largest had fully developed tubefeet and papillae and ten oral tentacles These juveniles differ from the free-living specimens by the feeble development of the calcareous spicules of the skin and by the lower tentacle-number, the number in free-living specimens being eighteen to twenty

In the earlier stages, the young may feed on the unfertilized eggs The fact that the young increase in size from 7 to 30 mm in ovaries emptied of eggs suggests, however, that they are nourished by a nutritive fluid secreted into the ovaries

An intra-ovarial brood-protection exists also in a few Antarctic species of ophiurans[2,3], but is otherwise unknown in the echinoderms

Production of Hydrogen Sulphide by a Thermophilic Blue-green Alga

LIGHT has been found to stimulate the production of hydrogen sulphide in the unicellular blue-green alga *Synechococcus lividus* Copeland (axenic clone *Y* 52) The culture was initially isolated in 1964 from one of the Fairy Springs, Lower Geyser Basin, Yellowstone National Park The cells were collected at 52° C and the thiosulphate ion content of the water was probably about 9 0 p p m (ref 1)

Although no other organism has been found to exhibit a light stimulated production of hydrogen sulphide gas, several other dissimilatory reductions have been described which may be similar to the production of hydrogen sulphide Among these are the evolution of hydrogen gas in *Rhodospirillum rubrum*[2], *Scenedesmus*[3], *Chromatium*[4] and spinach chloroplast preparations[5] *Chromatium* reduced elemental sulphur to hydrogen sulphide in the dark, but returned to sulphur oxidation when illuminated[6] The non-photosynthetic sulphur bacterium *Desulfovibrio* is a dissimilatory sulphate reducer which can utilize sulphate as its terminal electron acceptor in anaerobic respiration[7] Certain organisms are capable of using nitrate as a terminal electron acceptor A respiratory nitrate reductase has been described for several bacteria and fungi[8] and for the green alga *Chlorella pyrenoidosa*[9] This communication describes preliminary experiments designed to clarify the relationship of hydrogen sulphide production in both light and darkness to the various reductions mentioned

Experimental cultures were grown at 800 lm/ft ² (tungsten) and 45° C in the following defined medium (medium *C*) 1 l of distilled water, 0 1 g of nitrilotriacetic acid; 0 5 ml of trace element solution (1 l of water, 3 0 ml of concentrated hydrochloric acid, 2 0 g of manganese chloride 4 H_2O, 0 5 g of zinc nitrate 6 H_2O, 0 5 g of boric acid, 0 025 g of cupric chloride 2 H_2O, 0 025 g of sodium molybdate 2 H_2O, 0 025 g of cobaltous chloride 6 H_2O, 0 025 g of vanadyl sulphate 16 H_2O), 1 0 ml of ferric chloride solution (0 2805 g of ferric chloride in 1 l of water), 0 0825 g of calcium nitrate 4 H_2O, 0 1023 g of magnesium nitrate 6 H_2O, 0 0077 g of sodium chloride, 0 1032 g of potassium nitrate, 0 6888 g of sodium nitrate, 0 1111 g of sodium mono H phosphate, and 0 9862 g of sodium thiosulphate The *p*H was adjusted to 8 2 with sodium hydroxide, and was about 7 5 after autoclaving The substitution of 0 6 g of calcium sulphate 2 H_2O and 0 0988 g of magnesium sulphate 7 H_2O for sodium thiosulphate produced a good general medium for the growth of thermophilic blue-green algae (medium *A*).

For the experiments, cells were concentrated by centrifugation (5,000*g* at 0° C) The cells were resuspended and washed three times in Sigma buffer (Table 1) The hydrogen sulphide evolved was trapped in 4 M sodium hydroxide placed in the centre well of 15 ml conical Warburg flasks and determined to be sodium monosulphide by the colloidal lead method[10]

Table 1 PRODUCTION OF HYDROGEN SULPHIDE AS μg/g DRY WEIGHT/h $\left(Q^{N_2}_{H_2S}\right)$ IN THE PRESENCE AND ABSENCE OF THIOSULPHATE ION

	Thiosulphate present	Thiosulphate absent
Light	932–1,044 ($\bar{x}$ = 1,024, five trials)	0 (four trials)
Dark	152–244 (x = 168, four trials)	0 (four trials)

The Warburg flasks contained whole cells of *S lividus* in 3 ml of the following Sigma buffer (expressed in μmoles/3 ml of water) 100 μM *tris* HCl buffer (*p*H 6 8), 3 5 μM magnesium chloride 6 H_2O, 10 μM potassium chloride, 10 μM potassium monohydrogen phosphate, 40 μM sodium thiosulphate (when used) The light intensity was 2,600 lm/ft ² and the temperature was 45° C with nitrogen as the gas phase

The cells evolved hydrogen sulphide gas in the light and dark when incubated under nitrogen with either sodium sulphate or thiosulphate Fig 1 shows that the production of hydrogen sulphide gas in the light was constant over the experimental period, that the rate of gas production when the culture was supplied with thiosulphate was twice that of the sulphate culture, and that with either salt the rate in the light exceeded the respective dark rate by a factor of ten

Several bacteria[11] and fungi[12] have been shown to evolve hydrogen sulphide gas by the action of cysteine desulphydrase on L-cysteine, so *S lividus* was assayed for this enzyme Assays in both the clarified and broken-cell preparations were negative[13]

The formation of hydrogen sulphide gas required an exogenous source of sulphur in both the light and dark (Table 1) Sulphur reduction occurs in micro-organisms of nearly all nutritional types, and may occur independently of photosynthesis Nevertheless, it is possible when sulphur reduction, either assimilatory or dissimilatory, and photosynthesis take place in the same organism

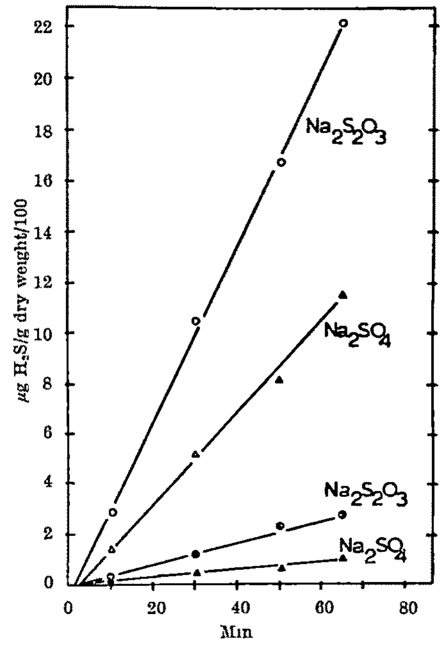

Fig 1 The production of hydrogen sulphide by *S lividus* in the light and dark The flask contained 3 ml of Sigma buffer (see Table 1) with either sodium sulphate or thiosulphate, 40 μM/3 ml The centre well contained 0 3 ml of 4 M sodium hydroxide as a sulphide trap The temperature was 45° C, the light intensity was 2,600 lm/ft ² and the gas phase was nitrogen ○ and △, Light, ● and ▲, dark

that the two processes are closely linked as in the reduction of molecular nitrogen[14], nitrate[15,16] and sulphate[17,18]

If water serves as the electron donor in anaerobic dissimilatory sulphate photoreduction, then the addition of a substitute electron acceptor in the form of sulphate or thiosulphate should result in an increased rate of oxygen evolution The maximum stimulation should be obtained when other reducible substances, such as carbon dioxide, are excluded and when the light is saturating for photosynthesis. Fig 2 compares the rates of oxygen evolution during the reduction of thiosulphate or sulphate with a control lacking an exogenous sulphur electron acceptor Clearly, the addition of either sulphate or thiosulphate stimulated the rate of oxygen evolution, both serving equally well as shown by the nearly identical rates, approximately double that of the control

Fig 3 illustrates the same effect using a Clark silver-platinum oxygen electrode The cells, initially in anaerobic conditions, responded to the injection of an anaerobic thiosulphate solution with an increased rate of oxygen evolution, approximately double that of the preceding rate

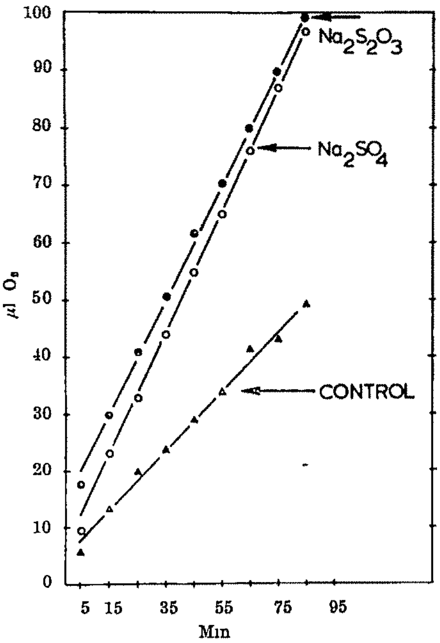

Fig 2 The effect of exogenous sulphate and thiosulphate on oxygen evolution in *S lividus* The flask contained 3 ml of Sigma buffer (see Table 1) with or without sodium sulphate or thiosulphate, 40 μM/3 ml The centre well contained 0 3 ml of 4 M sodium hydroxide as a sulphide trap The temperature was 45° C, the light intensity was 2,600 lm/ft^2 and the gas phase was nitrogen

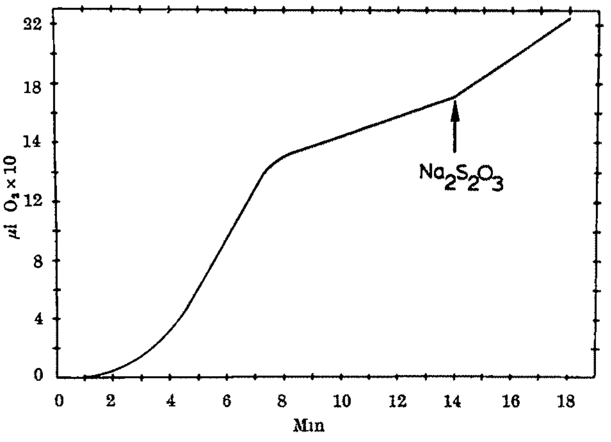

Fig 3 Oxygen production (corrected for respiration) by *S lividus* before and after the addition of sodium thiosulphate, 40 μM/3 ml The reaction mixture was Sigma buffer (see Table 1), the temperature was 45° C, the light intensity was 2,600 lm/ft^2 and the gas phase was nitrogen The curve shows an initial oxygen burst after the onset of illumination at time zero, a subsequent equilibrium rate and a higher equilibrium rate after the addition of thiosulphate

The stoichiometric relationship of sulphur reduction in *S lividus* to photosynthesis and respiration in anaerobic conditions will be reported later

Effect of Seed Extract of *Trifolium subterraneum* on Germination and Seedling Growth Rate

Seeds may contain water-soluble substances which inhibit or retard germination[1] This communication reports the effects of a water-soluble extract from the seed of *Trifolium subterraneum* L (subterranean clover) on the germination and growth of subterranean clover and wheat

A water-soluble extract was prepared by soaking 200 g of commercial seed of subterranean clover (cultivar 'Mt Barker', 208 seeds/g) in 300 ml of distilled water for 24 h at 30° C The solution was then evaporated at 100° C and the resulting crystals were finely ground A quantity of extract was also freeze-dried The effect of the freeze-dried solution on subsequent germination and growth of subterranean clover at 30° C was similar to that of the material evaporated at 100° C The results only refer to an extract evaporated at 100° C.

Seeds of subterranean clover ('Mt Barker') were germinated in the dark at 18°, 23° and 30° ± 1 5° C All combinations of the three temperatures, and five relative concentrations (0, 25, 50, 75 and 100, where 100 = 1 g of extract/16 ml of water) were tested, using five replicas each of 100 graded seeds (135 seeds/g) The seeds were placed in Petri dishes, so that they were partially immersed in 10 ml. of the solution, and the Petri dishes were hermetically sealed After 3 days, germination, based on emergence of the radical, was recorded The length of the radical of germinated seeds was used as a measure of the initial rate of growth By this time and in these conditions the hypocotyl had not elongated To test the extract for non-specificity, its effects on the germination of growth rate of wheat (variety 'Falcon') were examined at temperatures of 18°, 25° and 30° ±1 5° C Fifty seeds were used in each replicate. A wider range of concentration of extract was tested as shown in Fig 2 Germination was recorded based on the emergence of both coleoptile and primary root, and lengths of these organs gave a measurement of growth

The results of the germination tests for subterranean clover are given in Fig 1*a*. There was no significant effect of the extract on germination at 18° C, but with increasing temperature and concentration germination was markedly reduced Fig. 1*b* shows the effect of temperature and concentration of the extract on the length of the radicle There was no effect of temperature in the absence of the extract At 18° C and 23° C the length of the radicle decreased with increasing concentration, with little differential effect caused by temperature At 30° C there was a particularly marked effect at relative concentration 25, but increasing the concentration had no further effect

Many of my experiments have shown that the germination and growth rate of subterranean clover in hermetically sealed dishes at minimum moisture tension are unaffected by temperatures in the range 18°–30° C The finding that the percentage of germination of control material at 30° C is not significantly reduced differs from the results reported by Ballard[2]. A typical experiment showed that the percentage of germination of imbibed seed in these conditions was reduced by at least 50 per cent when dishes were not sealed. Differences in the methods of germination may be responsible for the apparent discrepancy with Ballard's results

The effects of temperature and concentration of extract on the germination of wheat are shown in Fig 2*a* Again, the extract was most effective at 30° C and least effective at 18° C At 30° C relative concentrations 0 5, 1, 2 5, 5 and 10 had a stimulatory effect on germination. Fig 2*b* shows the effect of temperature and concentration of an extract on the length of the coleoptile In the absence

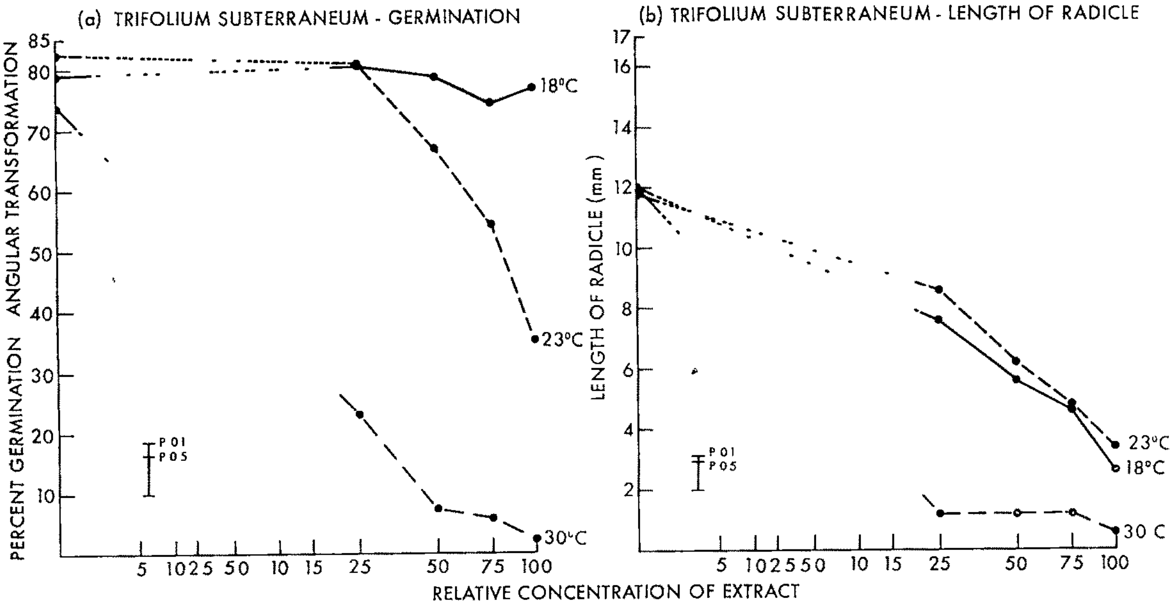

Fig 1 Effect of temperature and concentration of extract on ,germination of subterranean clover, *b*, radicle length of subterranean clover

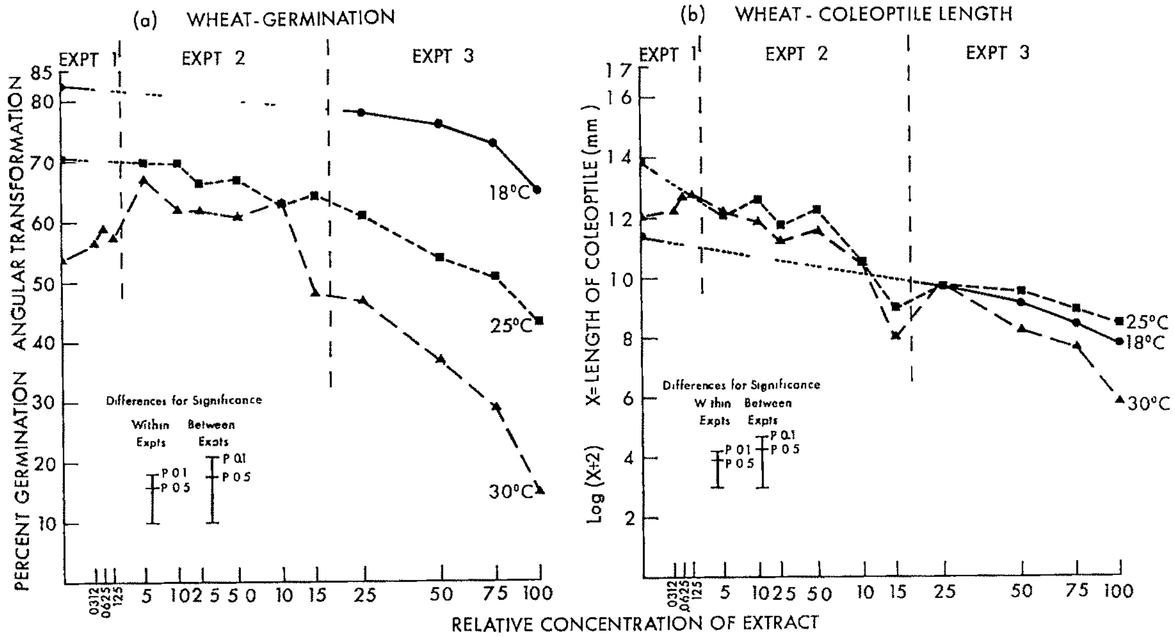

Fig 2 Effect of temperature and concentration of extract on *a*, germination of wheat, *b*, coleoptile length of wheat

of extract, growth rate is less at 18° C and 30° C than at 25° C At all temperatures there was a marked effect of the extract on the length of the coleoptile at relative concentrations of 25 and over The effect of temperature and concentration of extract on the length of the primary root was usually similar to that for coleoptile length

The osmotic pressure of the solution at a relative concentration of 100 was only 5 4 atm as determined by the vapour pressure method At 30° C, pressures of 5 atm have been shown to have only a slight effect (about 10 per cent reduction) on the germination of subterranean clover seed (personal communication from R M Moore) There is no effect of such an osmotic pressure at lower temperatures The reduction of about 75 per cent in germination of subterranean clover at 23° C and 30° C obtained in this work can be attributed therefore to an inhibitory effect of the extract

The effect of the extract on both subterranean clover and wheat is maintained only if the seed remains in contact with the solution The viability of seeds which had not germinated after three days was tested by washing thoroughly in distilled water, and germinating at a favourable temperature The seeds from all treatments germinated readily, even after they had been soaked for three days at relative concentration 100 at 30° C It was observed, however, that there was a residual effect of the extract on the growth rate of the radicle of subterranean clover, the effect increasing with increasing concentration

The results show that seed of subterranean clover contains a water-soluble substance or substances which at high concentrations adversely affect germination and growth This inhibitory effect is strongly dependent on temperature and seems to be non-specific

A recent paper[3] has been brought to my attention since this publication was prepared The hypothesis of Taylor and Rossiter that a water-soluble inhibitor of germination is involved in the regulation of germination of new (dormant) seed is extended by the results of the present study The magnitude of the inhibitory effect obtained in this study may vary with cultivar and seed-lot as suggested by Taylor and Rossiter

Taxonomic Significance of Carotenoids

Goodwin[1], reviewing the distribution of carotenoids in non-photosynthetic tissue, came to the conclusion that it was very difficult to see their taxonomic significance Rubixanthin seemed to be restricted to *Rosa* spp [2] and it was suggested that, if a carotenoid mixture contained significant amounts of rubixanthin, then one could say with some confidence that the source of rubixanthin was the hips of a species of *Rosa*[1] Rubixanthin, however, has been identified in several other plants, namely, *Cuscuta salina*, *C subinclusa*[3] and *Gazania rigens*[4] Valadon[5] has also identified this pigment in the orange peel fungus, *Peziza* (*Aleuria*) *aurantia*, but Jensen[6] failed to confirm this result and had found a new pigment With a view to finding whether rubixanthin was restricted to some members of the higher plants, we have reinvestigated the carotenoid composition of the orange peel fungus

A number of specimens of *Peziza aurantia* were extracted in methanol and the carotenoids were separated and identified by our usual procedures[7] The following pigments were characterized β-carotene, γ-carotene and aleuriaxanthin ester, lycopene and 3,4-dehydrolycopene, in agreement with Liaaen Jensen's findings[6] Several other pigments, however, were identified α-carotene, neurosporene and rubixanthin, which were not in Jensen's specimens There were also four other carotenoids that could not be positively identified because they were found in too small an amount One such pigment was strongly adsorbed on the MgO–'Celite' column, was found as the top band, had the same absorption spectrum as γ-carotene and might be aleuriaxanthin[6] Rubixanthin was present and it was identified by its absorption spectrum and its position on an MgO–'Celite' column It also did not separate from pure rubixanthin using circular chromatography This was achieved with paper loaded on 22 per cent silica gel and eluted with 1 per cent acetone in *n*-hexane The amounts of carotenoids separated from *Peziza aurantia* are shown in Table 1

Table 1 CAROTENOID COMPOSITION OF *Peziza* (*Aleuria*) *aurantia*

Carotenoids	Amount (μg/g)	Per cent
α-Carotene	2 0	0 3
β-Carotene	300 5	43 9
Unknown (418, 443, 470)	4 3	0 6
γ-Carotene	106 4	15 5
Neurosporene	28 8	4 3
Rubixanthin	67 7	9 9
Aleuriaxanthin	146 9	21 5
Lycopene	11 8	1 7
3,4-Dehydrolycopene	5 5	0 8
Unknown (475, 486)	5 0	0 7
Unknown (416, 440, 467)	3 2	0 5
Unknown (435, 460, 487)	2 5	0 3
Total carotenoids	684 6	100

It is well known that plants from different geographical habitats and of different species differ with respect to their carotenoid composition[1,7] Fungi seem to be no exception It has been shown that ultraviolet irradiation can alter the pigment composition in fungi[8] and one may conclude that in different conditions of light and temperature it is possible to have changes in the quantities as well as in the qualities of the pigments involved It is not unexpected therefore to find different pigment composition in the same species of fungi in different parts of the world The evidence presented shows that carotenoids may not be useful as a taxonomic character

We thank Mrs Pat Andrews for the specimens of *Peziza aurantia*

MICROBIOLOGY

Action of Bacteriophages obtained from *Corynebacterium diphtheriae* on *C. ulcerans* and *C. ovis*

The value of phage-typing in studying the strains of bacteria responsible for certain infections raised the question of whether phage-typing might also be valuable in epidemiological studies of diphtheria Early investigations on this subject have already been reported[1–6]. Most of these earlier studies were restricted by the very small numbers of bacteriophages that had been isolated from *C. diphtheriae* up to that time, and of suitable sensitive indicator strains for demonstrating and propagating new phages. The decline in the incidence of diphtheria in many countries after the adoption of widespread prophylactic vaccination has reduced the incentive to pursue these lines of investigation. In some countries, however, diphtheria epidemics continue to be an important public health problem. This fact, together with the predominance of one biotype of *C. diphtheriae* in certain regions over a number of years—for example, type *gravis* in Romania and type *intermedius* in the German Democratic Republic (East Germany)[7]—has stimulated further studies in phage-typing as a possible means of providing more detailed information concerning the characteristics of strains involved within a prevailing biotype[7-10]. Arising from studies on some thousands of strains isolated over the period 1954–64 in the Diphtheria Department of the Cantacuzino Institute, Bucharest, Romania, Saragea and Maximesco proposed a provisional scheme of phage-typing of *C. diphtheriae*[7]. This involves the use of twenty-four diphtheria phage preparations by means of which nineteen lysotypes of *C. diphtheriae* have been recognized, not by the lysis of strains of *C. diphtheriae* by single phages, but on the basis of the characteristic pattern of their reactions to one or more test phages.

Saragea and Maximesco[7] and Meitert *et al.*[11] failed to obtain evidence of lysis when their diphtheria phages were tested on a series of strains of pathogenic *Corynebacteria* other than *C. diphtheriae*, including seventeen strains of *C. pyogenes*, thirteen of *C. equi*, nine of *C. renale*, two of *C. murium*, two of *C. ovis*, and seven unclassifiable strains from bronchopneumonia in pigs. These observations suggested that the diphtheria phages used in Saragea and Maximesco's proposed scheme of phage-typing were specific for *C. diphtheriae*.

In the course of our own studies on the relationship between *C. diphtheriae*, *C. ulcerans* and *C. ovis* (*C. pseudotuberculosis*), the opportunity was offered, through a gift from Dr Saragea, of the twenty-four test phages derived from *C. diphtheriae* used in her phage-typing scheme, to test the lysosensitivity to these phages of fifty-two strains of *C. ovis* (sixteen ovine, twenty caprine, fourteen equine and two bovine), and fifty-six strains of *C. ulcerans* (forty-nine human, seven bovine).

The method of testing was that used by Saragea[7] of spotting phage preparations on lawns of young cultures of the bacterial strains to be tested. All tests were carried out with the same preparations of phages which throughout the period of these experiments showed no significant loss of activity on their sensitive indicator strains of *C. diphtheriae* which were included as controls with most tests.

Some strains of *Corynebacteria* of all groups of both *C. ovis* and *C. ulcerans* showed lysis by one or more of the twenty-four diphtheria phages, the proportion of sensitive strains ranging from 44 per cent in ovine strains of *C. ovis* to 86 per cent in both equine strains of *C. ovis* and bovine strains of *C. ulcerans*.

Every one of the twenty-four diphtheria phages produced lysis of some of the strains tested, but at no time did the pattern of lysosensitivity of any strain of *Corynebacterium* exactly match that of any of the lysotypes of *C. diphtheriae* included in Saragea and Maximesco's proposed scheme of phage-typing.

Some degree of uniformity of pattern of lysosensitivity was evident within lysosensitive strains belonging to certain groups of the *Corynebacteria* tested. There were also differences between such patterns in different groups. Assessment of the validity and significance of such apparent patterns must await further observations on additional strains and a wider range of phages. The results suggest, however, the possibility that significant differences exist between these closely related *Corynebacteria*. The reactions to nine of these diphtheria phages are of special interest because of the high proportion of sensitive strains among caprine and equine strains of *C. ovis* and in both human and bovine strains of *C. ulcerans*. Furthermore, of these nine phages, five produced a high proportion of complete or almost complete (clear) lysis, whereas most plaques with other strains were of the cloudy type.

These observations indicate that although Saragea and Maximesco[7] and Meitert *et al.*[11] found no evidence of lysosensitivity to their diphtheria phages among fifty strains from more than five species of pathogenic *Corynebacteria* of animal origin, when these same phages were tested on a more extended range of strains of *C. ovis* and *C. ulcerans* (two species not well represented in their series), numerous lysosensitive organisms were revealed. It is therefore clear that the twenty-four phages isolated from *C. diphtheriae* which have been employed by Saragea and her colleagues are not completely specific for *C. diphtheriae*.

The part played by bacteriophage infection in determining toxinogenicity in *C. diphtheriae*, first revealed by Freeman[12], raises a number of interesting questions concerning the occurrence and effects of cross-infections by bacteriophages between different species of pathogenic *Corynebacteria*. The foregoing observations were made as part of a general study of this question and full details will be reported elsewhere.

I thank Dr Alice Saragea and Dr H. Rische for diphtheria phages and sensitive indicator cultures. I also thank Professor R. I. N. Greaves for facilities in his department. This work was supported by a grant from the Medical Research Council.

CYTOLOGY

Polymelanosomes of the Melanocyte and their Substructures

THE importance of studying visceral melanocytes has already been emphasized[1-4] and the liver of *Amphiuma tridactylum*—a rich source of melanocytes—is a suitable material to use. The melanoprotein of the liver of *Amphiuma* is very similar to that of human liver melanoma[5], and the melanin polymer (free from protein) closely resembles that of human substantia nigra pigment and synthetic catecholamine pigment formed by incubating the various amines with a mitochondrial preparation containing monoamine oxidase[4]. Structural and functional studies of the hepatic melanocytes of *Amphiuma* may therefore have a bearing on other pigmentary systems. We have reported (refs. 1 and 6 and unpublished work of Prasad) that the melanocytes of *Amphiuma* constitute about 20 per cent of the liver cell population (hepatocytes and melanocytes). Most of these melanocytes (70–80

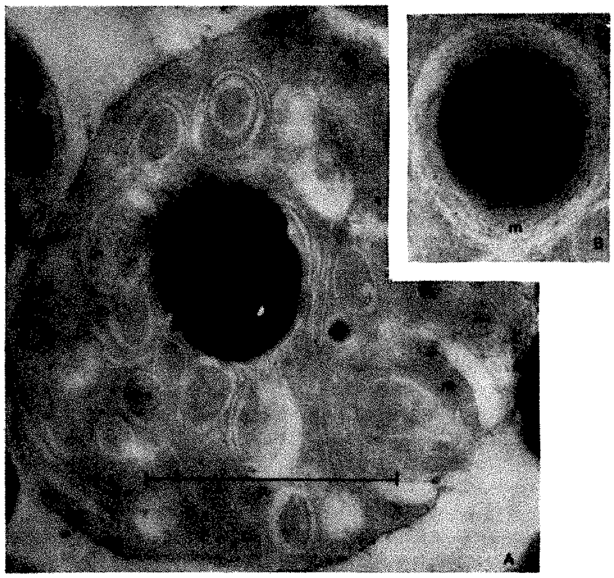

Fig. 1. *A*, An isolated polymelanosome from *Amphiuma* liver. Note the unmelanized structures which probably represent melanosomes (ms). Concentric membranes (m) surround both melanosomes and melanin granule. (× *c*. 33,260.) *B*, A melanin granule surrounded by several concentric membranes (m).

per cent of total pigment cell population) are lightly pigmented and have an abundance of melanin-containing organelles which we named polymelanosomes[6]. The darkly pigmented cells contain closely packed granules lying freely in the cytoplasm, but no polymelanosomes. There is some morphological evidence that melanin-synthesis occurs in the polymelanosomes, and the light melanocytes which have an abundance of these organelles probably represent the younger form[6]. Polymelanosomes possess three mitochondrial enzymes, monoamine oxidase, cytochrome oxidase and succinic oxidase[7].

We have studied isolated polymelanosomes of *Amphiuma* liver melanocytes in greater detail. Recently negative-contrast staining has been used to visualize membrane structures of mitochondria[8], and we have used a similar technique to study the membrane structures of polymelanosomes. The question also arises as to whether or not polymelanosomes are unique to *Amphiuma* liver melanocytes; thus we have investigated melanocytes in the skin and eye of *Amphiuma*, the liver of *Necturus maculosus* (mud-puppy), frog and alligator and the substantia nigra of monkey and human.

Polymelanosomes and their membrane structures were isolated by the method of VanWoert *et al.*[7] with a slight modification[6]. This procedure gave a good yield of polymelanosomes. (The polymelanosome fraction was not contaminated with mitochondria and polysomes, but occasionally a nucleus or partly broken cell was present. Thus our polymelanosome fraction was as pure as that of Van Woert *et al.*[7].)

For negative staining, the isolated polymelanosomes were suspended in 2–3 ml. of standard buffer which contained no sucrose, and were broken either by sonication at 1 mA for 20 s or by homogenization in a Potter-Elvehjem homogenizer, and centrifuged at 1,000*g* for 5 min to remove melanin granules. The supernatant, melanin granules and unbroken polymelanosomes were negatively stained by placing a small drop of each fraction on a grid and blotting the excess fluid. It was stained in 1 per cent uranyl acetate for 10–20 s and examined with an electron microscope at 100 kV. To investigate the presence of polymelanosomes in other organs, samples of skin and eye of *Amphiuma*, liver of *Necturus maculosus* (mud-puppy), frog and alligator, and substantia nigra of monkey and human were fixed and stained for electron microscopy as described earlier[7]. The human substantia nigra was fixed within 3 h after death. The monkey brain was fixed *in vivo* by perfusing glutaraldehyde through the carotid artery and the pigmented portion of the substantia nigra was excised and processed for staining as described earlier.

Fig. 1*A* is an electron micrograph of an isolated intact polymelanosome of a hepatic melanocyte of *Amphiuma* which shows a single melanin granule and several less electron-dense areas probably representing melanosomes. Two to seven concentric membranes surround both the melanosomes and melanin granule. Fig. 1*B* shows a melanin granule surrounded by concentric membranes. On the basis of morphology, it seems as though melanin polymer is being laid down on the melanosomes. This observation is consistent with the present concept of formation of the melanin granules. Such a clear demonstration of the morphological apparatus of melanogenesis has not been encountered, however, in other tissues. The part played by the concentric membranes in melanogenesis, if any, remains uncertain.

We have studied the membrane structures of polymelanosomes by negative staining. The isolated polymelanosomes were broken by homogenization or sonication and the melanin granules were removed before staining. Many structures are present in the supernatant fraction (Fig. 2), and small spherical bodies are associated with large ones. With a few exceptions, the average diameter of the small bodies is 430 Å (ranging from 250 Å to 600 Å). A single melanin granule is also visible but polysomes or ribosomes were not seen in this preparation. Polymelanosomes broken by sonication or by homogenization have the same substructure. The melanin granule pellet does not contain any spherical bodies. The fraction containing unbroken polymelanosomes shows several melanin granules and a few small bodies; the negative staining does not show the internal structures of the intact polymelanosomes. We do not know whether these large bodies are an integral part of the polymelanosomes *in vivo* or are formed during preparation of the fraction. The uniformity of the small bodies and the presence of structures similar to those of the large bodies in the section of an isolated polymelanosome indicate that the latter is a possibility. The significance of these substructures in polymelanosomes, if any, remains obscure.

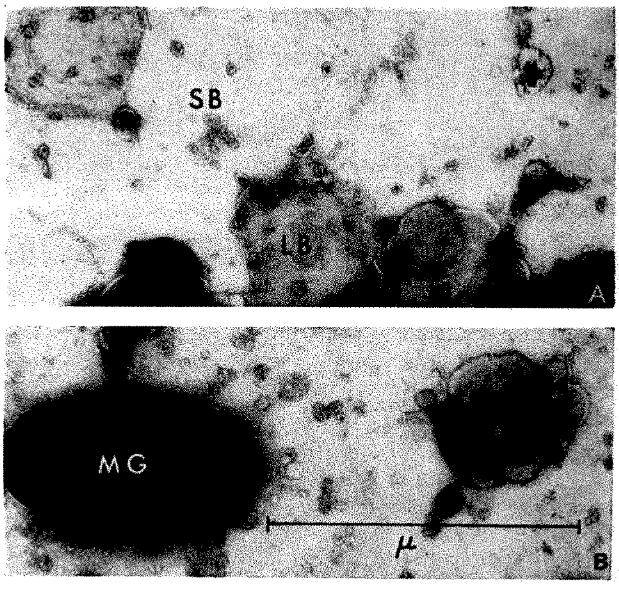

Fig. 2. Substructures of the polymelanosome. Polymelanosomes were disrupted by homogenization, and the supernatant fraction obtained after removal of melanin granules was stained with 1 per cent uranyl acetate. Many small spherical bodies (SB) are associated with large ones (LB). A single melanin granule (MG) is also seen. (× *c*. 41,670.)

Polymelanosomes similar to those in lightly pigmented melanocytes of *Amphiuma* liver have not yet been demonstrated in melanocytes of the skin and eye of *Amphiuma*, liver of *Necturus maculosus* (mud-puppy), frog and alligator, or the substantia nigra of monkey and human. This should not be surprising, because melanocytes in these organs resemble the dark melanocytes of *Amphiuma* liver which have melanin granules but no polymelanosomes. Thus the possibility still remains that polymelanosomes similar to those in the lightly pigmented melanocyte of *Amphiuma* liver may be found in the younger stage of melanocytes of these organs.

Arrangements of melanin granules bearing some similarities to those of *Amphiuma* liver have been seen before in a variety of tissues as phagocytic vacuoles[9], as conglomerate granules[10], as melanin-building centres[11], as melanin spheres[12], as irregular inclusions[13] or as compound granules[14]. These structures are not as abundant in the cytoplasm of their respective cells as are the polymelanosomes in *Amphiuma* liver melanocytes. They also do not have complex membrane structures similar to those of polymelanosomes. Nor is it known whether these various organelles can maintain their structural integrity after isolation as the polymelanosomes of *Amphiuma* liver melanocytes do.

We thank Dr Horton A. Johnson for many stimulating discussions. This work was supported by the US Atomic Energy Commission and performed at Brookhaven National Laboratory.

Ability of Haematopoietic Spleen Colonies to form Macrophages *in vitro*

THERE is substantial evidence that blood monocytes are the immediate precursors of macrophages in inflammatory exudates[1,2] and in the peritoneal fluid[3], and that bone marrow is a potential source of these macrophages[3-5]. In previous work using the chromosome marker technique, and *in vitro* cultivation of macrophages, it was shown that in mouse radiation chimaeras, bone marrow is a source of alveolar macrophages and of macrophages which can be cultured from different organs[6]. This work also suggested that only haematopoietic tissues contain precursor cells for macrophages.

In the work reported here the relationship of macrophage origin to the granulocytic and erythrocytic series of differentiation was investigated by establishing macrophage cultures from haematopoietic spleen colonies[7] of different cellular composition. The yield of macrophages was found to be correlated to the type of colony, and dividing macrophages had the same genotype as the donor cells used for the production of the colonies.

Adult male *CBA* mice were given 820 r. using a dual source ^{137}Cs irradiator at a dose rate of 180 r./min. Within 6 h of irradiation the mice were injected with 20,000 nucleated bone marrow cells from $CBA.T_6T_6$ donors. The surviving mice were killed 13–16 days later and their spleens were removed. Individual colonies which were well separated from neighbouring colonies were dissected and cut in half. Imprint preparations were made on sterile slides from the cut surfaces and stained with May–Grünwald–Giemsa (MGG). Half of each colony was dispersed by aspirating in a plastic syringe, incubated in the presence of 0·5 µg/ml. of colcemid and processed for chromosome preparations[8]. The other half was cut into smaller pieces, where necessary, and used for organ cultures as previously described[6,9]. After 2 days the coverslips underlying the organ explants were removed from the grid culture system, and the coverslip cultures were grown separately in small dishes. To induce macrophages to divide, medium in the separate coverslip cultures was supplemented with 50 per cent of used medium from *L* cell cultures, known to contain growth factor(s) for macrophages[10]. Coverslip cultures were processed after 3–4 days for chromosome preparations as described earlier[6]. When duplicate cultures were available, these were stained with MGG for morphological observations.

During the first 2 days, all organ cultures of spleen colonies produced large numbers of round, free-floating cells which dropped on the coverslip underlying the explants. During 3–4 days of incubation in separate culture dishes, most cells degenerated. In most cultures, however, a variable number of cells became attached to the coverslips. These large, stretched cells had the morphological characteristics of macrophages[6], judged by observations of living cultures using an inverted microscope with phase optic and of MGG-stained preparations. The capability of colony explants to produce macrophages was scored visually from + + + (crowded monolayer of macrophages) to – (less than 100 macrophages/coverslip) by observing the living cultures. The type of colony was determined from an imprint preparation stained with MGG. A colony was scored as "erythrocytic" if less than 3 per cent of the cells could be identified as immature or mature granulocytic cells, and vice versa. The rest of the colonies were called "mixed". Erythrocytic colonies showed little ability to produce macrophages. Granulocytic and most of the mixed colonies produced large numbers of macrophages (Table 1). Satisfactory chromo-

some preparations could be obtained only from coverslip cultures with large numbers of macrophages. In all examples, the dividing macrophages had the T_6 marker chromosomes of the bone marrow donor, as did all the dividing cells of the individual colonies (Table 1); thus there was no contribution from the host spleen to the macrophage population.

Spleen colonies seem to result from the proliferation of single stem cells[11], which are pluripotent and capable of giving rise both to differentiated erythrocytic, granulocytic and megakaryocytic cells, and to new colony-forming cells[12]. The present findings suggest that the colony-forming stem cell is also capable of producing progeny which differentiates into macrophages *in vitro*. Macrophage formation seems to be related to the granulocytic series of differentiation. It would be important to establish if the presence of some specific cell type(s) in granulocytic colonies could be correlated to the capability of the colonies to form macrophages.

This investigation was conducted under a contract with the special virus leukaemia programme of the National Cancer Institute, National Institutes of Health, US Public Health Service.

Hypothesis to explain Synapsis of Meiotic Chromosomes

THERE is so far no satisfactory explanation for the synapsis of homologous chromosomes at meiosis[1]. In the past, the process has been attributed to various factors such as electrostatic forces[2], resonance bonding[3], hydrodynamic forces[4] and antigen-antibody formation[5]. The criticisms of these hypotheses have been reviewed by Riley and Law[1]. In this communication I have attempted to explain this phenomenon in molecular terms.

I suggest that the molecular process which, according to Whitehouse[6], results in crossing over is also responsible for synapsis. This process is the formation of hybrid DNA between broken single strands of homologous chromatids, which gives precision of pairing and at the same time establishes bonds between the homologues. Initial contact of the homologues would be made at the chromocentre or more rarely at other places on the chromosomes[7]. From these points of initial contact, the formation of hybrid DNA would then proceed along the chromosomes in both directions in zipper-like fashion. Synaptic (hybrid DNA) bonds would arise from single (primary) breaks in the homologous DNA molecules, while crossing over occurs later, through another set of (secondary) breaks in the other strand of the same DNA helices. Synaptic bonds not involved in crossing over would be removed through an excision-repair process as found in thymine dimer removal[8]. There is still the question of the nature of the initial force which attracts the homologous centromeres to each other. A controlling element in the heterochromatin near the centromeres might have this recognizing and attracting property[9].

This model differs from that of Whitehouse[6] only in the assumption that hybrid DNA itself is responsible for synapsis. For this to be correct the primary breaks must occur before synapsis. This would, in fact, be so if the assumption[10] were correct that the same breaks were involved both in transcription and crossing over; experimental evidence on this point is contradictory[11]. If the same breaks are involved in both processes, then single polynucleotide strands would have to persist from interphase (when transcription occurs) until prophase (when synapsis and crossing over take place). Single strands of DNA are known to be degraded by DNases[12], but such enzymes have so far been detected only in bacteria, and may not be present universally in interphase nuclei.

Various unexplained phenomena of synapsis and crossing over could be fitted into this model of synapsis. Synaptinemal complexes are usually found only in regions of association of chromosomes in the bivalents[13] and may represent regions of hybrid DNA as seen in the electron microscope. The central core could be the region of hybrid DNA itself, while the thin connecting chromatin strands could be single stranded portions of the DNA helices. The lateral components are more difficult to explain.

Several authors[14] have suggested that mutagens may induce mitotic or meiotic crossing over by facilitating pairing of homologues where it is weak or, as in *Drosophila* spermatozoa, does not occur. With the proposed hypothesis, the inducing agents might do this by providing more single strand breaks.

Genetic control of synapsis is a well known phenomenon[15]. Conceivably this, too, may act by means of control of the breaks available for synapsis. Pontecorvo[16] has suggested that in the course of evolution a reduction of crossing over has occurred in somatic cells from a primitive condition in which crossing over was very frequent. One of the evolutionary mechanisms for suppressing crossing over may be shortage of breaks at the appropriate time either because fewer breaks occur or more are repaired before prophase.

I thank Professor C. Auerbach and Dr Brian J. Kilbey for their helpful criticisms.

GENETICS

Cyclopism as a Hereditary Malformation

CYCLOPISM is a malformation which has been recognized for many years and which may have furnished the model for the Homeric monsters. It has been suggested that this developmental disorder is hereditary, but until recently there has been no proof of this.

One of us reported an extra, very small chromosome in 30 per cent of fibroblasts from a cyclops[1]. Some weeks after the report was published the same hospital announced another cyclops whose mother was an aunt to the mother of the first. Attempts to grow fibroblast cultures from the child at birth were unsuccessful. At the same time we started lymphocyte and fibroblast cultures from the mother and initiated an examination of the family. Its pedigree is shown in Fig. 1. Careful discussion of the family history with its different members revealed the birth of two other cyclopes (cases 15 and 17) to two sisters of case No. 7, one being the grandmother (case 5) of the 1966 cyclops (case 26). Both cyclopes had been born at home in 1939 and 1942, respectively, and were described by the mothers. Cases 23 and 26 had been delivered in a hospital. In addition there had been eleven abortions and other proved or probable malformations, and there were only twelve healthy births in the family.

Chromosome counts were carried out for all members of the family except two, and the number was found to be 46. Fig. 2 shows one of twenty karyograms of the mother (case 7) of the most recently born cyclops. A missing third chromosome and a supplementary chromosome in the *C* group are characteristic features. In the best karyograms there is one *C* chromosome as large as the *B* chromosomes, but its short arm is distinctly larger and its long arm a little shorter than the arms of a chromosome of the *B* group. None of the arms resemble a normal third chromosome. So far we have not been able to decide whether this *C* chromosome is really changed or only less spiral. Detailed autoradiographic studies and control of secondary constrictions will perhaps solve this problem.

Identical karyograms are found in the three healthy sisters (cases 3, 5 and 6), their father (case 1) and in the third generation in the mother (case 13) of the 1966 cyclops. Fifteen to twenty karyograms were controlled from each person.

The most probable explanation is that a translocation from a third chromosome to a *C* chromosome and eventually to the *X* chromosome is balanced in the healthy persons 1, 3, 5, 6, 7 and 13. Case 1 transmitted it to his four daughters. One male and one probably male abortion could be unbalanced. The quadrivalent ring or chain formation in the meiotic division of the daughters led to meiotic accidents, such as the extra very small chromosome of the 1966 cyclops[1]. The deletion of a small chromosome segment probably led to cyclopism four times. Other distributions of the structurally changed chromosomes could explain at least some of the abortions and different malformations.

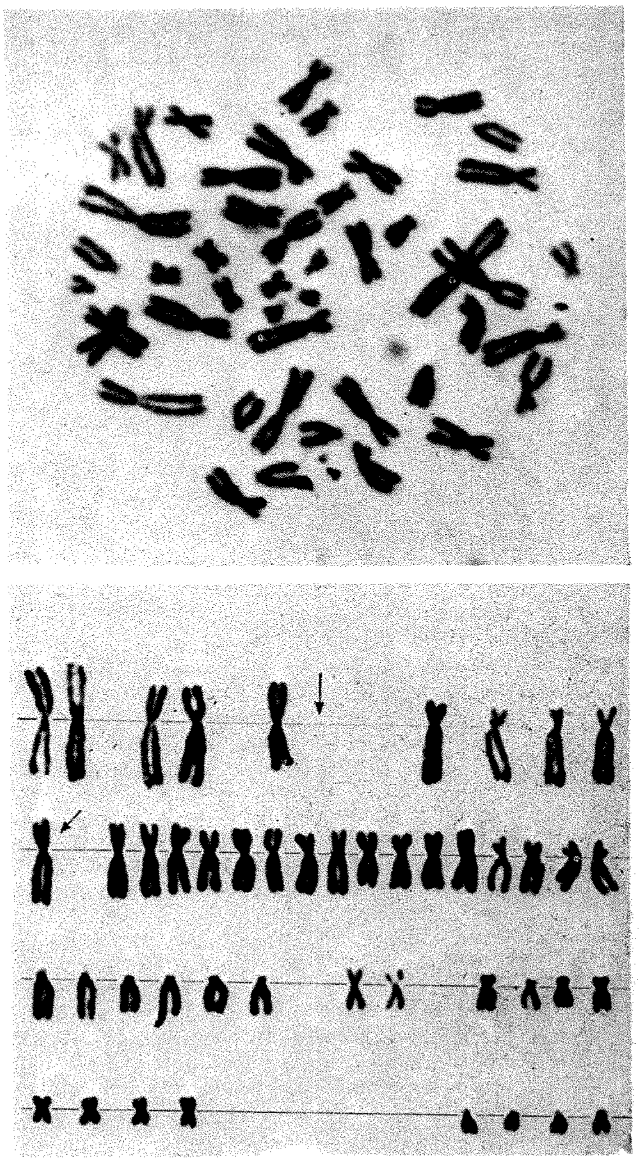

Fig. 2. Karyogram of one of the mothers of the cyclopes (case 7) (× 1,300).

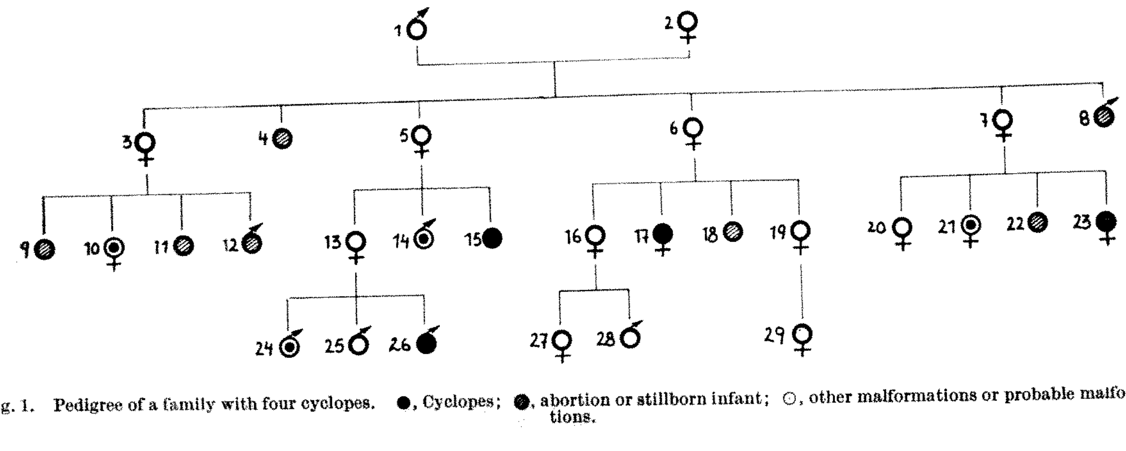

Fig. 1. Pedigree of a family with four cyclopes. ●, Cyclopes; ◍, abortion or stillborn infant; ○, other malformations or probable malformations.

Together with the twins of Ellis[2], the two brothers of Klopfstock[3], the three children in the family described by Dominok and co-workers[4], the arrhinencephalic two sisters of DeMyer and co-workers[5], this is another case of family cyclopism or related malformations, the four different mothers being relatives and showing the same chromosomal aberration. The hereditary character of the malformation seems to be beyond doubt in our case. We hope that other translocation patterns will allow localization of the cyclopism-locus on one of the two involved chromosomes one day.

PATHOLOGY

Sarcomas in Afghanistan

SARCOMAS in general receive much less attention than carcinomas. There are two reasons for this: first, sarcomas are considerably outnumbered by carcinomas in most populations and, second, environmental, that is, avoidable, factors have been more often aetiologically related to carcinomas than to sarcomas. For these reasons I have made this investigation. In Afghanistan, sarcomas are not greatly outnumbered by carcinomas and I shall suggest that there may be an aetiological relationship between some sarcomas and an environmental factor, namely, arthropod vectors.

During the period from September 1965 until December 1967, forty sarcomas of the soft tissues (site No. 197)[1] were received in the Department of Pathology of the Faculty of Medicine of the University of Kabul. Of the malignant neoplasms received during this period, this site ranked third (after skin and lymphomas), and accounted for 8·0 per cent of all cancers—7·0 per cent in males and 10·1 per cent in females. Of the forty tumours, twenty-three were in males and seventeen in females. Fig. 1 shows the age distribution for thirty-nine of these tumours. The average age of the males was 36 years, and the range was 6–75. The average age of the females was 37, and the range was 4–60. The incidence was highest between the ages of 36 and 45.

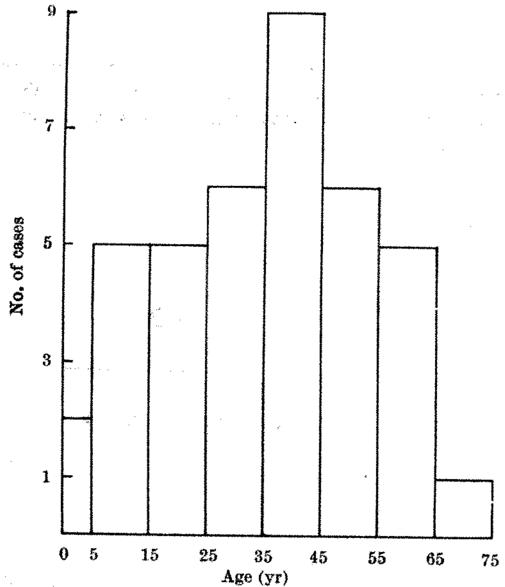

Fig. 1. Age distribution of sarcomas in Afghanistan.

Table 1. DISTRIBUTION OF SITES OF SOFT TISSUE SARCOMAS

Site	Head	Trunk	Upper limb	Lower limb
ICD No.	197.0	197.1	197.2	197.3
Males	3	4	2	14
Females	2	7	1	7
Total	5	11	3	21
Percentage	12·5	27·5	7·5	52·5

Table 2. DISTRIBUTION OF SOFT TISSUE SARCOMAS BY HISTOLOGICAL TYPE

Histological type	Fibrosarcoma	Rhabdomyosarcoma	Liposarcoma	Leiomyosarcoma	Small cell sarcoma	Haemangiosarcoma	Myxosarcoma	Unclassified
Males	9	1	1	2	3	–	2	5
Females	6	2	1	1	2	2	1	2
Total	15	3	2	3	5	2	3	7
Percentage	37·5	7·5	5·0	7·5	12·5	5·0	7·5	17·5

Table 1 shows the distribution of the sites of the sarcomas. More than 50 per cent were on the lower extremities, and almost half of these were on the thigh (ten cases). Table 2 shows the histological types of the tumours. Fibrosarcomas accounted for almost 40 per cent. Liposarcomas were rare compared with American and European series of tumours[2,3].

Undoubtedly, the relatively large proportion of soft tissue sarcomas in this series was influenced by the ease of resection and the obvious disfigurement caused by tumours at this site compared with deeper malignancies. The comparative youthfulness of the population in Afghanistan is another factor which might explain a high proportion of soft tissue tumours. Data provided by the National Malaria Eradication Project in Afghanistan showed that 52 per cent of the rural population were under 15 years of age. In the series which I studied, almost 50 per cent of the patients were less than 35 years old.

The aetiology of neoplasms of the soft tissues is unknown, although trauma is sometimes implicated. The connective tissues are usually protected from the environmental influences that affect the skin and other epithelial surfaces, for example, solar radiation, chemical agents, irritating foods and smoke. The subepidermal connective tissues, however, are particularly exposed to arthropods which pierce the epidermis.

The transmission of a variety of infectious diseases—viral, bacterial and protozoal—by arthropods is well known, and these animals have also been associated with the transmission of neoplastic diseases. Suspensions of adult and larval beetles administered orally or intraabdominally have produced leucosis in fowls[4]. The hamster reticulum cell sarcoma, *TM*, has been transmitted by the mosquito, *Aedes aegypti* (L), by a transfer of tumour cells. The cells remained viable within the vector for up to 8 h after ingestion[5]. The Shope fibroma virus can be transmitted by the bites of fleas and mosquitoes, causing neoplasms in the hosts, and may remain active in the vector for several weeks[6]. Squirrel fibroma virus can be transmitted by blood-sucking vectors, which remain infective for at least 16 days[6]. The Yaba monkey virus, which produces benign histiocytomas, is also thought to be transmitted in nature by blood-sucking arthropod vectors[6].

The experimental subcutaneous administration of tumour-inducing agents, both viral[7] and chemical[8], often leads to the development of sarcomas at the sites of inoculation.

The distribution of bites from crawling arthropods, for example, fleas, ticks and bedbugs, is similar to the distribution of our soft tissue sarcomas, that is, they are most abundant on the lower extremities and rarely found on the palms or soles.

The almost equal occurrence of the tumours in males and females may indicate an equal risk of exposure. Contact with vector-borne carcinogenic agents could begin very early in life and may thus account for the lower average age incidence for soft tissue sarcomas compared with other types of cancers. Viral carcinogenesis is more easily produced experimentally in young than in older animals[9].

The penetrating part of an insect is most likely to encounter the more superficial and abundant fibrous tissue of the dermis than the deeper fat and skeletal muscle or the comparatively sparse smooth muscle. This might explain why fibrosarcomas are most prevalent. Thus there is good reason for further examination of the hypothesis that soft tissue sarcomas may be caused by carcinogenic agents introduced through the skin by arthropod vectors.

PHYSIOLOGY

Time Relationships of Spermatozoon Penetration into the Egg of the Rhesus Monkey

IN some mammalian species, spermatozoa must be exposed to the female reproductive tract for some time before they acquire the ability to penetrate the egg[1,2]. During this time the spermatozoa are thought to undergo an essential physiological change—capacitation[3]—which enables them to pass through the mass of cumulus cells surrounding the recently ovulated egg, and then to penetrate the zona pellucida[4]. It is possible that capacitation is an essential prerequisite for fertilization in all mammals, but there is no direct evidence that capacitation occurs in the human or any sub-human primate.

In the species investigated so far, the need for capacitation has been established by a variety of experimental techniques, all of which depended on a detailed examination of the time relationship between insemination and the penetration of the spermatozoon[5]. We have been able to study the time relationships of spermatozoon penetration in the rhesus monkey.

Thirty observations were made on twenty-eight mature rhesus monkeys subjected to laparotomy between menstrual days 11 and 15. The monkeys all showed an established menstrual periodicity, and a deliberate attempt was made to synchronize the laparotomies with the time of expected ovulation in each monkey. At laparotomy, seventeen monkeys had ovulated and in the others the ovaries were in a pre-ovulatory condition. A suspension of epididymal spermatozoa was injected into the uterine lumen of the monkeys that had ovulated, and they were then maintained under surgical anaesthesia for about 6 h. During this time, their body temperature was maintained by using a heated blanket, and the initial pentobarbitone sodium ('Nembutal', Abbott Laboratories, Ltd.) anaesthesia, which had been adequate for the laparotomy, was supplemented with phencyclidine hydrochloride ('Sernylan', Parke Davis and Co.).

The eleven sperm suspensions for insemination were obtained from six normal, fully mature males that were being killed or castrated for other experiments. The contents of a single cauda epididymis, and as much of the vas deferens as was attached to it, were expressed into 2·5 ml. of medium *TC* 199. The resulting suspension was immediately inseminated into the uterus. Approximately 10^8 vigorously motile spermatozoa were inseminated in $<0·4$ ml. of medium.

Between 5·5 h and 6·5 h after insemination the original laparotomy wound was reopened so that the fallopian tubes could be flushed with physiological saline. The flushes were carefully examined for the presence of eggs and spermatozoa.

A total of nine one-celled eggs was recovered from the seventeen monkeys inseminated. All the eggs were naked and one was completely degenerate. Six eggs had not been penetrated by a spermatozoon although three had spermatozoa embedded in their zonae pellucidae. The numbers of embedded spermatozoa were four and twenty-six on two seemingly normal eggs, and six on the wholly degenerate egg. When the five, apparently normal, one-celled eggs were examined after fixation and staining[5] they were all found to contain a first polar body and their chromosomes were at the second meiotic metaphase.

Three eggs had been penetrated by spermatozoa. One egg was at the pro-nuclear stage and showed two well formed pro-nuclei (Fig. 1*a*), a first and second polar body and one spermatozoon embedded in the zona pellucida. The tail of the penetrating spermatozoon could be identified in the vitellus. This egg was recovered 6 h after insemination and was examined within 20 min of recovery. The other penetrated eggs both showed a swollen spermatozoon head (Fig. 1*b*) and an associated tail lying within the vitellus. A first polar body was present in each case and one and two spermatozoa, respectively, were embedded in the zonae. These eggs were recovered 6·5 h after insemination and examined within 20 min; in one egg the chromosomes were still at the second meiotic metaphase, whereas those of the other egg were at anaphase.

Spermatozoa were only detected in three flushes from the fallopian tube, and it was estimated that a total of <50 sperm were present in each of them. Thus, although a large number of spermatozoa had been inseminated directly into the uterus, the number recovered from the fallopian tube was similar to that observed after natural mating (unpublished work of Kelly and Marston).

It is not yet possible to determine the exact time of ovulation in the naturally cyclic rhesus monkey. In this study, it was not feasible to remove the ovaries that had ovulated so as to determine the morphological age of their corpora lutea. Thus the actual post-ovulatory age of the eggs we recovered cannot be estimated. Some of them may have reached the end of their fertilizable life

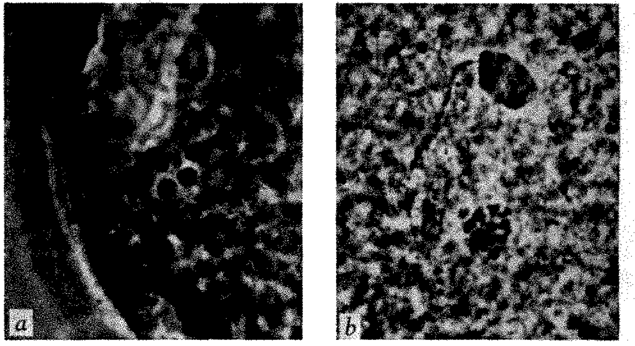

Fig. 1. Rhesus monkey egg after fixation and staining. *a*, Male pro-nucleus; *b*, swollen spermatozoon head and part of second meiotic anaphase figure.

before they were exposed to spermatozoa. The fact that three out of the nine eggs which we recovered had been penetrated suggests that, if capacitation is essential for spermatozoon penetration in the rhesus monkey, it must be completed within 6 h of insemination. By comparison with the rate of development in other mammals, it is possible that the pro-nuclear egg was actually recovered about 2–3 h after penetration. If this estimate is accepted, the process of capacitation may be completed within 3–4 h.

Experimental proof that capacitation is essential in the rhesus monkey can be obtained by showing that eggs are more rapidly penetrated by spermatozoa that have already undergone preliminary incubation in the female reproductive tract. Because our results suggest that the interval between insemination with epididymal spermatozoa and penetration of the egg is very short, it may not be practicable to show the superiority of supposedly capacitated spermatozoa over epididymal spermatozoa. Should this be the case, the need for capacitation in the rhesus monkey can only be inferred from indirect evidence: for example, by successful *in vitro* fertilization of monkey eggs with spermatozoa previously incubated in the female reproductive tract, and complete failure of *in vitro* fertilization with epididymal spermatozoa.

Relation of Epithelial Ion Transport to Corneal Thickness and Hydration

THE control of corneal thickness is a complex process involving the chemistry of the stromal tissue and the barrier properties of the two bounding membranes. Fluid dynamics are intimately involved, for corneal thickness is linearly related to hydration[1], which in turn is affected by ion transport. Also, it was shown recently that in the rabbit cornea the epithelium is the source of an active sodium transport system, and the endothelium shows only a passive behaviour in relation to the passage of ions[2].

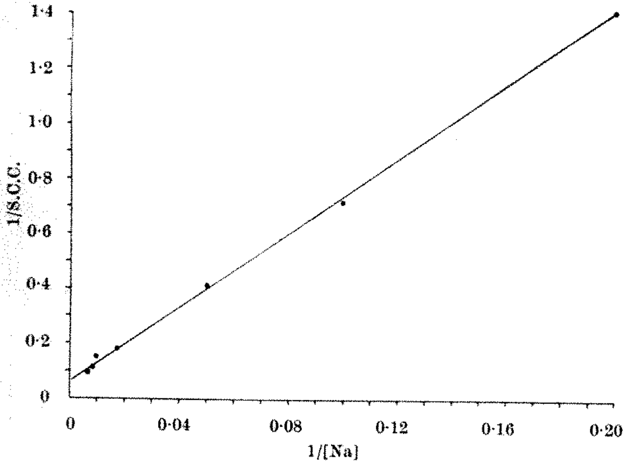

Fig. 1. Lineweaver–Burke type plot of short-circuit current (S.C.C.) against sodium concentrations in the fluid bathing the epithelial surface of the rabbit cornea.

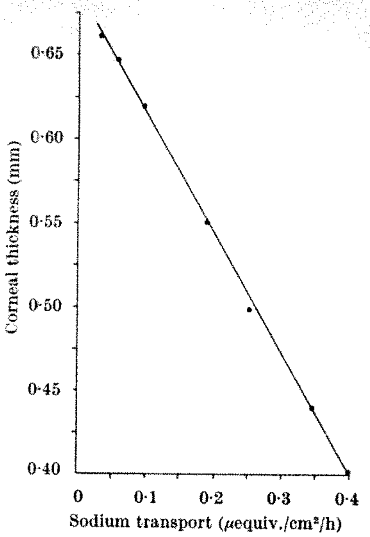

Fig. 2. The stable corneal thickness (mm) at each epithelial sodium concentration is plotted against the stable short-circuit current (in µequiv./cm²/h) at that sodium concentration.

To investigate the effect of the sodium transport system on corneal thickness and hydration, an external voltage was applied through the cornea in opposition to the standing potential (endothelium normally positive); the resultant increase in corneal thickness was proportional to the applied voltage[3]. It was reasoned that if the applied voltage controlled the active sodium transport, the variations in corneal thickness resulted from different rates of sodium transfer into the stroma. Correlated with the increases in thickness, decreases in the sodium concentration of the stroma were found; but no effect on other ions such as K^+ or Cl^- was seen.

Our experiments were made on isolated corneas mounted in chambers either for the measurement of electrical activity[4] or corneal thickness[3] (using a Haag–Streit slit lamp as modified by Maurice and Giardini[5]). Using Krebs–Ringer bicarbonate to bathe the cornea, the sodium concentration of the solution bathing the epithelial surface was decreased while the total chloride concentration and osmolarity of the solution were kept constant with the addition of choline chloride. The sodium-ion concentrations used to bathe the epithelial surface were 143, 118, 100, 60, 20, 10 and 5 mM, while the endothelial surface was bathed in 118 mM sodium throughout the experiment.

When the sodium concentration of the epithelial bathing solution was decreased, the short-circuit current, which indicates the rate of sodium transport, also decreased. When epithelial sodium concentration was plotted against the stable short-circuit current obtained with each of the various concentrations of bathing solution, a saturation-type curve was obtained. Fig. 1 shows the straight-line relationship seen in double-reciprocal plottings.

Corneal thickness was also seen to increase as the epithelial sodium concentration was decreased. When the solution bathing the epithelium was changed to contain less sodium, there was an increase in thickness dependent on the difference in sodium concentration. At all concentrations there was a stabilization of thickness after 80–100 min. If each stable thickness is plotted against the stable short-circuit current (converted to µequiv./cm²/h) at the particular epithelial sodium concentration, a straight-line relationship is obtained (Fig. 2).

In contrast, when the solution bathing the epithelium was maintained at 143 mM sodium and the sodium concentration of the endothelial solution was varied, the short-circuit current remained virtually unaltered. The rate of sodium transport was initially stimulated after these changes, but then stabilized at the original value.

Corneal thickness also showed little change when the endothelium was bathed in solutions of differing sodium concentrations.

These experiments reveal a direct relationship between the rate of transport of sodium ions and corneal thickness: as the rate of sodium transport decreases, corneal thickness increases. It was suggested from the previous work involving the use of applied voltages[3] that the rate of transport of sodium ions controls the sodium content of the stroma (which is primarily an anionic mucopolysaccharide) and in this way exerts a control on corneal hydration. The results reported here show that such a relationship between sodium ion transport and corneal hydration exists even without the application of extraneous (for example, electrical) forces. The transport–hydration relationship is physiologically fundamental to the control of corneal hydration and thickness. These findings also substantiate the role of the epithelium in the maintenance of corneal thickness.

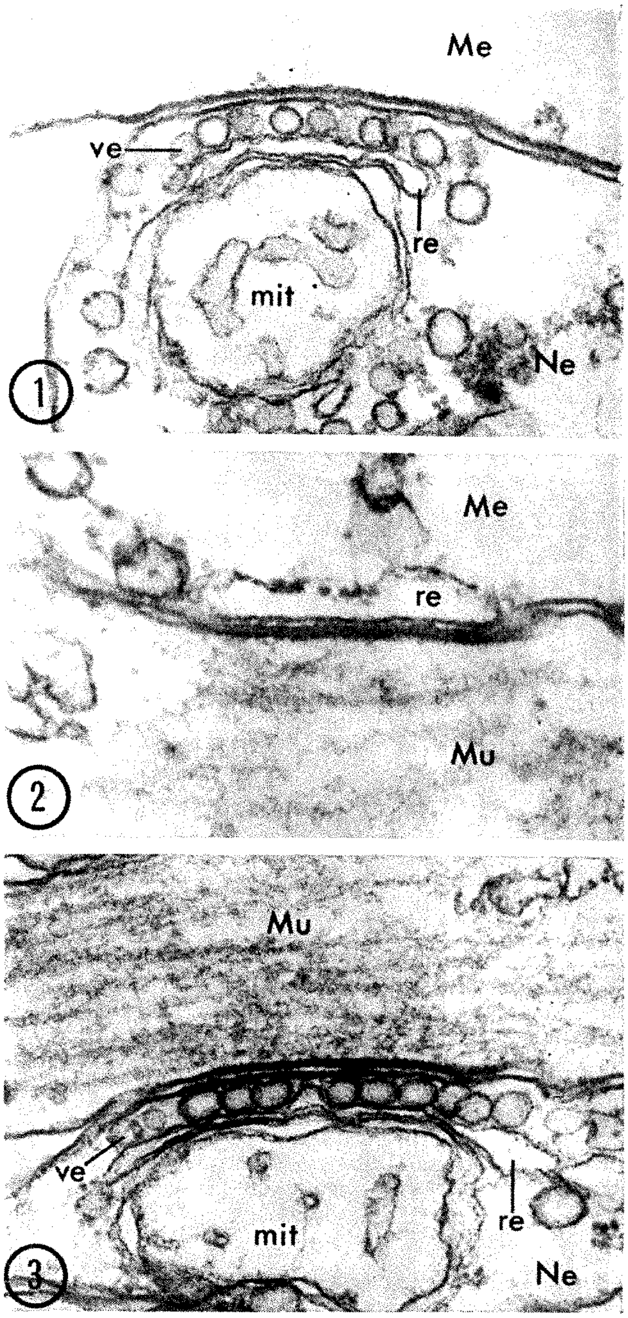
Specialized Connexions between Nerve Cells and Mesenchymal Cells in Ctenophores

THE mesogloea in ctenophores, as in certain coelenterates[1,2], is essentially a third cell layer containing muscle cells, nerve cells and so-called "amoeboid" cells[3,4]. Our unpublished studies on *Beroe* suggest that the "amoeboid" cells do indeed undergo a migratory phase during regeneration, but that there is no evidence of migration in the normal animal. Histological preparations show the cells with very long, thin processes connected together in the form of a net. We prefer to call them "mesenchymal" cells. We now have evidence from electron microscopy of specialized junctions between these mesenchymal cells and neighbouring muscle and nerve cells in *Beroe forskälii* and *B. ovata*.

At the neuro-mesenchymal cell junction the membranes are in close contact—separated by a gap of 130–150 Å—and show an obvious, densely staining thickening (Fig. 1). The nervous side of the junction is characterized by a row of vesicles tightly packed between the cell membrane and a sac of smooth endoplasmic reticulum, itself flattened against a single, huge mitochondrion (Fig. 1). The diameter of the vesicles ranges from 300 to 900 Å, with an average of 660 Å, which slightly exceeds the average size of "synaptic vesicles" of higher animals. After osmic fixation followed by block-staining with phosphotungstic acid (PTA) and section-staining with uranyl acetate and lead citrate, the vesicles look clear or are unevenly filled with a grey, amorphous mass. After fixation with glutaraldehyde, however, most of them show an electron-dense core of variable diameter.

Ultrastructural specializations such as those just described are also found at interneural, neuro-muscular (Fig. 3), neuro-glandular and neuro-sensory junctions in Beroids, Cydippids and Lobates (my unpublished results) and they correspond in essential features to the structures earlier described by Horridge[5,6] as synapses. If it is correct to regard them as such (and we assume that it is), it seems that the junctions between nerve cells and mesenchymal cells are also synapses, which implies that mesenchymal cells are effectors. It is noteworthy that mesenchymal cells receive large numbers of such synapses, in some cases receiving more than adjacent muscle cells. A single neurite may make synaptic connexions with both muscle and mesenchymal cells, which suggests that the two effectors could be excited at the same time.

In the absence of physiological evidence it would be inappropriate to speculate about the spread of excitation within or beyond the mesenchymal cell, or about possible effector action resulting from such excitation. It is of



Figs. 1–3. Electron micrographs from tangential sections of *Beroe forskälii* below the lip. Tissue fixed with OsO_4, buffered according to the method of Palade; embedded in 'Epon'; block stained by PTA; sections stained with uranyl acetate followed by lead citrate. 1, Neuro-mesenchymal junction (×59,000). 2, Junction between a mesenchymal cell and a muscular fibre (×82,000). 3, Neuromuscular junction (×59,000). *Me*, Mesenchymal cell; *mit*, mitochondrion; *Mu*, muscle cell; *Ne*, neurite; *re*, endoplasmic reticulum; *ve*, synaptic vesicles.

interest that specialized junctions of a distinct type occur between mesenchymal cells and muscle cells (Fig. 2) and between the processes of contiguous mesenchymal cells. These junctions show thickening and close approximation of the membranes (Fig. 2), but there is no accumulation of vesicles in the vicinity and the configuration is thus a symmetrical one. In junctions between mesenchymal cells and muscle cells a sac of endoplasmic reticulum does occur within the mesenchymal cell in direct apposition to the plasma membrane (Fig. 2). There is no evidence of membrane fusion and the junctions cannot be regarded as a type of "nexus"[7]. This does not, however, preclude the possibility that the junctions are somehow involved in information transfer between the cells in question.

From the point of view of comparative histology, it is instructive to align these observations of connexions between mesenchymal cells and nerve cells and between mesenchymal cells and muscle cells with evidence of similar connexions involving glio-interstitial cells in molluscs[8] and interstitial cells in rodents[9] and man[10].

Prostaglandins and Toad Spinal Cord Responses

PROSTAGLANDINS have a wide distribution in the vertebrate body and have been shown to be pharmacologically active on many types of vertebrate tissues. Evidence that these compounds have a neurohumoral role is suggested by several findings. Prostaglandins are widely distributed in the central nervous system[1], and in the rat cerebral cortex they are localized in synaptic vesicles[2]. They are released from the feline cortex[3] and possibly cerebellum and ventricles[4,5]. In addition, prostaglandins have effects on the central nervous system of cats and chickens[6,7]. We decided to investigate the effects of prostaglandins on the isolated toad spinal cord because the preparation is convenient for studying direct actions of drugs on a neuronal pool. Furthermore, prostaglandins are released from the frog spinal cord on stimulation of the hind limbs[8], suggesting that they are involved in synaptic transmission in amphibians.

Spinal cords of the toad *Bufo marinus* were isolated, hemisected and perfused with oxygenated amphibian Ringer solution. Experiments were performed during the Australian summer. The methods have been described in detail elsewhere[9,10]. The eighth dorsal root was stimulated every 10 s and a.c. or d.c. recordings were made from the ninth dorsal and ventral roots using Ag/AgCl electrodes. A d.c. preamplifier and 'Grass Polygraph' were used to record changes in potential level. Prostaglandins PGE_1, $PGF_{1\alpha}$ and $PGF_{2\alpha}$ (supplied by Dr J. E. Pike) were prepared as 10 mg/ml. solutions in 95 per cent ethanol. Stoichiometric conversion to the sodium salt was effected by adding 0·9 ml. of a 0·2 mg/ml. solution of sodium carbonate for each 1 mg of prostaglandin. Immediately before application the stock solutions were diluted to an appropriate concentration with amphibian Ringer solution. L-Glutamic acid was applied regularly to the preparation in order to assess its level of excitability.

The three prostaglandins, PGE_1, $PGF_{1\alpha}$ and $PGF_{2\alpha}$, all produced distinct changes in reflexes and polarization level when perfused over the toad spinal cord for periods of 0·5–2 min. Simultaneous d.c. records from dorsal and ventral roots were comparable except that drug-induced effects recorded from the dorsal root were more pronounced than those from the ventral root.

Typically, the prostaglandins caused a slowly developing, long-lasting depolarization of both dorsal and ventral roots. During the application of PGE_1, this was frequently preceded by a hyperpolarization of both roots. This is illustrated in Fig. 1*A*. Two minutes before the application of PGE_1, the spinal cord was perfused for 30 s with L-glutamic acid (5×10^{-5} g/ml.) which induced a rapid depolarization with a simultaneous reduction in size of the dorsal and ventral root potentials. Recovery was complete within 1 min of termination of the glutamate application. PGE_1 (5×10^{-5} g/ml.) caused a hyperpolarization during its 50 s application, followed by a depolarization which lasted for several minutes. The dorsal root polarization level had not reached control value 20 min after the application. During the hyperpolarizing phase of the response, polysynaptic reflex discharges in the ventral root were markedly reduced. Tracings *B* and *C* in Fig. 1 were recorded from the same preparation. $PGF_{1\alpha}$ and $PGF_{2\alpha}$ induced a slowly developing and long-lasting depolarization which began during the application.

PGE_1 had the most pronounced effects, usually causing a greater depolarization than L-glutamate applied in the same concentration. $PGF_{1\alpha}$ was usually more potent than $PGF_{2\alpha}$. Desensitization occurred with repeated applications. Thus, although the first application of a prostaglandin always had a significant effect, a second or third application a few minutes afterwards had little or no effect. On washing for 0·5–1 h, the prostaglandin again had a significant effect.

The results of this investigation, together with those of Ramwell *et al.*[8], suggest that prostaglandins have a

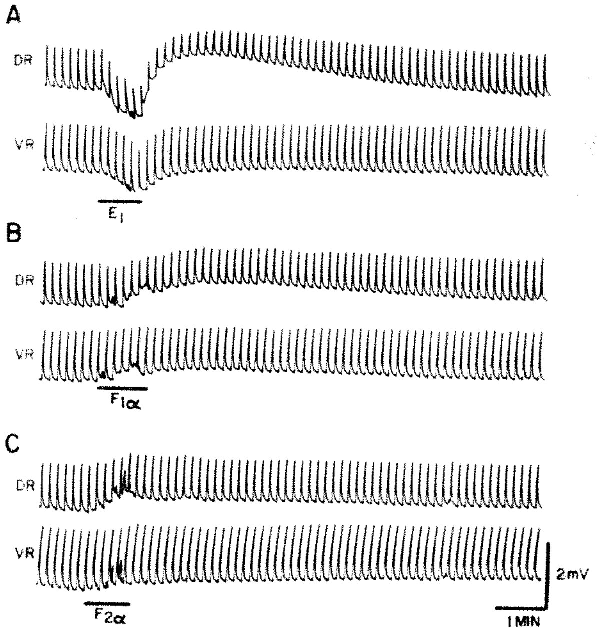

Fig. 1. d.c. Recording (negativity upwards) from dorsal and ventral roots of isolated hemisected toad spinal cord. *A*, *B* and *C* illustrate effects of three different prostaglandins on the same preparation, each applied in a concentration of 5×10^{-5} g/ml. Each pair of tracings represents simultaneous recordings from the ninth dorsal and ventral roots. The eighth dorsal root was stimulated at intervals of 10 s. Temperature was maintained constant at 20° C.

synaptic role in the amphibian spinal cord, but it is difficult to speculate on their mechanism of action. The extremely slow rate of recovery (their effects sometimes last for 0·5 h or more) may mean that they are not transmitters but that they affect the release of transmitter, as suggested by Ramwell *et al.*[8].

Evidence favouring the Existence of a Single Adrenergic Receptor

THE fact that adrenaline can act differently in various organs has often been explained by assuming that there are different kinds of receptors[1]. A simpler explanation of these differences in adrenaline action is that a single receptor, influenced in different ways by the different metabolic milieu in various organs, is sufficient to interpret all kinds of adrenaline effects. If this assumption is correct, the well defined receptor quality of the adrenaline effect, as tested by the effectiveness of different types of receptor blocking agents, can be transformed into another receptor quality in one organ, by changing its metabolic milieu.

This hypothesis is supported by the fact that the positive inotropic and chronotropic effects of adrenaline can be blocked by the alpha blocking agent ergotamine in the isolated heart of a frog[2], although myocardial effects of adrenaline in mammals are usually considered to be specifically connected with beta receptors[1]. If this difference is caused by the *a priori* lower metabolic rate of the frog heart, then increasing the metabolic level of the frog myocardium may result in the transformation of the quality of the adrenaline effect from alpha to beta. On this assumption, by lowering the metabolic rate of the mammalian heart, the adrenaline effect must lose its beta quality.

To test the validity of this assumption we altered the metabolic rate of both isolated amphibian and mammalian hearts by increasing or decreasing the temperature of the perfusion fluid. Frog hearts were isolated according to Straub. Rat hearts were isolated according to Langendorff and perfused at 38° C with Locke solution, containing 10 per cent of washed canine red blood cells. Adrenaline sensitivity (effective threshold dose for positive inotropic and chronotropic effects) was repeatedly determined in each preparation. To determine the adrenergic receptor quality of the myocardium, 3×10^{-8}–2×10^{-7} M phentolamine ('Regitin', Ciba) was used as an alpha blocking agent, and 2–4×10^{-8} M pronethalol ('Alderlin', ICI) or 1–3×10^{-8} M propranolol ('Inderal', ICI) was applied as beta receptor blocking agents. The blocking capacity was estimated on the basis of the decrease in adrenaline sensitivity after the administration of the blocking agent. Contractions of the heart were recorded by an isotonic lever.

The capacity of an alpha blocking agent to block the adrenaline effect in the frog heart[2] was confirmed in these experiments, and 3×10^{-8}–2×10^{-7} M of phentolamine was effective in blocking the adrenaline effect in the winter frog heart; that is, it decreased adrenaline sensitivity in twelve out of thirteen experiments at room temperature. When the metabolic rate of the winter frog heart was increased by raising the temperature to 30°–34° C, the blocking capacity of the same dose of phentolamine diminished, or disappeared completely, as illustrated by a typical experiment in Fig. 1. Adrenaline sensitivity of a winter frog heart was 0·0001 µg at 22° C (Fig. 1*A*). After 10 µg of phentolamine had been added, adrenaline sensitivity was decreased to 1 µg, that is, phentolamine produced a 10,000-fold blockade. At 32° C (Fig. 1*B*) adrenaline sensitivity of the same preparation was 0·001 µg. After the addition of 10 µg of phentolamine it remained unchanged, that is, the blocking capacity of phentolamine disappeared.

The blocking capacity of phentolamine, however, could not be observed at all either in the summer frog heart at room temperature or in the rat heart at 38° C, both preparations representing an *a priori* higher metabolic rate than in the winter frog heart. Decreasing the metabolic rate of the summer frog myocardium by cooling to 5°–10° C and by administering 10^{-7} M dinitrophenol resulted, however, in five out of six cases, in the re-establishment of the phentolamine blockade which was initially lacking. Thus the capacity of an alpha blocking agent to produce adrenergic blockade in the myocardium is apparent only at lower metabolic rates.

The opposite correlation was found when beta blocking agents were applied. Thus 2–4×10^{-8} M pronethalol, or 1–3×10^{-8} M propranolol, which could block the effect of adrenaline in both summer and winter frog hearts at room temperature (sixteen experiments), as well as in rat hearts at 38° C (six experiments), lost their blocking capacity when the temperature was lowered to 5°–10° C in the summer frog heart or to 27° C in the rat heart, that is, when the initially higher metabolic rates of these two preparations were lowered. This phenomenon is illustrated in Fig. 2. In a rat heart 10 µg of propranolol completely blocked the positive inotropic and chronotropic effects of 2 µg of noradrenaline at 38° C (Fig. 2*A*). At 27° C (Fig. 2*B*) the same dose of propranolol produced no blocking effect at all: 2 µg of noradrenaline had the same effect as before propranolol was added. When the perfusion fluid was reheated to 38° C (Fig. 2*C*) the blocking capacity of propranolol was re-established; once

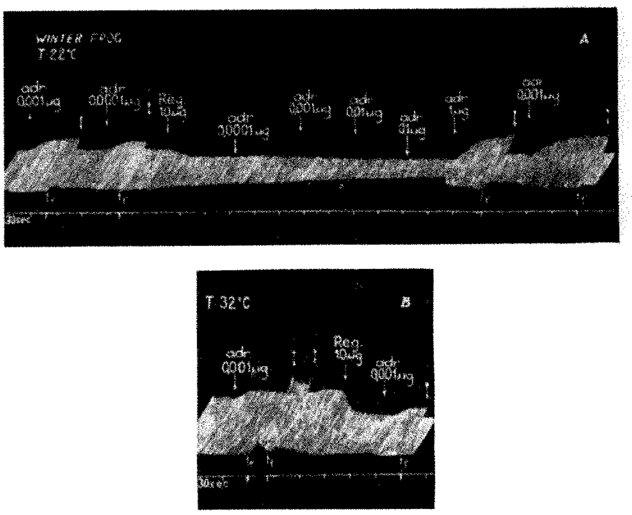

Fig. 1. Winter frog heart. Influence of change of temperature on the blockade of the adrenaline effect by 10 µg of phentolamine. Time signal: 30 s. ↓ designates washing out of substances. For explanation, see text.

again it completely blocked the effects of 2 µg of noradrenaline. Two minutes later, when propranolol had been washed out, 2 µg of noradrenaline was again effective.

When, on the other hand, the temperature was increased to 30°–34° C in the winter frog heart, the blocking capacity of the beta blocking agent pronethalol remained unchanged, or even increased in some cases, as compared with the diminishing or complete disappearance of the blockade produced by the alpha blocking agent phentolamine in the same experiments.

The principal trends induced by altering the metabolic milieu are summarized in Fig. 3. The degree of blocking capacity of the antagonists is expressed in all cases in terms of the log of the dose ratio, which is the ratio of effective threshold dose of adrenaline before and after blockade. When the temperature is lowered from 22°–24° C to 5°–10° C in the summer frog heart (Fig. 3*A*), the beta blocking capacity disappears, as shown by a significant decrease in the blockade, from $1{\cdot}95 \pm 0{\cdot}43$ to $0{\cdot}67 \pm 0{\cdot}39$ produced by pronethalol. In all cases, the dose of blocking agent remained unaltered in one and the same experiment. On the other hand, raising the temperature from the initial level to 30°–34° C (Fig. 3*B*) resulted in a decrease of the alpha blocking capacity, shown by a decrease in the blockade produced by phentolamine from $1{\cdot}18 \pm 0{\cdot}17$ to $0{\cdot}48 \pm 0{\cdot}13$.

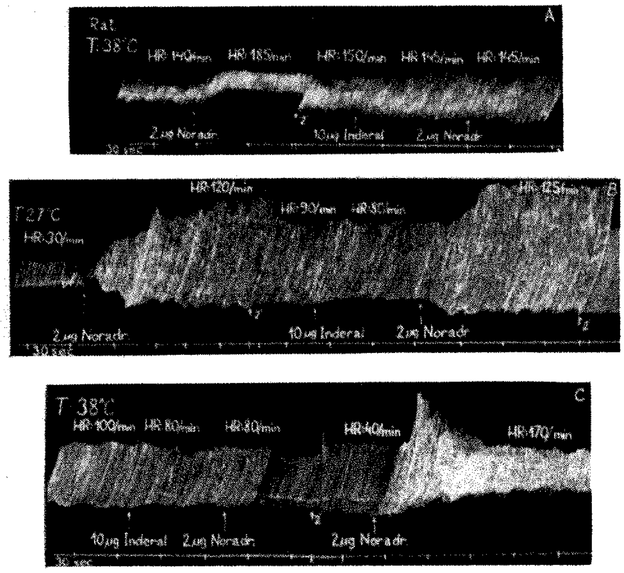

Fig. 2. Isolated rat heart. Influence of change of temperature on the blockade of the myocardial effects of noradrenaline by 5 µg of propranolol. Time signal: 30 s. HR, Heart rate. For explanation, see text.

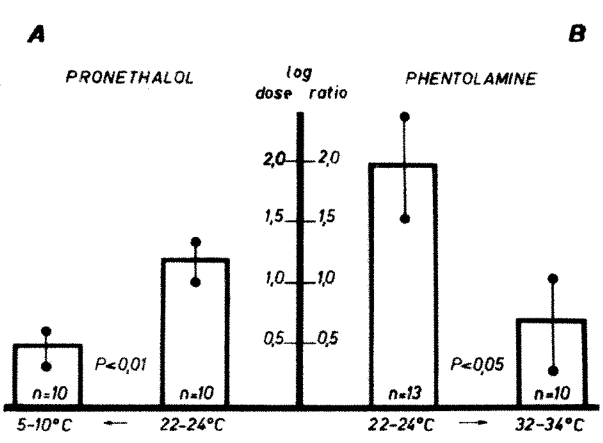

Fig. 3. *A*, Degree of blockade of adrenaline effect by $2\text{–}4 \times 10^{-8}$ M pronethalol at 22°–24° C and 5°–10° C in the summer frog heart. *B*, Degree of blockade of adrenaline effect by $3 \times 10^{-8}\text{–}2 \times 10^{-7}$ M phentolamine at 22°–24° C and 32°–34° C in the winter frog heart. Ordinate: log (dose ratio) of adrenaline sensitivity before and after blockade. *n*, Number of experiments; *P*, probability ratio. Vertical lines: standard error.

If these two trends are the results of different sensitivity of a single receptor, then there must be a state in which both types of blocking agents are equally and separately active; this was found in the case of the winter frog heart at 22°–24° C. This latter finding is incongruous with another possibility, that tissues can contain both alpha and beta receptors, with one predominating. If this were so, the greatest difference in the two kinds of blockades should have been found at room temperature, the temperatures at which frogs were previously kept and to which they had presumably become adapted. In this hypothetical case, only the combined administration of the two types of blocking agents could have produced an inhibitory effect instead of acting separately.

It can therefore be stated that the prerequisites for the existence of a metabolically influenced single adrenergic receptor—as far as myocardium is concerned—have been fulfilled in the present experiments.

GENERAL

Recognition of Syntactic Structure by Computer

The recent article concerning computer simulation[1] is refuted by its first sentence. As the first condition for an acceptable simulation of the way in which human beings recognize syntactic structure, the authors say "an analyser must not be dependent on looking up every word of an input sentence in a dictionary". To meet this condition a dictionary is used which contains information "only about those words with fixed syntactic functions and about suffixes". "With this dictionary alone, infinitely many English sentences can be analysed." Unfortunately, there are also "infinitely many" sentences which cannot be analysed in this way. The first sentence of the article is one such sentence.

This sentence is: "An essential part of the capacity to understand utterances lies in the ability to recognize syntactic structure". Any English-speaking reader can refute the article by playing the following simple game. First, rewrite the sentence keeping the pronouns, conjunctions and prepositions and substituting for other (non-fixed syntax) words an *X* plus the endings -s, -ed and -ing (if they appear). Second, the reader must try to replace *X*s by words which have a different syntactic function from the word in the original sentence. For example, the sentence is rewritten as "An *X* *X* of the *X* to *X* *X*s *X*s in the *X* to *X* *X* *X*". For the first two *X*s the noun–verb combination "actor knew" can be substituted for the adjective–noun combination "essential part". Whenever such a substitution can be made, the reader wins and the computer programme loses.

BOOK REVIEWS

HONOUR TO A PHYSICIST

Gustav Hertz in der Entwicklung der Modernen Physik

Festschrift zum 80 Geburtstag von Gustav Hertz am 22 Juli, 1967 (Abhandlungen der Deutschen Akademie der Wissenschaften zu Berlin—Klasse fur Mathematik, Physik und Technik, Jahrgang 1967, Nr 1) Pp 205 (Berlin Akademie-Verlag, 1967) n p

THIS is a "Festschrift" in the usual German style in honour of Gustav Hertz's eightieth birthday. It consists of a collection of specialized papers of high standard, but very heterogeneous, they are related in very varying degrees to Hertz's sphere of interest Only two short papers recall the main contributions of Hertz to atomic and nuclear physics, and draw a picture of his attractive personality Hertz won fame at an early stage of his career through his fundamental discovery, in collaboration with J Franck, of the excitation of quantal transitions in atoms by electron collisions a phenomenon that gave powerful support to the ideas just proposed by N Bohr Later he turned his attention to the processes of gas diffusion and developed a successful method of isotope separation based on these processes In the teaching and organization of physics in Germany he has been very influential, both before and after the Second World War; and his handling of the practical and human problems he had to face was characterized by the same common sense and directness of approach as his attitude towards the fundamental issues of science L ROSENFELD

ATMOSPHERE IN RUSSIA

Optical Instability of the Earth's Atmosphere

By N I Kucherov Translated from the Russian Pp viii+174 (Jerusalem Israel Program for Scientific Translations, London Macdonald—Oldbourne Press, 1966) 54s

THIS is a collection of papers, mainly the proceedings of a conference held at Kiev in 1962 (the Third All-Union Conference) It is unfortunate that such conference reports, and collections of papers in general, are presented with little or no connecting material In this case the topic is quite specific, and many of the papers are closely related there are twenty articles on the effect of the atmosphere on optical images obtained in astronomy, and it is easy to see how they could have been connected or even combined The advantages would be that a useful introduction to the whole subject would be created and that different approaches to the problems and comparable results would be brought together

First, a fair introductory chapter could be assembled from the various papers that establish the terminology, give physical explanations of the various phenomena, give fundamental theory, and give discussions of previous work The seven papers on image pulsation (position fluctuations observed with, for example, a 30 cm telescope) could easily be connected by a joint introductory and summarizing chapter Similarly, there are three papers in which optical instabilities are analysed in terms of meteorological phenomena this is an aspect of the subject in which progress has been difficult, and this could be emphasized by a brief general review of previous work It would be particularly interesting to have a comparative summary of the six papers which report on the magnitudes of the effects observed in various areas in tests of possible sites for new observatories The remaining four papers could not be combined quite so advantageously, although three of them are related to automatic observing. In addition, an index would have been useful

The experimental techniques described in some of the papers deserve special attention In a paper on "Pulsation of an Artificial Light Source in the Ground Layer" by V M Bovsheverov and others, there is an account of image pulsation observations made in known conditions, and resulting in a remarkably good verification of the theoretical treatment in terms of temperature and wind speed gradients O B Vasil'ev and V. S Sumin describe in detail their instruments for measuring image pulsation from photographic star trails, and it is clear that they have constructed a very successful machine Z N Kuteva and Yu A Sabinin describe a programmed automatic telescope which uses rotating transformers both for storing star co-ordinates and reading the position of the telescope, resulting in a simple and reliable installation

The topics covered in these papers receive considerable attention in the Soviet Union and this book is a useful progress report on this research R G BINGHAM

STATISTICAL PHYSICS

Statistical Physics

By A F Brown (Edinburgh University Publications—Science and Mathematical Texts, 7) Pp x+307 (Edinburgh Edinburgh University Press, 1968) 45s net

THIS book lies between an orthodox course on the properties of matter and a systematic treatment of statistical mechanics Professor Brown develops from first principles the concepts of probability distributions, and applies them to a selection of physical problems, mainly from the kinetic theory of gases and from solid state physics The general level is that appropriate to first-year university students of physics or chemistry Comprehensive coverage is not attempted and, in making the mathematics self-contained, many topics have had to be omitted There is, for example, no discussion of the various types of atomic interactions, of radiation, nor of Fermi and Bose statistics, even at a qualitative level Within the limits set by the author, the presentation is clear and straightforward, although more thermodynamics is assumed than is perhaps usual at a first year level

The first two chapters develop the elementary kinetic theory of gases Apart from misprints in equations (1 3 1) and (1 10 1) these should offer the student no difficulty, although I would have liked to see some mention of the distinction between averaging over particles and averaging over time The use of Clarendon type for the number density **n** seems rather arbitrary, because this is not done for other dimensional quantities

The theories of probability distributions and averaging in general are deferred to the third and fourth chapters, the latter also introducing the mean free path concept.

The fifth chapter contains as thorough a discussion of the Maxwell–Boltzmann distribution for gases as is possible at this level, later extended to more general systems. The sixth chapter contains a good short discussion of random walk and applications to diffusion problems The seventh chapter consists of statistical treatment of experimental results Again the presentation is clear, but this chapter is really a digression, and I feel it would be better moved to the end of the book In the eighth chapter the statistical concept of entropy is introduced For such an important topic it is surprising that this chapter should occupy only seven pages and be one of the only two in the book without problems or references

The ninth and tenth chapters contain various solid state topics, including melting, the Einstein specific heat model, order–disorder theory and diffusion processes in semiconductors The discussion here is lucid and well sustained. The final two chapters form essentially a statistical and mathematical appendix which might have been merged with the third chapter, although sections 12 1, 12 4 and 12 8 are so standard that their inclusion seems hard to justify

Misprints are remarkably few, and the price seems reasonable With the reservations mentioned, it should prove a useful first year book, although in subsequent editions some rearrangement of the chapters might be considered R COLLINS

MAGNETIC RESONANCE

Magnetic Resonance and Relaxation

Edited by R Blinc With the co-operation of D Hadzi and M Osredkar (Proceedings of the 15th Colloque Ampère, Ljubljana, 6–11 September 1966) Pp cv+1241 (Amsterdam North-Holland Publishing Company, 1967) 420*s*

As usual, the Colloque Ampère of September 1966 covered the whole broad spectrum of magnetic resonance and relaxation The proceedings consist of short contributed papers on rather specialized topics and in addition some invited longer papers often in the form of a concise review of a broader topic Much of the material of the short papers has since appeared in expanded form in the journals so that the value of the volume today lies largely in the review articles that it contains The subject matter for these longer papers (there are about thirty of them) ranges from molecular reorientation and nuclear relaxation in liquids to Jahn–Teller effects in solids and the Mossbauer emission from atoms in relaxing localized modes Their level is such that they can be readily understood by anyone with a background in magnetic resonance and serve in many cases as a good introduction to a given topic It would be difficult to find anyone in the field who did not find several of the articles of interest Personally, I found many of considerable interest, among them those dealing with nuclear acoustic resonance, nuclear resonance in superconductors, spin–spin relaxation, and on the mechanisms of dielectric relaxation

The price of the volume is such that few individuals will feel inclined to buy it, but any institute with an interest in magnetic resonance may well find it a worthwhile investment D. T EDMONDS

THEORETICAL CHEMISTRY

The Fundamentals of Theoretical Chemistry

Wave Mechanics Applied to the Study of Atoms and Molecules By Raymond Daudel Translated by R. E Watts Translation edited by J M Wilson Pp xx+211 (Oxford, London and New York Pergamon Press, 1968) 80*s*

THIS is an English translation of a French volume written in 1952 It is one of a series of three volumes by the same author, who is one of the leaders in French theoretical chemistry The first half of the book is devoted to a study of atoms, at a relatively simple level (but not for a complete beginner) The second half deals with molecules, concentrating chiefly on the method of molecular orbitals

It may well be asked whether the publication in 1968 of a book of this kind, written sixteen years ago, is justified Inevitably many new developments have taken place in these years, with the result that the volume has a rather "old-world" character Topics such as the Pekeris discussion of the helium atom, the Kolos–Roothaan work on molecular hydrogen, the Pariser–Parr approximation, and all mention of ligand-field theories, are missing The chief value of the book lies in the account—believed to be the only full account in any textbook—of Professor Daudel's concept of a loge This is a volume within which we have a fairly large probability of finding exactly one electron (or sometimes two, with opposed spins), and represents one of the best ways of localizing electrons in a physical picture

The translation is good, but the price of the book is ridiculous C A COULSON

AROUND LANGHOLM

The Geology of the Neighbourhood of Langholm

(Explanation of One-Inch Geological Sheet 11) By G I. Lumsden, W Tulloch, M F Howells and A Davies Palaeontology by R W Wilson, M A Calver and J D. D Smith Petrography by R W Elliot and M F Howells (Natural Environment Research Council–Institute of Geological Sciences Memoirs of the Geological Survey, Scotland) Pp viii+255+8 plates (Edinburgh and London HMSO, 1967) 52*s* 6*d* net

THE dust cover of this book has an attractive photograph of Langholm and its surrounding hills the blurb notes that the memoir traces the story of the deposition of the rocks from the oldest strata to the present day, refers to periods of major earth movement during which the rocks were thrown into great folds, and records at least four episodes of violent volcanic activity and two of the advance of great masses of ice And then

> "The Memoir contains much scientific detail about thousands [!] of outcrops, many boreholes and the more important natural sections, sedimentary structures and the petrology of selected strata and includes exhaustive lists of fossils"

from which the avid reader of Geological Survey memoirs will realize that the wrapping merely disguises the old familiar offering of painstaking, detailed work in which every outcrop appears to have been described, every fossil identified, and the petrography of each rock slice recorded

The six-inch geological maps of the area are already available, the one-inch is in the press Why then almost eighty pages of such detail as (page 33)

> "Green Cleuch is the stream which joins the Meikledale Burn on the east bank 450 yd upstream from Swingill A small asymmetrical anticline plunging west at 27 degrees is exposed about 210 yd upstream from the stream junction [37069536] The beds on the north limb are vertical and young north, while on the south limb the dip is south-south-west at 43 degrees Movement along the bedding has obviously taken place at this locality"

and (page 64)

> "An igneous intrusion is associated with the Enthorn Fault where it crosses the River Esk (p 204) near Glencartholm, 350 yd downstream from the mouth of the Hag Burn [37867897] Its outcrop in the Archer Beck, 400 yd W 43° S of Millstead [42008096]" etc

There are more than three hundred fossil localities pinpointed with such duplicated precision as (page 20)

> "Crue Gill, tributary of Wolfhope Burn draining the north-east slopes of Longgrain Head at head of stream 1600 yd S 63° W of Rigfoot [35769248] ?*M riccartonensis* Zone"

This kind of detail riddles the memoir and is precisely what geological maps, symbols and National Grid references were intended to obviate

Four geologists with supporting scientific staff have been engaged in this project on and off during the past sixteen years Their results are or will be embodied in six-inch sheets, one-inch map, memoir, scientific papers and sundry data including borehole records on open file So far as this consumer is concerned much of the detailed information in the memoir should have been restricted to the maps or put on open file Indeed, why not go one stage further and adopt the USGS custom of publishing a

12,000 word explanation of the geology of the area on a folding sheet containing the one-inch map? The need for some memoirs might then disappear, with resulting saving of effort and money

This preoccupation with what goes where and how should not obscure the fact that a useful survey has been made The work tends to confirm that the Southern Uplands consist of complex faulted monoclines Perhaps more importantly the memoir provides the first full description and classification of the Carboniferous rocks of the district G Y CRAIG

NOTODELPHYID DEVELOPMENT

Development and Systematics of Some Pacific Marine Symbiotic Copepods

A Study of the Biology of the Notodelphyidae, Associates of Ascidians By Patricia L Dudley Pp v+282 (Seattle and London University of Washington Press, 1966) 56s

ASCIDIANS provide a number of ecological niches for a great variety of invertebrate parasites and messmates Of the ascidicolous copepods the Notodelphyidae exhibit the greatest morphological diversity, many of the species are known only from adult females Although in 1892 Canu illustrated some developmental stages of five European species and succeeded in rearing some of their free-living copepodid stages, no complete life cycle of a notodelphyid was known In recent years the author has succeeded in culturing the free-living stages of all eight species, representing five genera, that occur in the Puget Sound region and has obtained from the hosts later commensal or parasitic copepodids to complete the life cycle of four species

Short sections on material and methods and on terminology follow the introduction, while collecting and culture data are given in the appendices Pre-eclosional development, eclosion of the nauplii and their escape from the host are described Post-eclosional development is considered under four main headings the nauplii, the copepodid stages, a comparison of the copepodids, and sexual dimorphism There are five naupliar stages in each of the seven commensal species and only four in the parasitic one The internal anatomy of the nauplii is described Development of the post-mandibular appendages proceeds gradually throughout the naupliar phase In these, and other yolky cyclopoid nauplii reared for comparison, the delicate transparent cuticle is never wholly in contact with these forming appendages and the exuviae therefore show little or no trace of these changes The author suggests that here a different mode of cuticle formation may be involved For each naupliar stage the superficial subexuvial structures are described as well as the exuvia In metal-contaminated sea water normal swimming movements and normal ecdysis may be arrested although differentiation of appendages and internal organs continues, in the parasitic species production of exuviae continued but the larvae were enclosed in two or even three skins

All eight species could be reared to the second copepodid, which is probably the invasive, stage, only in species of the genus *Doropygus* did any of these moult to the third copepodid stage A kind of metamorphosis occurs during the last naupliar stage, when copepodid features become more highly developed beneath the cuticle At the moult to the third copepodid a second metamorphosis occurs This third stage and subsequent stages are as useful in the taxonomy of the species as are the adults Sexual dimorphism is first apparent in the fifth copepodid stage in all the commensal species, in the highly modified parasitic species, it is first apparent in the fourth, and becomes marked in the fifth, stage The sixth stage is the adult for all the species and ecdysis ceases Since the females had been described in a recent work by Illg, only additional notes are given The much rarer males are fully described One species of *Doropygus* proves to have dimorphic males Non-swimming anamorphic males, differing only slightly from male fifth copepodids, are commonly found in ascidians The actively swimming metamorphic males were obtained direct from male fifth copepodids which were removed from the host and placed in culture dishes So far, only two metamorphic males have been found in ascidians

The relationship of the Notodelphyidae to other groups of copepods is discussed, utilizing first the adult characters then those of the developmental stages The naupliar characters of free-living copepods are enumerated, to show that there is a basic deviation in development between calanoids and cyclopoids, and to serve as a basis for comparison of notodelphyid nauplii with those of other commensal and parasitic forms Trends in reduction of mouthparts differ in the true poecilostomous cyclopoids like *Mytilicola* from those shown by Enterocolidae, Botryllophilidae and the aberrant parasitic notodelphyids These all show relationships with the gnathostomes

The book is well written and well arranged and will doubtless become the standard work on notodelphyid development The excellent line drawings are arranged as plates, labelled "Figure 1" to "Figure 51", inserted together with their legends between pages 164 and 269 There is no index, so the reader must rely on a short table of contents I GORDON

INTRODUCING BEHAVIOUR

An Introduction to Animal Behaviour

By Aubrey Manning (Contemporary Biology) Pp viii+208 (London Edward Arnold (Publishers), Ltd, 1967) 42s net, boards, 21s net, paper

THE study of behaviour has progressed far enough for the stage of pure description of behaviour patterns to be superseded by discussions of the facts by which the patterns can be explained, or for, at least, some sort of reasonable approach to a theoretical background to begin to be assembled Rightly, therefore, Dr Manning has not approached the subject from the standpoint of the biological function of particular patterns, like courtship, prey catching or the like, but reviews the principles on which behaviour is founded Not that natural selection is not one of these producing, as it does, biologically useful patterns, this is the other side of the coin, but an unusual coin, for its two sides are not starkly separated by a hard edge Nor is this a text in which the same behaviour in various groups is compared, although this evolutionary approach is one which has always commended itself to the zoologist as opposed to the psychologist The truth is that, apart from that derived from a few groups of closely allied species, the amount of comparative behavioural work is not very great It is striking that the examples of this approach are the same as would have been quoted in a book written ten years ago, there is no doubt that the immediately post-war work by the European behaviourists was classical in the sense that it will be quoted with advantage for a long time to come

In his preface, the author excuses the selection of topics explaining that the book was to be short and that he preferred to deal with those topics which he felt to be important This surely makes for a lively, interesting book instead of one recounting, dryly and dutifully, subjects which are dull to the author This book is stimulating and very thoroughly does what the author set out to do, that is, to introduce the subject by reviewing the current interests of ethologists and others

Manning's chosen subjects are "Reflexes and Complex Behaviour", "Development of Behaviour", "External Stimuli", "Motivation", "Conflict Behaviour", "Hormones and Behaviour" and "Evolution and Learning" It is plain from this list of chapter headings that Manning reflects the investigations of many workers today in the physiology of behaviour and draws, in his own researches, on the genetical approach That the genes act on behaviour by changes mainly in physiology rather than in detectable macrostructure is nowadays evident, although the difficulties of genetical analysis in this field are very great

Manning's selection of work ranges widely, as is made evident by almost 300 references listed at the end of the text, but sensibly, wherever possible, he has cited reviews rather than original papers For the student reader, at whom the book is directed, this is the only practical approach The book is well produced and illustrated, there is no reason why it should not be highly appreciated by its readers J D. CARTHY

BOOK OF A MONKEY

Biology of the Howler Monkey (*Alouatta caraya*)

(Bibliotheca Primatologica, No. 7) Edited by Manuel Rene Malinow Pp viii+232 (Basle and New York S Karger, 1968) 48 Sw francs, 88*s* ; $11 50

PEDANTRY is a tiresome stick with which to belabour anybody but, in the name of Linnaeus, a sensitive reviewer must protest against the nomenclatural error in the title of the book *Alouatta*, the howler monkey, is a genus containing five good species only one of which, *A. caraya*, is dealt with in this book that purports to be a "Biology of the Howler Monkey" This is most misleading

It is also somewhat misleading to call this book a "Biology" which suggests a comprehensive, systematic approach that this eclectic compilation does not attempt to achieve. Ecology, evolution, systematics and free-ranging behaviour are either wholly omitted or, at best, perfunctorily acknowledged One curious omission is any reference to the voice of the black howler monkey or to its extraordinary vocal anatomy, this is rather like making an apple pie without apples.

There are, however, a number of extremely useful independent chapters on the anatomy and pathology of this so far little known species Particularly valuable are chapters on growth, age determination and pre and post-natal development, some of which have been published elsewhere Malinow's contribution to the natural history of arterial disease in free-ranging primates is of great interest, especially his observations relating to the reduced incidence of atherosclerosis in pregnant animals Grand's analysis of the functional anatomy of the upper limb is a careful and thoughtful contribution

The good old-fashioned one-man monograph with its synthetic treatment of data and its total biological approach is becoming a rarity these days Its place in scientific literature has been taken by the multi-authored volume which neither covers the field nor attempts to present an integrated, balanced picture of the central organism Only too frequently, as in the present instance, many of the articles are reprints One questions the value of such compilations particularly at £4 8*s* and in paperback form JOHN NAPIER

CONTROLLING SPEECH

Research in Verbal Behaviour and Some Neurophysiological Implications

Edited by Kurt Salzinger and Susanne Salzinger. Pp xvii+510 (New York Academic Press, Inc ; London, Academic Press, Inc (London), Ltd , 1967) 88*s*

WHAT goes on in the brain when we speak, or are otherwise linguistically active, is a tantalizing problem, for it bears directly on the biological status and prospects of Man But many approaches and methods commonplace in the study of other "higher" functions of the brain are unavailable in the case of language. Animals do not speak and we cannot systematically cut away parts of the human brain to find out the effects on language Instead we have to wait on "Nature's experiments" and her techniques are casual and unsuited to scientific convenience. Opportunities of stimulating and recording from the intact brain while it is occupied in linguistic activity are scarce, and the results so far unrevealing Starting from the other end, analyses of language itself on its own terms, and of the human behaviour involved in its use, have made some progress But as they become more sophisticated their conclusions all too often seem remote from the concepts of contemporary neurophysiology Modern grammatical theory, for instance, is replete with patterned structures of one kind and another Which of these should we pick on to lay alongside any observable pattern of functioning in the nervous system ?

It is very tempting to try to bridge a gap such as this, and not always unprofitable even when there is more make-believe than masonry in the construction. As it happened, however, this symposium stopped short of any actual bridge building and devoted itself largely to laying down approach roads The first section, "Verbal Behaviour Facts and Theories", which occupies half the book, comprises a good deal of material familiar to readers of previous psycholinguistic symposia, though it breaks fresh ground in places Even here, however, as for example in Staats's paper on emotions and images in language, in the two essays by Lambert and by Fillenbaum on verbal satiation or in Lambert and Preston's note on the bilingual's two languages, there is evidence of undue anxiety to force the material into preconceived theoretical or methodological moulds But there are also examples, such as Starkweather's paper on the vocal characteristics of depressed patients, of a more straightforwardly empirical approach

The second section, "Verbal Behaviour as a Function of the State of the Organism", concentrates very largely on the effects of drugs on verbal and vocal behaviour, and Waskow contributes a general summary of work in this field to date Perhaps naturally, there has been much concentration of drugs in current psychiatric vogue, notably LSD, chlorpromazine and amphetamine. The outcome of this work is on the whole disappointing, but new drugs and new knowledge about their biochemical modes, and anatomical sites, of action are coming along fast, and thoughtful use of these may go far to establish some of the neural correlates of speech behaviour

The last section, "Neurophysiological Bases of Verbal Behaviour", in which the innocent reader might expect to find some evidence of bridge building on the other side of the chasm, is short and frankly disappointing. It contains four essays, by Luria (who was unfortunately unable to be present at the symposium), Geschwind, Davis Howes and Chase Luria's contribution, alas, contains only what he has already published in English, notably in two articles in *Word* (1959). Geschwind's paper, though mildly stimulating, is too brief and discursive to have any real hitting-power Howes, who in an earlier paper in the symposium had presented his well known data on word-frequency distributions in aphasia, again examines the implications of these findings for a theoretical view of the language mechanisms Chase does his best to bring the whole symposium to a focus in such a way as to catch hold of any neurophysiological implications there might be, but these remain potential rather than apparent He is clearly hampered by the mass of doubtfully relevant material assembled by the symposiasts, and his effort only seems to reveal the marginal utility of this kind of scientific communication in a field unsuited to it R C OLDFIELD

APOTHECARIES AND THEIR PAST

The Worshipful Society of Apothecaries of London

A History, 1617–1967 By W S C Copeman Pp 112+19 plates (Oxford, London and New York Pergamon Press, 1967) 63*s*

Last year members of the Worshipful Society of Apothecaries of London celebrated the three hundred and fiftieth anniversary of their foundation as a City Livery Company In 1617, James I granted them a Royal Charter and Dr Copeman's book commemorates this foundation and gives a very brief, but attractively illustrated, account of the society's history The development of the society from activities such as the growing and compounding of drugs to a body which after 1815 was made responsible for the training of the general practitioner is engagingly retold There are also potted biographies of a few of the more famous apothecaries, such as the founder of the society, Gideon de Laune, the poet John Keats, John Hughlings Jackson, Sir Charles Dodds, Sir Arthur Porritt and others

The present Apothecaries Great Hall which was built during the period 1668 to 1670 is itself of note, for it is claimed to be the only Livery Hall out of thirty-six existing in 1939 to escape unscathed the ravages of the Second World War, it is said to be "the oldest surviving hall of any City Livery Company and the oldest medical building still in use in the country" (page x) Dr Copeman has included a list of the paintings it possesses as well as a roll of past masters of the society The superb photographs demonstrate the hall's beauty and elegance, as well as showing some of its possessions

This book will serve as a useful résumé of the authoritative and scholarly history of the society compiled by C Wall, H C Cameron and E A Underwood, the first volume of which appeared in 1963 It will also help to emphasize the important part that the apothecaries have played in the creation of our medicine of today and the part they will continue to take in the prevention and cure of disease in the future

Edwin Clarke

HOW TO FIND A SCIENTIST

Who's Who in Science in Europe

A New Reference Guide to West European Scientists Vol 1 Pp 1–560 Vol 2 Pp 561–1144 Vol 3 Pp 1145–1747 (Guernsey, C I Francis Hodgson, Ltd, 1967) 200*s* , $29 each volume

At first glance, intending users of this new reference book may be misled into thinking that it covers scientists in all European countries A second look will confirm that it does in fact cover only West European scientists to the exclusion of all those in the "eastern bloc" Nevertheless, it is the first guide to West European scientists to be published, and as such should serve a useful purpose in libraries, particularly now that there are several joint scientific organizations in Europe and more and not less co-operation is likely in the future

It is stated in the introduction that there are more than 30,000 entries covering all the "more important European scientists and technologists and those who have interests in the field of research or who are interested in encouraging or promoting science and technology" It is not clear what criteria were used in the selection of entries Help was apparently sought from various international and national organizations, government departments, universities and science-based industrial firms Questionnaires were also used This claims to be a "Who's Who", rather than a "Directory", and so one can hardly expect the comprehensiveness of the national directories of scientists, for example the *Directory of British Scientists* (*DOBS*) and its equivalent in other countries *DOBS*, for example, includes school teachers and research students—categories obviously excluded from the book under review The scope of *Who's Who in Science in Europe* appears, however, to be wider than *DOBS* in some respects, for it includes important doctors, technologists and industrialists—which *DOBS* appears not to do, perhaps because these persons are covered sufficiently well in other British directories

The British representatives in the book appear to be of the level of those in *Who's Who* [in Britain]—professors, Fellows of the Royal Society, and so on Readers in university departments do not appear to be included, but heads of industrial and government research departments, chairmen and council members of the important scientific societies are The comprehensiveness of a book like this, however, can only really be discovered through use. It is also not easy to judge the representation of scientists in countries other than Britain, although superficial examination shows no very marked British bias There must have been difficulties in the selection of entries just on the grounds that titles and status of, for example, professors vary from one country to another

Biographical details given vary in length from name and address only, to details of degrees, subject interest, higher education, recent appointments, society membership, and scientific interests Publications have not been included, but it is useful to have the person's year of birth in some (but not all) of the entries The entries are easy to read—a minor fault is the lack of bold type to distinguish each name An unfortunate omission is that there is no explanation of abbreviations used Not many are used apart from degrees, but a scientist overseas might want to know what FRCS, ACORD and MRS mean

Sarah Bunney

OBITUARIES

Dr Shuhei Fujitaka

Dr Shuhei Fujitaka, who died in Tokyo on November 26, 1967, at the age of sixty, was a brilliant high voltage engineer and educationalist

Fujitaka was born in 1907 at Nara, Japan In 1931 a year after graduating in electrical engineering from Tokyo Imperial University, he became assistant professor at the Tokyo Institute of Technology at Ōokayama In 1943 he became a full professor of Tokyo Imperial University and was attached to the second engineering department

Early in his career Fujitaka was involved in high voltage engineering, and worked on transmission problems After the end of the Second World War the power shortage in Japan was at its worst—the domestic electricity supply dropped to seventy-five volts—and the national policy was to reconstruct the power industry Fujitaka was involved in the development of the 215 kV Shinhokuriku line, from Shinaimoto to Hirakata, which was one of the most important power sources in the town of Kurobe

Fujitaka also participated in national electrification schemes, notably the Jyoetsu line, from Ueno to Niigata He was the first to employ a one step transformer connexion from 66 kV to 1 5 kV, a system which is economical in railway electrification and is now employed by the Japanese National Railways at their substations Fujitaka had recently been working on the new 500 kV line which crosses Japan from east to west

Fujitaka had taught high voltage engineering since joining the Tokyo Institute of Technology in 1931 He also held positions as vice-chairman of the Institution of Electrical Engineers of Japan, as a member of both the regular committee of the International Conference on Large Electric High Tension Systems and the Japanese National Committee of the International Electrotechnical Commission

Sueo Yamakura

University News:

Birmingham

Dr John Hardwicke and Dr Kenneth Walton, both at present readers in the Department of Experimental Pathology, have been appointed to the newly established additional chairs of experimental pathology

Keele

Professor R J Frankenberg, reader in sociology in the University of Manchester and at present on secondment as professor of sociology and dean of the School of Humanities and Social Sciences in the University of Zambia, has been appointed professor of sociology and head of the Department of Sociology

Sheffield

Dr P N Robson, at present reader in electrical engineering in University College, London, has been appointed to the second chair of electronic and electrical engineering

Appointments

The Minister of Technology has appointed the following new members to the Advisory Council on Technology *Dr J M Hill*, chairman of the UK Atomic Energy Authority, *Sir Frank Schon*, part-time member of the Industrial Reorganization Corporation and of the National Research Development Corporation and a non-executive director of the Associated Portland Cement Manufacturers, Ltd, *Sir William Swallow*, chairman of the Shipbuilding Industry Board, *Lord Wright of Ashton-under-Lyne*, general secretary of the Amalgamated Weavers' Association and present chairman of the Trades Union Congress.

Sir John Henniker-Major, at present assistant under-secretary at the Foreign Office, supervising the African departments, has been appointed director-general of the British Council in succession to Sir Paul Sinker

Announcements

The Royal Geographical Society has made the following awards *Founder's Medal* to W B Harland, Sedgwick Museum, Cambridge, for Arctic exploration and research, *Patron's Medal* to Professor A Gansser, Federal Institute of Technology, Zurich, for geological exploration and mapping of the Himalaya

The Seventh James B Macelwane Award is to be presented to Michael B McElroy of Kitt Peak National Observatory, near Tucson, Arizona, at the annual meeting of the American Geophysical Union This award is given each year to a young scientist in recognition of his work in geophysical research

Meetings

Stereochemistry of Macromolecules, May 21–24, Venezia (Dr Giuseppe Zerbi, Istituto di Chimica Industriale del Politecnico, Piazza L da Vinci 32, Milano)

Surging Glaciers, June 6–8, Banff (C M Lockwood, Assistant Director, Department of Extension, University of Alberta, Edmonton, Alberta, Canada)

New Olefin Reactions, June 25–26, University of Manchester Institute of Science and Technology (Professor R N Haszeldine, University of Manchester Institute of Science and Technology, PO Box No 88, Sackville Street, Manchester 1)

Carbon and Graphite, July 2–5, University of Newcastle upon Tyne (Dr T E O'Hair, Department of Physical Chemistry, University of Newcastle upon Tyne, Newcastle upon Tyne 1)

Molecular Crystal Symposium, July 8–12, Technical University "Twente", Enschede (Professor J Kommandeur, Laboratory for Physical Chemistry, The University, Bloemsingel 10, Groningen, The Netherlands)

Chemistry of Natural Products, July 8–13, London (The Secretary, 5th International Symposium on the Chemistry of Natural Products, c/o The Chemical Society, Burlington House, London W1)

Crystal Growth, July 15–19, University of Birmingham (Professor A. D McQuillan, Department of Physical Metallurgy and Materials Science, University of Birmingham, Birmingham 15)

Pattern Recognition, July 29–31, National Physical Laboratory, Teddington (The Conference Department, Institution of Electrical Engineers, Savoy Place, London WC2)

Erratum In the article "Histochemical and Biochemical Study of Synaptic Lysosomes" by Mildred K Gordon *et al* (*Nature*, 217, 523, 1968) the name of one of the authors, Klaus G Bensch, was misspelt

Erratum The address of Dr R Spitzer, the author of the communication "Possible Explanation of Anomalies in Neutral *K* Phenomena" (*Nature*, 217, 943, 1968), should be Lawrence Radiation Laboratory, Livermore, California

Erratum In the introduction to the article "Urinary Metabolites in Parkinson's Disease" by Frederick A Kuehl, jun , *et al* (*Nature*, 217, 136, 1968), the word tryptamine should read tryptophan

Erratum In the communication "Effect of Cocaine, Desipramine and Angiotensin on Uptake of Noradrenaline in Tissues of Pithed Rats" by D T Pals and F D Masucci (*Nature*, 217, 772, 1968), the second sentence of the fourth paragraph should read "The variation of radioactivity recoverable was probably a result of the presence of different numbers of sympathetic nerve endings in these tissues" In the final paragraph the words facilitated and facilitation should read potentiated and potentiation, respectively

CORRESPONDENCE

The Magic of Numbers

Sir,—In your leading article of March 2 (*Nature*, 217, 793, 1968) you surmise that the 87 5 per cent of all scientists who, according to the "First Law of Research on Research", have ever been alive are alive now would be a ratio which would also probably have been valid in 450 BC In fact, if this law is true at all this ratio can be shown to have been valid almost always

Assume that the number of scientists increases by a ratio q (>1) per decade Then n decades after the first scientist, say Archimedes, there will therefore be q^n scientists alive The total number of scientists who have ever lived will be $(q^n-1)/(q-1)$ The ratio of those living in the nth decade to those who have ever lived will be $q^n(q-1)/(q^n-1)$ When n is large enough, say several tens of decades (q not being too near to 1), this ratio becomes equal to $(q-1)$ and is no longer dependent on n

If $q-1=0\ 875$, this would mean that scientists increase by a factor of 1 875 per decade But why per decade? Or better, which is the right unit of time to choose?

Yours faithfully,

K. Schiller

97 Repton Road,
West Bridgford,
Nottingham

FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Monday, March 18

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2), at 10 a m —Colloquium on "Threshold Extension Techniques"

SOCIETY OF CHEMICAL INDUSTRY, PESTICIDES GROUP (at 14 Belgrave Square, London, SW1), at 5 p m —Mr J A R Bates "A Review of Governmental Control in Various Countries"

UNIVERSITY OF LONDON (at the Royal Veterinary College, Royal College Street, London, NW1), at 5 p m —Professor J R Buchanan (Pennsylvania) "Radiology of the Canine Heart" *

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2), at 5 30 p m —Discussion Meeting on "The Class Structure of the British Single-phase House Service Meter" opened by Mr A J Baggott *

UNIVERSITY OF LONDON (in the Gustave Tuck Theatre, University College London, Gower Street, London, WC1), at 5 30 p m —Professor Horst Kunze (Director General of the German State Library, East Berlin) "The Training of Scientific Librarians and Documentalists in Eastern Germany" *

INSTITUTION OF ELECTRONIC AND RADIO ENGINEERS, INSTRUMENTATION AND CONTROL GROUP (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, WC1), at 6 p m —Professor H H Rosenbrock "Control Past, Present and Future" (Inaugural Meeting)

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, WC2), at 6 p m —Professor Owen Lattimore "China To-day—Some Social Aspects" (first of three Cantor Lectures)

Tuesday, March 19

INSTITUTION OF ELECTRICAL ENGINEERS (joint meeting with the Automatic Control Group of the I Mech E , at Savoy Place, London, WC2), at 10 a m —Colloquium on "Engineering Aspects of Satellite Design"

SOCIETY OF CHEMICAL INDUSTRY, AGRICULTURE GROUP (at 14 Belgrave Square, London, SW1), at 10 a m —Meeting on "Soil Analysis and Fertilizer Recommendations"

UNIVERSITY OF LONDON (at the Royal Veterinary College, Royal College Street, London, NW1), at 5 p m.—Professor James W Buchanan (University of Pennsylvania) "Cardiovascular Surgery in Dogs" *

BRITISH SOCIETY FOR THE HISTORY OF SCIENCE (in the Lecture Theatre of the Science Museum, Exhibition Road, London, SW7), at 5 30 p m —Mr W F Grimes "The Development of Archaeological Techniques"

ROYAL INSTITUTION (at 21 Albemarle Street, London, W1), at 5 30 p m —Professor R L F Boyd "Recent Studies of the Planet Venus" (Lecture for Sixth Form Pupils from Schools in London and the Home Counties To be repeated on March 20, 26 and 27)

UNIVERSITY OF LONDON (at Imperial College of Science and Technology, London, SW7), at 5 30 p m —Professor T R E Southwood "The Abundance of Animals" (Inaugural Lecture) *

INSTITUTION OF ELECTRONIC AND RADIO ENGINEERS, COMMUNICATIONS GROUP (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, WC1), at 6 p m —Mr W D Benson and Mr B Buckingham "Integrated Circuits for Radio Receivers"

INSTITUTION OF MECHANICAL ENGINEERS, EDUCATION AND TRAINING GROUP (at 1 Birdcage Walk, Westminster, London, SW1), at 6 p m —Discussion Meeting on "Teaching of Materials Science"

Wednesday, March 20

INSTITUTION OF MECHANICAL ENGINEERS, MANUFACTURE AND MANAGEMENT GROUP (at 1 Birdcage Walk, Westminster, London, SW1)—All-day Discussion Meeting on "A New Approach to Machine Tools in Relation to the Components They Make"

BRITISH COMPUTER SOCIETY (at Queen Elizabeth Hall, London, SE1), at 9 a m —Symposium on "Production Control by Computers—Where are We Going ?"

INSTITUTE OF NAVIGATION (at the Royal Institution of Naval Architects, 10 Upper Belgrave Street, London, SW1), at 3 p m —Dr D E Karwath "Navigation of Supersonic Transport"

UNIVERSITY OF LONDON (at the Institute of Diseases of the Chest, Brompton Hospital, London, SW3), at 5 p m —Dr D P Winstanley "Pulmonary Embolism" *

ROYAL STATISTICAL SOCIETY (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, WC1), at 5 15 p m —Discussion Meeting on "Regression Methods"

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2), at 5 30 p m —Mr W J Quill "Satellite Communications"

Thursday, March 21

LONDON MATHEMATICAL SOCIETY (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W1)—Professor L Nirenberg "Pseudo-differential Operators"

SOCIETY OF CHEMICAL INDUSTRY, ROAD AND BUILDING MATERIALS GROUP (at Victoria Halls, Bloomsbury Square, London, WC1), All-day Meeting on "Some Modern Laboratory Techniques Applied to the Study of Road and Building Materials"

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2), at 2 30 p m —Colloquium on "The Role of the Computer in Device, Circuit and Equipment Design"

ROYAL SOCIETY (at 6 Carlton House Terrace, London, SW1), at 4 15 p m —Meeting for the election of Fellows 4 30 p m —Dr H Kronberger, FRS "Hydrostatic Extrusion" (Review Lecture)

INSTITUTION OF MINING AND METALLURGY (at the Geological Society of London, Burlington House, Piccadilly, London, W1), at 5 p m —Mr R Jeffrey "Physical Metallurgy and Safety in Mines", Mr R H Lamb and Mr L R Verney "Investigations into RST Group Concentrator Practices", Dr M J Gallagher "Determination of Molybdenum, Iron and Titanium in Ores and Rocks by Portable Radioisotope X-ray Fluorescence Analyser"

INSTITUTE OF PETROLEUM, EXPLORATION AND PRODUCTION GROUP (at 61 New Cavendish Street, London, W1), at 5 30 p m —Mr R B Hyde "Abnormal Formation Pressures—Their Origin, Distribution, and Control Whilst Drilling"

INSTITUTION OF MECHANICAL ENGINEERS, NUCLEAR ENERGY GROUP (at 1 Birdcage Walk, Westminster, London, SW1), at 6 p m —Discussion Meeting on "Role of Research and Development in the Support of Design"

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE (at the Royal Army Medical College, Millbank, London, SW1), at 7 30 p m —Laboratory Meeting Chairman Professor P C C Garnham, CMG, FRS

Thursday, March 21—Friday, March 22

SOCIETY OF CHEMICAL INDUSTRY, FOOD GROUP and OILS AND FATS GROUP (at the School of Pharmacy, Brunswick Square, London, WC1)—Symposium on "The Functions of Natural and Synthetic Surface-Active Lipids in Foods"

Friday, March 22

ARBORICULTURAL ASSOCIATION (in the Lecture Room, Royal Horticultural Society's New Hall, Greycoat Street, London, SW1), at 6 30 p m —Dr Francis Rose "Woodland Ecology and Conservation"

Monday, March 25

INSTITUTION OF ELECTRICAL ENGINEERS (joint meeting with the Automatic Control Group of the I Mech E , at Savoy Place, London, WC2), at 5 30 p m —Discussion Meeting on "Fluidics and Integrated Circuits" opened by Dr R C Foss and Dr K Foster

INSTITUTION OF MECHANICAL ENGINEERS, AUTOMOBILE DIVISION (at 1 Birdcage Walk, Westminster, London, SW1), at 6 p m —Discussion Meeting on "The Impact of Proposed Vehicle Noise Regulations"

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, WC2), at 6 p m —Dr C H G Oldham "China To day—Science" (Second of three Cantor Lectures)

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned

LECTURERS and ASSISTANT LECTURERS IN CHEMISTRY—The Registrar, University of Manchester, Manchester, 13, quoting Ref 20/68/Na (March 22)

ASSISTANT LECTURER (with an honours degree in pharmacology, physiology, biochemistry or pharmacy, and preferably a higher degree or research experience) IN PHARMACOLOGY—Clerk to the Council, The School of Pharmacy, University of London, 29/39 Brunswick Square, London, WC1 (March 25)

LECTURER or ASSISTANT LECTURER IN THE PHILOSOPHY OF SCIENCE—The Secretary, The University, Aberdeen, Scotland (March 25)

SENIOR EXPERIMENTAL OFFICER in the DEPARTMENT OF APPLIED PHYSICS to work on the crystallographic perfection of photoconductive and electroluminescent materials using a JEM-120 metallurgical electron microscope—The Registrar and Secretary, University of Durham, Old Shire Hall, Durham (March 25)

SENIOR LECTURER, LECTURER or ASSISTANT LECTURER (three vacancies) in PSYCHOLOGY—The Secretary, The University, Aberdeen, Scotland (March 25)

LECTURER (with a degree in sociology, social anthropology or psychology, and experience of industrial research) in INDUSTRIAL SOCIOLOGY—The Registrar, University of Warwick, Coventry, CV4 7AL, Warwickshire (March 29)

SENIOR LECTURER (graduate in physiology, biochemistry or related subjects, or with a medical qualification registrable in the United Kingdom) in PHYSIOLOGY—The Registrar, University of Manchester, Manchester 13, quoting Ref 25/68/Na (March 29)

LECTURER and an ASSISTANT LECTURER in the PHYSIOLOGY DEPARTMENT —The Secretary, Queen Elizabeth College (University of London), Campden Hill Road, London, W8 (March 31)

PRINCIPAL LECTURER, SENIOR LECTURER and a LECTURER (Grade II) in SOCIOLOGY—The Academic Registrar, Hatfield College of Technology, Hatfield, Herts (April 1)

CHAIR in the DEPARTMENT OF MATHEMATICS in the Faculty of Science, University of Malaya—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (London and Kuala Lumpur, April 8)

VISITING LECTURER in CHEMISTRY at the University of Canterbury, Christchurch New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (April 8)

SENIOR LECTURER or LECTURER in MORBID ANATOMY in the DEPARTMENT OF PATHOLOGY, University of the West Indies, Jamaica—The Inter-University Council, 33 Bedford Place, London, WC1 (April 10)

PROFESSOR (with interests in some field of physical geography, such as quaternary geomorphology, physical geography in its application to planning, particularly conservation of natural resources, quantitative analysis in physical geography) in the DEPARTMENT OF GEOGRAPHY—The Registrar, Room 39, ORB, The University, Reading (April 11)

LECTURER IN PHILOSOPHY at Massey University, Palmerston North, New Zealand—The Secretary-General, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (New Zealand and London, April 15)

SECRETARY (senior experienced administrator preferably with a scientific or technological background) of the BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE—The President, Dame Kathleen Lonsdale, DBE, FRS, University College London, Gower Street, London, WC1 (April 30)

ASSISTANT LECTURER or LECTURER (biochemist or microbiologist) in the DEPARTMENT OF BIOCHEMISTRY AND AGRICULTURAL BIOCHEMISTRY—The Registrar, University College of Wales, Aberystwyth

BASIC GRADE BIOCHEMIST for routine chemical pathology laboratory—The Assistant Secretary, University College Hospital, Gower Street, London, WC1

CHAIR OF CHILD HEALTH at King's College Hospital Medical School—The Academic Registrar (A), University of London, Senate House, London, WC1

MASTER to teach MATHEMATICS at all levels, including the Sixth Form—The Master, Dulwich College, London, SE21

SRC RESEARCH ASSISTANT (graduate in chemistry) to Dr G D Parfitt in the DEPARTMENT OF CHEMISTRY, for work involving an experimental study of the coagulation of colloidal systems involving mixtures of solid particles (hetero-coagulation)—Dr G D Parfitt, Department of Chemistry, The University, Nottingham

HOW TO BUY NATURE

Volumes start in January, April, July and October, but subscriptions may begin with any issue

The direct postal price per subscription for one or two copies of NATURE each week is

***12 MONTHS** (52 issues and 4 indexes)

Great Britain and Eire **£14 0 0** each
United States of America (by air freight) **$48** each
Canada (by air freight) **$52** each
Elsewhere overseas by surface mail **£14 0 0** each
(Charge for delivery by air mail on application)

*Shorter periods *pro rata* (Minimum three months)

Professor Watson's Memoirs

THE publication in the United States of Professor J D Watson's book *The Double Helix* has established a claim on polite conversation which is not entirely stifled even by public concern about the relationship between gold and the dollar or even by the drama of the first manoeuvres in the election of a new president That, to say the least of it, is a proof of the importance of a book intended to provide a full account of the way in which, in the early fifties, Watson and Crick felt or fumbled their way towards a correct structure for the DNA molecule Professor Watson's book is not, however, a formal history but rather a personal recollection of events—a memoir Many will dissent from his assertion, in a preface, that "no-one will ever be able to write a definitive history of how the structure was established", but in any case this is not Professor Watson's chief concern He is quite honestly, and quite properly, concerned to convey the flavour of how scientific research is ' done", to use his own words In doing so he has necessarily flown in the face of several conventions, literary and social This in turn has no doubt lost him his place on a good many Christmas card lists, but that is his concern

In the circumstances, an objective appraisal of the value of the book as literature or as history is probably too much to hope for Most critics so far have been deprecatory and somewhat patronizing, but they have usually also been in positions to feel threatened, directly or otherwise, by what Professor Watson has to say It will be easier to tell when *The Double Helix* is eventually published in Britain two months from now, after what must seem an absurd delay In the meantime, however, there is no doubt that Professor Watson has written a rattling good yarn, quite spellbinding. It bounces along like a detective story and will probably be a great success This is a tribute to Professor Watson's engaging candour He might have been better than Boswell and certainly funnier

There remains the question of how the issues of principle raised by the book are to be dealt with The first thing to acknowledge, however, is that there should be no difficulty at all in what seems most commonly to have been the offence—the way in which this personal account of events is necessarily subjective and even distorting If, for example, one of the participants is repeatedly presented as over-ebullient or over-cautious, this is to be read more as a comment on the relationship between Professor Watson and the people concerned than as a truth that the qualities described are real If some people seem larger than life, or smaller than life, it may well be that the fault lies in Professor Watson and not his cast of characters To be sure, publication of the book will be a chastening experience for many molecular biologists, and some of them, no doubt, will be offended, but that is one of the hazards of this kind of literature

The way in which the book is larded out with tales of Professor Watson's pursuit of young women at Cambridge may also seem to other participants to be undignified Others, however, may recognize that unmarried graduate students often share the same weaknesses In reality, these and other incidents in the book are one of the sources of its credibility and a valuable clue to Professor Watson's estimation of his own part in the problem of DNA If, of course, his picture is seriously awry, then other people are free to protest and even have a duty to do so It is not enough simply to resolve never again to invite Professor Watson to tea and biscuits

It is in passing worth remarking that the techniques which have been used in constructing this book are commonly and rightly eschewed by professional reporters as a means of getting at the truth What Professor Watson has done is to write down the often unguarded statements of those concerned with the working out of DNA The trouble, of course, is that statements like these may be misleading If X complains angrily of Y, for example, it does not follow that the complaint is justified, or even that X is habitually hostile to Y To know the truth, both X and Y must be cross-examined by some third party and even then the truth may be elusive

These, however, are almost technical objections and certainly do not suggest that *The Double Helix* should never have been published The way in which this enthralling book provides non-professional readers with an occasional unseemly view of science and of research is another issue likely to lose Professor Watson friends But is he wrong ? A good deal of what he has to say, for example, about the sense of competition between the group at Cambridge and its rivals—real and imaginary—elsewhere may come as something of a shock to those outside But is competitiveness all that uncommon ? And is it sensible of professional scientists sometimes to pretend that feelings like this never sully the state of science ? In fact what Professor Watson has done is to provide a much more real appraisal of the character of science in the laboratory than other published statements of a more formal kind He has done something to ensure that science will become less pompous than it is For all the faults which may be found in *The Double Helix*, this is a considerable public service

Time for a Change of Policy

THE worst epidemic of foot and mouth disease in the history of British farming seems to have run its course, although a fresh outbreak of the disease, confirmed last Monday, has delayed yet again the lifting of all restrictions on the movement of livestock. 423,029 cattle, sheep, pigs and goats have been slaughtered since last October, and the British Government has paid £26·5 million in direct compensation. Added to this are countless consequential costs, so the total bill could be as high as £100 million. Have any lessons been learnt? It is early days yet, but judging from the Government's actions to date the answer must be very few.

The Reid report (see *Nature*, **217**, 894; 1968) came to the conclusion that lamb imported from the Argentine was the most likely source of the infection. Tourists, the birds, the wind, hay and straw were all exonerated. It is true that the evidence for this conclusion is only circumstantial, and quite naturally the Argentinians, with an annual £40 million worth of meat exports at stake, dispute it, but it is in keeping with the findings of the Gowers Committee of 1952–54. Why then has the British Government, in the face of vehement opposition from the farmers and apathy from everyone else, decided to resume importing beef, but not mutton, from Argentina from April 15? It must believe that it is in the national interest once again to risk the chance of an epidemic, which will always be present so long as meat is imported from South America under the existing conditions of inspection, so as to obtain inexpensive beef when home supplies are at their lowest. The Government may win its gamble, and everybody hopes that it will. But if its intention is to prevent re-infection, the decision to ban mutton while importing beef is completely absurd. Both animals are affected by the disease—in the past more outbreaks have been caused by contaminated beef than mutton—and it can only be fortuitous that mutton rather than beef caused the recent epidemic.

As part of the grand post-mortem Mr Fred Peart, the Minister of Agriculture, has asked the Duke of Northumberland to be chairman of a seven man committee "to review the policy and arrangements for dealing with foot and mouth disease in Great Britain and to make recommendations", and the committee intends to collect all its evidence by May 31. The Gowers Committee of 1952–54, which was the last to consider this, came out firmly in favour of maintaining the traditional slaughter policy and prohibiting vaccination. As a result, the no vaccination policy has become an inflexible national dogma—a very expensive dogma as it has turned out—not a policy. What is even worse in the long term is that research into vaccines, methods of vaccination and the epidemiology of foot and mouth disease has been woefully under-financed. Perhaps, now it is too late, some thought will be given to stepping up research to the critical point.

The claim is that once vaccination is permitted, foot and mouth disease will become endemic and that vaccination of all the livestock in Britain is hopelessly expensive. (In 1954 the Gowers Committee estimated it would cost £25 million to vaccinate sheep, pigs and cattle three times a year.) Recent experience in France, however, seems to suggest otherwise and the Northumberland Committee would do well to recognize this.

FRANCE

Year	Individual outbreaks	Totals of livestock slaughtered	Vaccine strains
1959	6,188	116,016	—
1960	7,381	130,880	—
1961	2,627	65,468	—
1962	191	11,790	O_2A_5C
1963	28	1,129	O_2A_5C
1964	56	5,016	—
1965	10	1,608	OO_2A_5C
1966	59	4,190	OO_2A_5C
1967	17	2,045	OO_1,O_2A_5C
1968	3 so far		

The French National Herd comprises 21·184m cattle, 9·186m sheep, 9·840m pigs and 1·018m goats.

GREAT BRITAIN

Year	Individual outbreaks	Total livestock slaughtered
1959	45	7,000
1960	298	70,000
1961	103	25,000
1962	5	1,000
1963	nil	
1964	nil	
1965	1	200
1966	34	45,700
1967	2,210	390,000
1968	Over 100 so far	130,000 so far

The British National Herd comprises 12·342m cattle, 28·885m sheep and 7·107m pigs.

Nobody can seriously claim that foot and mouth disease is endemic in France where, since 1962, all cattle over six months old, but not sheep and pigs, have been compulsorily vaccinated just once a year. Indeed, as the table shows, since compulsory vaccination began there has been a hundredfold decline in the incidence of the disease. What about cost? Each vaccination costs about 3·5s., of which the French Government pays a little less than half. When an outbreak occurs, however, all livestock on the infected farm is destroyed and livestock movement is controlled as in Britain. The total annual cost of this combined vaccination and slaughter policy has, since its introduction, averaged out at about £1·5 million, and the French National Herd of cattle is about 21·184 million head compared with the British 12·342 million head. On this basis, for the price of the recent epidemic, all the cattle in Britain could have been vaccinated for 20 to 25 years. Alternatively, the cattle and those of the 28·885 million sheep in Britain that are readily accessible could have been vaccinated for something like 10 years.

The French also have an answer to the naive argument that it is impossible to vaccinate against all fifty-six strains of foot and mouth virus and so there is no point in any vaccination at all They follow continually the epidemiology of the various strains present in Europe and the countries with which they trade, and progressively change to the appropriate strains No doubt they are now producing vaccine against A_{22}, a strain loose in the USSR

The fact that Holland, Belgium and Germany also have combined vaccination and slaughter policy argues strongly for it Is it not time for Britain to follow suit ? Even if the Northumberland Committee decides that vaccination of the entire National Herd is not practical, voluntary vaccination and compulsory vaccination to cordon off centres of infection should be used in the future The folly of prohibiting vaccination while risking infection by importing South American meat ought by now to be apparent to everyone

Mr Peart should now waste no time in tightening the inadequate inspection control arrangements for imported meat As a starting point, there is the recent and overdue Argentinian proposal for an exchange of British and Argentinian experts to see what can be done to improve checks for the disease A three man British veterinary mission will leave for Buenos Aires on March 17 The present arrangements with the Argentine date from the Bledisloe agreement of 1928 and provide only for a visual inspection, by local veterinary officers, of cattle on the farms and at the slaughter and packing plants Any animal which is either incubating the disease or is a carrier will simply not be detected by visual inspection without quarantine, so there will always be a risk that meat is infected Furthermore, because of local conditions, a declaration from the farmer is accepted instead of veterinary inspection at the farm These forty year old arrangements are just not good enough The disease must be detected before slaughtering by stringent inspection, for it is certainly hopeless to try systematically to check for foot and mouth virus in the bones of refrigerated carcasses

A Space Policy for Europe?

by Angela Croome

THE report of the Causse Advisory Committee on Programmes to the European Space Conference (ESC) may well set the pattern for European space developments for the next 10 years After being leaked in *Le Monde* (March 13) the report was released at the end of the meeting of the Alternates Committee of the European Space Conference (not of ESRO as reported last week) in Paris on March 13–14 The report should be followed by action at the next ministerial meeting of the ESC some time this summer —which will mean that a mere two years have elapsed between the setting up of the ESC and the adoption of a programme One spokesman for the British aerospace industry remarked that "it's a great pity that such objectives were not adopted when the two main European space organizations were set up in the early sixties"

The aim of the advisory committee's proposals is a "balanced programme", by which it means a suitable combination of scientific and "useful" satellites and the appropriate means of launching them "European activity in space should be orientated towards direct objectives, namely, increased knowledge and worthwhile applications Rather than seek the 'power' objective that has characterized other space policies, Europe should above all demonstrate her determination to be independent Rather than indulge in illusory competition, she should seek to practise the closest collaboration with the other space powers "

The committee was constrained on the one hand by the level of investment that can reasonably be supported by Western Europe, and on the other by the nature of the proposals actually put forward by European groups These have included candidate projects sponsored by ESRO, ELDO, CETS, Eurospace and Eurovision (the European Broadcasting Union) All these have been assessed by the Technical Subcommittee of five independent experts, after which the economic implications were scrutinized by a larger economic sub-committee representing 13 of the member states of the European Space Conference

The programme that has evolved allows for three options, one of which should be chosen by the ESC for its immediate target (that is, to come to fruition in the early seventies) The options range from one in which priority is given to an ambitious science programme with the Large Astronomical Satellite as its centre-piece and a minimal applications programme, to one with a fairly comprehensive applications content and a minimal scientific satellite programme (averaging 2 scientific satellites a year, each carrying 8–10 sophisticated experiments) This covers the launching period 1973–76 The Large Astronomical Satellite (LAS) gets rather little attention, and seems to be considered a major technological liability, despite its acknowledged scientific potential The technical sub-committee believes that it cannot be attempted by adhering to the ESRO budget for its first 8-year period (1964–72) and that it may be outmoded by US activity by the time it is practicable

The whole programme should be possible if a growth rate of 10 per cent is allowed The analysis concludes that this is well below 1 per cent of the European GNP in the years ahead, assuming an annual growth of 4 per cent (It is estimated that the US is spending roughly 1 per cent of its GNP on space activity) The actual figures are equivalent to $150 million in 1967 against a plateau of $240 million from about 1972 For this, a scientific launching programme of two satellites a year, plus the development of a geostationary TV relay satellite for Eurovision use in the 1970s, is envisaged There would be enough slack to start on one other type of applications vehicle—navigational meteorological or earth resource are all of interest It is pointed out that by dropping LAS, a meteorological satellite can be introduced "giving European meteorologists a chance of taking part in the World Weather Watch in 1973 with a satellite of European construction", and that meteorology incorporates an element of research so that the sacrifice may not seem so bitter

A feature of all the options, and a distinct break with the past, is that all the launchings employ the

European launcher based on the British Blue Streak The adoption of ELDO launchers for the scientific payloads as well as for the applications satellites will put launcher production on a rational basis (an average requirement of four a year) The report points out " . the present situation is indeed unsatisfactory the programme as a whole is neither coherent nor balanced It does not include any applications satellites and the launcher projects are mainly justified by applications satellite projects " It also calls for a sustained development programme for the ELDO vehicle, involving strap-on boosters, liquid hydrogen upper stages and possibly electric propulsion, for the tasks of the later seventies The possible ELDO-4 launcher, for instance, would have about double the capacity of the present ELDO-1 specification and could place 2 tons in geostationary orbit, enabling direct-broadcast colour television to be supplied to all of Europe as well as Africa and the Middle East by 1978. Blue Streak is seen as perfectly suitable for the booster stage throughout the period

A number of decisions are called for by the report, but, the authors point out, four of them are urgent and must be taken by the ministers this year—the future of the LAS, a start on the Eurovision satellite, increase in production of ELDO launchers and statutory bodies to handle the problems of organization But what is needed most is a firm decision to pay ESRO has been living from hand to mouth for two years now

CERN Meeting

THE 37th meeting of the Council of CERN, held last week in Geneva, discussed the progress being made towards the building of the 300 GeV accelerator Most of the progress is at the organizational level, but it now seems clear that a final decision on the project should emerge by the end of this year, probably in December There were also hopeful signs for supporters of the machine that fewer governments are dragging their heels than was the case at the end of last year The United Kingdom delegation, in particular, expressed itself completely satisfied with the answers given on design, cost, management and collaboration, and said that there was now no reason why these issues should be reopened The German delegation was rather more subdued, for reasons of its own, but put forward no major objection

It is now also clear that a decision about the siting of the laboratory should be made in the summer of this year, and a short list of four sites should be ready by June At the moment, nine sites are still under consideration, and technical reports have now been published on each one They are Aspropyrgos in Greece, Doberdo in Italy, Drensteinfurt in Germany, El Escorial in Spain, Focant in Belgium, Gopfritz in Austria, Le Luc in France, Mundford in the United Kingdom and Uppsala in Sweden The final decision will be taken in two stages, a preliminary vote will be used to reduce the number of sites to four, and the delegates last week agreed that this vote should be taken in open ballot, though it is possible that it could be done in closed session But, whatever the choice is to be, it will have to await promises of money which represent a substantial proportion of the cost of the accelerator In other words, countries will have to commit themselves to the project before they know where it is to be built

At the organizational level, the delegates agreed to the formation of a steering committee to work on the 300 GeV project until an advisory committee for the project is formed The function of the advisory committee would be to assist the director-general of the new laboratory, and it might also exercise some form of control As a stopgap arrangement, the steering committee has been set up to fulfil this function, the membership is Professors Amaldi and Amman of Italy, Dr J B Adams and Professor Merrison of the UK, Dr Levy-Mandel of France, Professor Paul of Germany, and Drs Hine and Zilverschoon of CERN, the director-general of CERN is an ex-officio member Several delegates emphasized the need for speed, particularly once the decision to go ahead has been taken Professor Puppi of the Science Policy Committee, for instance, said that the name of a proposed director-general could be put forward very quickly The feeling seems to be that the second the decision is taken, the delegates should dash from the meeting to lay the foundation stone, before anybody can change their minds

Engineers of the World Unite

NATIONAL engineering organizations from all over the world got together recently under the auspices of Unesco to form a World Federation of Engineering Institutions At a meeting in Paris from March 4 to 7, representatives from 60 countries and four regional organizations gave sanction to a plan to set up the federation The hope is that it will do for engineering what the International Council of Scientific Unions does for science—a process of organization, co-operation and, to a limited extent, unification

The World Federation will replace or supplement a number of other international bodies which for reasons of representation or organization were unable to do the job There have been limited groupings of national institutions for a number of years—there was one in Europe, one for the Commonwealth, and another covering the Americas These organizations will no doubt co-exist with the new one quite happily The only organization whose continued existence is threatened is the Union des Associations Techniques Internationales, based in Paris, which has for some time been regarded as something of a lame duck Unesco has been pressing for a new organization for some years, and it seems that its gentle prompting met with a ready response from the national engineering institutions At the Paris conference the federation was set up by a unanimous vote

The first president of the federation will be the Swiss engineer Dr Eric Choisy, and Mr R Gibrat of France will be vice-president It seems likely that much of the executive work of the federation will be done at the Institution of Electrical Engineers in London—the secretary of the institution, Dr G F Gainsborough, has been appointed first secretary-general of the federation The federation itself will consist of national members, which will be the representative engineering body for each country (in Britain the Council of Engineering Institutions), and some international members, representing existing federations throughout the world

Dr Gainsborough is enthusiastic about his new responsibilities Already, he says, two projects have been started The first is to set up a committee to examine the qualifications and continuing development of engineers throughout the world. The ultimate aim, still a long way off, is international recognition of qualifications, so that an engineer from Poland, say, can have his qualifications recognized in Ethiopia. This committee will also help to speed the exchange of ideas in the education of engineers, and should help developing countries which are setting up departments of engineering. The other project started by the federation is to examine the possibilities of a world-wide information system, for dissemination and retrieval. This committee will be collaborating with the abstract board of ICSU. The federation has also started on a more abstract project, that of drawing up an international code of conduct for professional engineers.

The general work of the federation will be financed from contributions from member countries. The special committees, on the other hand, are each charged with responsibility for finding sources of funds for their investigations. Dr Gainsborough is hoping that Unesco, OECD and other international organizations will see the federation as a body worthy of support. There seems every likelihood that this hope will be justified.

No Student Power at Oxford

from our Oxford Correspondent

It was too much to expect the Hebdomadal Council to comment other than adversely on the petition submitted to the Privy Council for various reforms in government of the University of Oxford. One of the three chief proposals of the petition, intended to give undergraduates direct representation in university affairs, would indeed have been without precedent in many less staid institutions. In its letter to the Privy Council, the Hebdomadal Council took an optimistic view of relations within the colleges between undergraduates and senior members, and justified its rejection of the proposal because the Student Representation Council is not highly regarded by the undergraduates themselves. The argument is circular; the SRC is not even recognized by, let alone allowed to participate in, the university government. Its lack of prestige among students is a reflexion of this. But in any case, the council's dismissal of the proposition will doubtless be justified shortly by the anarchic demise of the London School of Economics whose Board of Governors has decided to admit students to certain committees (see *Nature*, **217**, 699; 1968).

A second proposal in the petition is that the convocation of the university's MAs should be made into an active forum, rather than consigned to impotence as it will be under the Franks Commission's recommendations. This proposal indeed seems "unnecessary and undesirable". As the Hebdomadal Council points out, many members of convocation live abroad, and most are too busy to attend sessions.

The rejection of the third proposal of the petition, outlined at some length in *Nature* (**217**, 500; 1968), is not so easily defended. The Hebdomadal Council does not deny that, in the disciplinary procedure of the university, the proctors act both as judges and policemen, so that there is a possibility of bias in the judgment of students' misdeeds. Yet the council (which, it is worth noting, includes proctors) announces its satisfaction with the present arrangements. The council's claim that students are made aware of their right to appeal against proctorial decisions to an independent committee is indeed true. But this has no bearing on what is requested by the petition. If the proctors confined themselves to the carrying out of petty university regulations, such as the licensing of student's cars, then the reform of proctorial procedure would scarcely be worth the attention of the Privy Council, but the Oxford proctors, unlike their Cambridge counterparts, show little reluctance to act in cases where junior members have broken the law of the land, rather than simply that of the university. The proctors' terms of reference are wide and their punishments sometimes severe, and it is only reasonable that the slightest possibility of bias should be eliminated.

Among the signatories of the petition, senior members of the university outnumber juniors by 101 to 29. In its letter to the Privy Council the Hebdomadal Council doubts whether the request of 100 out of the 1,600 members of the congregation (the "parliament of senior members") is enough to justify discussion of major constitutional changes. Yet it is well known that few senior members attend the congregation. Important issues have been decided with less than 200 people present. Outside observers might be expected to be surprised that so great a demand still exists for new reforms 18 months after the Commission of Inquiry issued its report. It will be interesting to see how this consideration weighs with the Privy Council as it studies the petition and the reply.

More Teachers

The latest volume of *Statistics of Education*, 1966 (published by HMSO, price £1) starts on a cheerful note, for between October 1965 and October 1966, the number of students training to be teachers in England and Wales rose by more than 12,000, bringing the total to 88,823. This represents an increase of nearly 75 per cent over the figure of 50,942 for 1962. In addition there were 1,308 men and 654 women in one-year supplementary or advanced courses, and courses of one year for the teaching of handicapped children also showed a marked increase for the same period. Less reassuring is the decline in the proportion of students successfully completing training in both junior and secondary courses, even though the numbers and proportions in infant/junior and junior/secondary courses increased. Another unsatisfactory trend was the fall between 1963 and 1966 in the numbers of courses for secondary school teachers and students for them.

The increase in the total teaching force from 321,000 in 1962 to 349,000 for 1966 was most striking in the colleges of education, where the number of teachers was more than doubled. A 70 per cent increase for further education establishments is also a striking feature. Up to March 31, 1966, 20 per cent of teachers in maintained primary and secondary schools were graduates—the proportions ranging from 75 per cent of teachers in grammar schools to some 4 per cent in primary schools. About 33 per cent of teachers in establishments of further education were graduates, and graduates also accounted for more than 60 per cent of teachers in direct grant grammar schools.

But the figures showing the wastage of qualified teachers are dismally high. Thus between 1965 and 1966, 9,000 qualified men teachers entered maintained primary and secondary schools, and in the same period 7,000 left the schools. Wastage was greatest among those under thirty, and was also high among untrained graduates under 25. The comparable figure for women was even higher—representing 13 per cent of those qualified and in service, and wastage was again high among untrained graduates. Significant proportions of this wastage could, however, be attributed to transfer from one teaching establishment to another, although among qualified women teachers only 1,000 out of a total of 20,000 transferred in this way.

NUMBERS OF STUDENTS IN COLLEGES OF EDUCATION AND UNIVERSITY DEPARTMENTS OF EDUCATION (other than supplementary courses)

Numbers of students	1956–57	Oct 1962	Oct 1964	Oct 1965	Oct 1966
In university departments of education	2,512	3,260	3,739	3,695	3,192
In colleges of education	26,039	47,682	62,112	72,856	84,911

The last page in the report lists the salaries of teachers in colleges of education at March 31, 1966. For male graduates the average salary was £1,539 for those under thirty, rising to an average of £2,674 for those aged 60 and over; figures for women graduates were very similar. Male non-graduates received some £100 less under the age of 30, and about £140 less over the age of 60.

Change on Blood Tests

THE British Home Office seems to be modifying slightly its attitude to the tests by which motorists in Britain can now be convicted of driving under the influence of alcohol. A recent paper in *Nature* by Professor J. B. Payne, Dr D. W. Hill and Mr D. G. L. Wood of the Royal College of Surgeons (**217**, 963; 1968) suggests that the methods used by police authorities for carrying out the tests are far from accurate. The method by which the amount of alcohol in the bloodstream is estimated from the amount in the urine seems particularly suspect. So far the Home Office has not been forced to act, because no motorist accused of driving under the influence of drink has quoted Professor Payne's work in his defence.

Although the Home Office has not changed its views on the urine test, there does seem to have been a shift of emphasis in the blood tests. Originally, after advice from the medical associations, police surgeons were advised to take small samples of capillary blood for use in the test, although it was also open to them to take venous blood if they preferred. The work at the Royal College of Surgeons suggests that the latter is likely to give more accurate results, because of the way in which the alcohol tends to become more concentrated in the plasma than in the red blood cells. Blood taken from capillaries can often contain more plasma than blood from veins, so that the capillary method can give anomalously high readings, with the possibility of conviction for a driver who is in fact under the limit.

The Home Office has now sent a circular to police authorities pointing out that it is within their discretion to take venous rather than capillary blood. The police authorities are advised by the Home Office always to have available a supply of syringes with which venous blood samples can be taken. The motorist can still decide which method he prefers, though the doctor will be at liberty to advise the syringe method if he thinks fit. The circular also points out that the motorist has the right to keep a sample of his own blood for independent analysis, and that these samples should be sealed, stored in a cool place, and analysed with the minimum of delay.

So far, this is no more than a recommendation from the Home Office to the police authorities. Both methods of taking blood are still legal, and the circular says nothing of the inaccuracies of the urine test. But in the event of a driver being acquitted because of the inaccuracies which Professor Payne and his colleagues have discovered, the Home Office would doubtless have to act very much more decisively. Whether the work provides new grounds for appeal for those already convicted under the existing law has yet to be tested, but there is an urgent need to clarify the situation. Sooner or later the Home Office will be forced to set about the task.

Preserving the Bastard Toadflax

THE Nature Conservancy has announced two new nature reserves and an extension to another, bringing the total number of national nature reserves to 124, covering 257,239 acres.

One of the new reserves is in the central part of the range of chalk hills forming the northern scarp of the Vale of Pewsey seven miles south-west of Marlborough. It is a fine example of unreclaimed chalk downland, and it has long been known to botanists and entomologists for its rich plant and insect life. Extending from Milk Hill in the west to Knap Hill in the east, the reserve covers 188 acres and it has been established by agreement with New College, Oxford, and the agricultural tenant. The summit of Milk Hill (964 ft) is the highest point in Wiltshire. Examples of plants found in the reserve are round-headed rampion, field fleawort, bastard toadflax and several orchids. The Chalk Hill Blue and the Brown Argus are two of the butterflies found. There are also several features of archaeological and historical interest. One of the best examples of a neolithic causeway camp lies on Knap Hill, and there is also a chambered long barrow known as Adams Grave on Walkers Hill.

The other new reserve is at Ebbot Gorge, Somerset,

North part of Hartland Moor, Isle of Purbeck (Crown copyright).

on the southern face of the Mendip Hills near Wells It was presented to the National Trust by Mrs Gerard Hodgkinson in 1967 in memory of Sir Winston Churchill and it is being managed by the conservancy under a lease The reserve covers 101 acres and includes a dry gorge of carboniferous limestone There are several small caverns in the gorge where the remains of reindeer, bears, wolves and lemmings have been found together with those of Neolithic Man

The Nature Conservancy has also leased an area of 423 acres on the Isle of Purbeck which increases the Hartland Moor Reserve to 637 acres The extension is characterized by its fen type vegetation Black Bog rush occurs in the north-eastern part while sundews and bladderworts grow on the middle and lower bogs There are several local plants including the Dorset Heath along the bog edges The rest of the reserve consists of dry heathland

Wellcome Initiative

THE Wellcome trustees announced this week that they are proposing to allocate up to £2 5 million to medical scientists in universities in Great Britain and Northern Ireland, with the aim of encouraging more high-quality men and women to stay in Britain The new grants will enable medical research workers to continue their research programmes which might otherwise be threatened Letters have been sent to vice-chancellors in Great Britain and Northern Ireland asking them to inform the appropriate departments of the proposal Applications will have to be sponsored by the university concerned, and the final selection will be made by the Wellcome trustees Each grant will be allocated to meet the special needs of an individual and may be as large as £20,000 over a period of about five years

How Children Choose

OCCUPATIONS, and the factors which affect children's choices of subjects and careers, were both involved in the Dainton enquiry, because of their effect on the flow of candidates in science and technology into higher education To provide information on this subject a critical review was commissioned and has now been published (*Occupational Choice*, J R Butler, HMSO, 3s 6d) Mr Butler, a research fellow in sociology at the University of Manchester Medical Care Research Unit, has reviewed the literature which covers the formation of decisions on occupations in Britain, and summarizes the factors that appear to be most important Emphasis is laid on science and technology, because of the requirements of the Dainton enquiry, but non-scientific occupations had to be included in the investigations so that the influences working specifically towards occupations in science and technology could be picked out

The subject is approached from a sociological point of view, in so far as conclusions on occupational choice are assessed in terms of concepts which are linked with sociological or psychological theory, but the pattern of choice which emerges has practical significance Psychological, motivational, economic and sociological factors work together over a period of several years to predispose an individual towards a particular type of occupation, while his opportunities in other directions become limited by his education

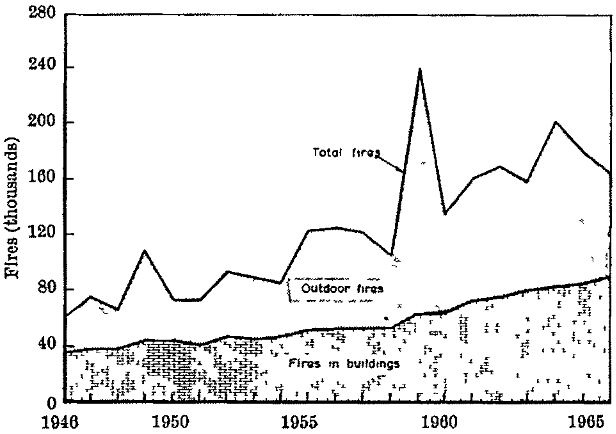
Scientific interests are often obvious as early as eight or ten, and by the mid-teens the choice between science or arts has usually been made. Because of the way the educational system is organized, revision of choice of occupation becomes less possible as an individual progresses up the school Although the specialized teaching helps those who have a definite career in mind, it has the disadvantage of setting limits on the choices of those who are uncommitted Thus the broad area of occupation is often decided early in the school career, while the final decision is a result of interactions between personal and external factors Personal interests and aptitudes are matched against ideas of the value set on various jobs, orientated towards people, extrinsic rewards or self-expression, external influences such as school, family and social contacts also have their effect The guidance of parents and friends is believed to be more important than more formal career advice received at school There are conflicting opinions about the effects on subject choices of personalities of teachers and the ways in which subjects are presented

Mr Butler's recommendations are put forward as guide lines for future investigators rather than as detailed research proposals He suggests that a multidisciplinary approach would provide interesting results, and recommends following the progress of a group of children from the age of eight until they enter the labour market To get the greatest value from such research a comprehensive theory must be developed to test findings An experimental programme of early and frequent vocational guidance to a group of children might yield valuable results

Incendiary Statistics

FIRES in Great Britain killed 780 people, three of them firemen, during 1966 This figure is in line with the increase that has, regrettably, been going on over the past six years, but does not reach the abnormally high figure of 818 which was recorded in 1963, the year of the hard winter Standing at 165,053, the total number of fires in 1966 was less than that for any of the three previous years, although the number of fires in buildings, 88,162, increased as it has done for the past 20 years The recently published *United Kingdom Fire Statistics for 1966* (HMSO, 15s) gives these figures, and statistical analyses by the Ministry of Technology's Fire Research Station, Borehamwood, of reports of fires attended by the 147 local authority fire brigades The statistics cover when, where and how fires were started, how they spread, and how they were fought Details of casualties are also given together with ways of escape of survivors, and correlations of casualties with sources of ignition of the fire

The number of fires in dwellings seems to be levelling off at about 34,000 a year, putting the rate of incidence at 20 fires per thousand dwellings at risk The rate of incidence in the distributive trades also appears to be levelling off, but in the manufacturing industries there is still an upward trend Outdoor fires have been fewer in the past couple of years, but the general trend since 1946 has been upward Refuse disposal is a particular problem, and fires from this source have more than doubled in the past four years Although these fires do not cause very much damage, they are expensive in terms of fire brigade time Smoking materials such as matches and naked lights caused 131 fatal fires, 25 per cent of the fatal fires from known causes. Electrical appliances and fires in grates each cause 19 per cent, and although children with fire caused only 5 per cent, this proportion is increasing. The number of incidents in which more than one person has died has been increasing over the past six years, and stands at 78 for 1966. Fires in buildings were more frequent in winter than in summer, while the reverse was true for fires not in buildings. The largest fire loss for a single month was estimated at more than £10 million, and the smallest at about £4 million. A computer was used for the first time to produce the 1966 tables and it is hoped that in future results will be produced more quickly.



Annual incidence of fires in the United Kingdom (from *United Kingdom Fire Statistics for 1966*)

Design for a Fusion Reactor

THE major problem of using nuclear fusion to produce power remains that of stabilizing a high temperature plasma for long enough for the reactions to produce a net gain of power. Although this has yet to be achieved, some rather speculative studies have been made of the engineering characteristics of fusion reactors. Mr R. Carruthers, Dr P. A. Davenport and Dr J. T. D. Mitchell of the Culham Laboratory of the United Kingdom Atomic Energy Authority have written the most recent of these, called *The Economic Generation of Power from Thermonuclear Fusion* (HMSO, 4*s* 6*d*.)

All, or almost all, designs for fusion reactors use magnetic fields as a means of keeping the very hot gases together. The authors of this report do the same, and suggest that the best geometry for the reactor is toroidal—doughnut shaped. The plasma, at a temperature of 7×10^8 °K, is contained in what amounts to a cylinder with the open ends joined to form a closed loop. The fuel used is a 50/50 mixture of deuterium and tritium. To get the reactor started, both fuels would be injected into the reactor, but once it was operating it would generate it own tritium in a blanket of molten salt surrounding the plasma. The blanket, containing lithium salts, would generate tritium by the Li(n,t) reaction, and would also act as a means of extracting the useful heat from the reactor. Thus the blanket would be circulated through salt pumps and heat extractors, and the lithium replenished. In this sense, the real fuels for the reactor would be deuterium and lithium.

The reactor chosen for the study is one of 5,000 MW (thermal), or 1,250 MW (electrical). The authors estimate that the capital cost of such a system would be between £68·5 and £74 per kW, the greater part of this (£29 per kW) being spent on conventional equipment, which includes the salt recirculating pumps, and the necessary electrical equipment. The second most expensive item is the superconducting magnet which would be used to keep the plasma in the right place, the reactor vessel and "blanket" would be reasonably cheap, only £4 per kW. On the basis of a 25 year life at 80 per cent load factor, and interest rates of 8 per cent, the generating costs of such a system would be 0·23 to 0·25 pence per kWh, of which the vast majority is attributable to the capital costs of the station. Fuel charges would be only 0·004 pence per kWh, and operation and maintenance 0·017 pence per kWh.

But the authors concede that there are a number of problems outstanding before this type of reactor can be built. The most obvious one, of course, is that of plasma containment, but there are others, the properties of the vacuum wall, for example, would need to be quite unusual. Fuel injection and exhaust extraction would also be a problem. It would even be quite hard to get the reactor started. For all that, the report is striking evidence of the continued optimism of those involved in fusion research.

Crystal Growing

THE Science Research Council has awarded a grant of £14,505 to Dr J. N. Sherwood, of the University of Strathclyde, Glasgow, to set up facilities for the growth of organic molecular crystals. Molecular solids are attracting a great deal of attention at present because of their uses in solid state devices. In particular, the electro-optical properties of many organic crystals suggest applications in radiation detectors—a familiar example is the use of certain aromatic phosphors in scintillation counters.

The electrical, optical and mechanical properties of these solids frequently depend on the structure of the material as well as its chemical composition. This is why there is a demand for high quality single crystals of organic substances.

Dr Sherwood will use the SRC grant to provide a crystal growing service for the universities and industry. This seems to be a desirable step. Crystal growing can require specialized equipment, and is frequently time-consuming. Because many research workers need only a few samples of the crystals they are studying, it is logical to have a laboratory with the facilities and the skill to provide the service.

Effects of Malnutrition

ONCE again the need to produce more food to keep up with trends in increasing population and changing social habits has been stressed. This time it is the joint FAO/WHO Expert Committee on Nutrition in its seventh report (published with two alternative covers as *WHO Tech. Rep. Series* No. 377, and *FAO Nutrition Meetings Rep. Series* No. 42).

The report reviews the state of knowledge in relation to nutritional requirements, and includes a discussion of various health problems which arise from malnutrition The consequences of infection are made worse by malnutrition Weanling diarrhoea, which is almost universal in developing countries, is caused by a combination of malnutrition and reduced resistance to infection in an environment with poor sanitation The committee recommends that the relationship between malnutrition and resistance should be investigated and stressed in the education of medical and public health workers

Iron deficiency is one of the causes of anaemia, and a programme of study initiated by WHO in 1961 is in progress to investigate this problem The contribution of factors such as loss of blood caused by hookworm infection is also being investigated Experiments with iron-59 have shown that iron from wheat is less readily absorbed than haemoglobin, ferritin or ferrous ascorbate, and people deficient in iron absorb less iron from wheat than do healthy people The committee recommends that, while such studies should continue, more emphasis should be placed on anaemia in infancy and childhood, times when it is possible that iron deficiency could cause irreparable damage to the blood and other tissues such as the gastro-intestinal tract Vitamin A deficiency is another serious problem, causing various diseases of the eye in infants and young children in Asia, Africa and Latin America In South and East Asia such diseases constitute an important cause of preventable blindness An effective preventive treatment for vitamin A deficiency is likely to be the enrichment of foodstuffs with the vitamin The committee recommends investigation of the stability of vitamin A in enriched foods, and the effects of cooking on its biological activity

Rickets, caused by vitamin D deficiency and lack of exposure to sunshine, is prevalent in many tropical and subtropical countries—in North Africa a WHO consultant found signs of the disease in between 45 and 60 per cent of children between birth and 5 years old It has been suggested that rickets influences infant mortality by lowering resistance to infections and aggravating the course of pneumonia and bronchopneumonia As measures to prevent rickets, the committee recommends supplementing breast milk with vitamin after the third or fourth month, treatment with vitamin D during the first 2 years of life as a public health measure, and education of mothers to expose their children to sufficient sunlight Daily administration of vitamin D will not be easy to achieve, and other approaches such as the use of periodic massive doses may be tried

Progress is also being made in the control of endemic goitre by the introduction of iodized salt to counteract iodine deficiency In the Himalayan endemic goitre belt there has been a striking reduction—from about 40 per cent to 15 per cent—in the prevalence of the condition in areas receiving salt fortified with potassium iodide or iodate

There is also some evidence that malnutrition in early childhood can adversely affect mental development, although there are so many complicating social factors that the results of intelligence tests are very difficult to assess in these terms The committee recommends that studies should be encouraged to assess the effects of malnutrition on mental development, learning and behaviour of young children, and that, when sufficient data have been accumulated, possibly within 5 years, an expert group should be convened by WHO to discuss the evidence

Alerting Chemists Quickly

It is becoming increasingly difficult for the information section of an organization to keep research staff informed of the literature Scanning journals for articles of likely interest to research staff, and attempting to keep up to date with their changing interests and projects, can put a great strain on the information staff While the ratio of information to research staff in the USA is 1 10, in Britain 1 30 is more usual, and 1 500 is not unknown Use of printed current awareness journals can help to some extent, particularly in small organizations or in those with restricted subject interests A new innovation is the use of computers for current awareness, providing what is known as a Selective Dissemination of Information service (SDI), that is, a service aimed at alerting research staff to material relevant to their subject interests The application of computers to SDI is only just beginning in Britain, but there are a few research programmes in progress now, and there is growing experience of the use of magnetic-tape outputs from large literature-handling services such as MEDLARS and Chemical Abstract Services

The main computer-based service operating at present is the Chemical Society Research Unit in Information Dissemination and Retrieval at Nottingham University supported by the Office for Scientific and Technical Information This unit is currently running searches (on a KDF 9 system) of the magnetic tape versions of *Chemical Titles* (*CT*), *Chemical Biological Activities* (*CBAC*) from the Chemical Abstracts Services, for a selected user population of more than 300 chemists Two other mechanized SDI services for chemists are those being run at the UKAEA laboratory at Aldermaston and the Shell laboratory, Sittingbourne These are also based on taped *CT* Outlines of these services, which are still in the experimental stage, were given by Mr L Corbett of Aldermaston and Mr P Gallagher of Sittingbourne at a meeting of the Institute of Information Scientists on March 13 Their talk was entitled, "Using Commercially Available Literature Tapes and 'Package' Computer Programmes for Current Awareness Services" Mr Corbett spoke of the advantages, limitations, potential and user reactions, and effects of the mechanized literature services operated at Aldermaston, and Mr Gallagher concentrated on features and problems of the programmes and machine operations

At Nottingham, the unit has developed its own programmes for the university's computer The Aldermaston and Shell services, however, use IBM 360/40 computers with the "1401 package" programmes of *CT* Experimental runs on issues of *CT* were begun at Aldermaston in 1966 Twenty issues have now been run The maximum throughput is 150 questions consisting of approximately 700 search words These have to be processed in two "passes" through the computer for each *CT* issue There are now more than 40 users of the service The machine time per issue is 1½–1¾ hours, and the number of references distributed is about 800 On the usefulness of the references or "hits" sent to users, Mr Corbett illustrated a sample analysis of ten questions Results of these showed an average relevance (precision) of 52 7 per cent The size of this figure is not as important in current literature alerting as in retrospective information retrieval It is in fact not desirable to have too narrow a field for current awareness—there should be room for "idea stimulating" information, developments in neighbouring fields, and so on The general relevance level of the references responded to (about 75 per cent) is 20 to 30 per cent, the average level for a question being about 35 per cent

Other "literature on tape" services were also discussed at the meeting Both Mr Corbett and Mr Gallagher spoke of the effects of SDI on the research staff, who certainly want it and like it Given a regular service, they show a tendency to alter and improve their "literature-use" habits individually and as "teams", this also applies to research/information staff communications

Defence Research

THERE was a mood of intense self-questioning in Britain about the national investment in research and development, Professor P M S Blackett told the Select Committee on Science and Technology on March 14 The dominant feeling was that the investment had not been wisely made, despite expenditures much greater than those in other countries, Britain's growth rate was slow But Professor Blackett was optimistic that now there was intense activity, centred on the Ministry of Technology, which would help to change all this The most important thing, he thought, was to persuade more scientifically qualified people to go into management—engineers were particularly important. "Historically we have failed to match management with technology," he said

Although the committee is launched on an investigation of the defence research establishments, it made little progress towards its objective in this session Professor Blackett's recent experience as an adviser to the Ministry of Technology and the cogent memorandum which he presented to the committee were both in the civil rather than the military field Often he frankly admitted that the questions were outside his competence In consequence, the session was spent in discussion of rather generalized notions of how Britain's economic performance could be improved Briefly, this meant a discussion of the twin doctrines of size and selectivity

In his memorandum, Professor Blackett provided a compelling argument in favour of large firms Since few firms can afford to spend more than 5 per cent of their turnover on research and development, it followed that a firm's turnover must be at least twenty times its research expenditure It was worthless to employ less than about five to ten qualified scientists and engineers, each of whom cost £10,000 a year to keep going For a team of ten scientists, then, the firm must have a turnover of £2,000,000 a year Without this, it would be unlikely to survive for long in a rapidly advancing technology, although if it were exceptionally lucky it might get along for a little while As for selectivity, Professor Blackett said that it was inescapable, because Britain had reached the limit of what could be done by broad fiscal means If the work of government laboratories was to be used, it had to be offered to one firm on the basis of exclusivity, or perhaps to two firms If the results were thrown open to all, nobody took them up, he said

Conservative members expressed some anxiety about this approach Sir Ian Orr-Ewing suggested that civil servants were not sufficiently well-equipped to make decisions of this sort Professor Blackett denied that the National Research Development Corporation or the Industrial Reorganization Corporation were part of the civil service As for the Ministry of Technology, there was a new section, concerned with industry, which he thought was well able to make these decisions And government purchasing power should also be more widely used as a selective mechanism It might be necessary to look at the whole company structure—exports, research and development structure, and the like—before awarding contracts This would mean that the Government would not always accept the lowest price offered

Parliament in Britain

by our Parliamentary Correspondent

Fuel Policy

MR ARTHUR PALMER and Sir Harry Legge-Bourke, both members of the Select Committee on Science and Technology, pressed the Minister of Power to make clear his policy on fuel Mr Palmer suggested that there were as many fuel policies as there were chairmen of nationalized industries, but Mr Marsh, Minister of Power, denied this He said that the Government's policy was not in conflict with the report of the select committee on the nuclear power industry in Britain, and that he and the Minister of Technology were both discussing this "large and important" document They hoped to come to Parliament soon with their conclusions

High Temperature Reactors

MR R FREESON, for the Ministry of Power, refused a request from Mr Eric Lubbock that he should direct the Central Electricity Generating Board to seek tenders for high temperature reactors for future power stations Mr Freeson said it was not a matter in which a general directive was appropriate Mr Lubbock asked sharply whether Mr Freeson was aware that the tender for the Hartlepools power station by the Nuclear Power Group, using a high temperature reactor, was several million pounds cheaper than the next quotation Was he also aware that electrical utilities in the United States published all details of tenders ? Mr Freeson said that these were matters for the CEGB

Dainton Report

MR PATRICK GORDON WALKER, Secretary of State for Education and Science, refused to be drawn on the subject of the Dainton report Mr Christopher Price, who asked the minister for a statement, wanted to know if he agreed that all children should study mathematics until they left school If so, he asked, where were the mathematics teachers to come from ? Mr Gordon Walker said that most of the recommendations of the report were directed at local authorities, universities and schools, and he did not think that he was yet called on to give a view But he said that he was having consultations with various bodies and associations concerned, and was gratified that "there has been a general acceptance that the swing away from science is wrong, and should be reversed" He would, he said, make a statement in due course

NEWS AND VIEWS

Magnetic-Faunal Boundaries

from a Geophysics Correspondent

EVER since Uffen (*Nature*, **198**, 143, 1963) suggested that removal of the geomagnetic field would produce an increase in ionizing radiation at the Earth's surface, thereby affecting the evolution of organisms, the problem of faunal extinction at field polarity transitions has rested in confusion Uffen's argument was essentially that, if during a geomagnetic polarity reversal the field strength passes through zero, the Earth will no longer be shielded from sterilizing cosmic rays, the Solar Wind and particles trapped in radiation belts These will then be free to bathe the Earth and thus produce drastic changes in mutation rates

Two years later, Sagan (*Nature*, **206**, 448, 1965) observed that even in the absence of the geomagnetic field, atmospheric absorption would remove most of the harmful radiation, but by this time Harrison and Funnell (*Nature*, **204**, 566, 1964) had discovered that the most recent reversal coincided with a faunal boundary in deep sea cores In the light of subsequent research we may now say that there is a close correlation between the Brunhes–Matuyama magnetic boundary and the χ–ψ Radiolaria boundary

Confusion arose through the conflict between Uffen's and Sagan's ideas together with a lack of precise knowledge of the magnitude of the radiation increase during a reversal, or the effect this increase would have on organisms In the past few months, three important papers have appeared independently, each of which indicates that faunal extinction cannot be related to known sources of radiation because the increase in such radiation during a field reversal is extremely small

In the first of these papers, Waddington (*Science*, **158**, 913, 1967) notes, after Sagan, that few primary particles impinging on the upper atmosphere will avoid nuclear interaction, and so any increase in radiation dose at sea level will be due entirely to secondary particles On this basis, he calculates that removal of the geomagnetic field will increase the secondary cosmic ray dosage by a maximum of only six mrad/year and the dosage of isotopes produced by cosmic rays and the Solar Wind by less than two mrad/year Each of these is negligible compared with normal background radiation Furthermore, there will be little or no increase in Antarctic latitudes, from which regions most of the deep sea cores exhibiting faunal extinction coincident with the latest reversal boundary have come The effect of the dumping of radiation belt particles will also be negligible because this process will occur only slowly as the magnetic field gradually weakens

In the third paper to appear, Harrison (*Nature*, **217**, 46, 1968) reaches essentially the same conclusions as Waddington In addition, however, he points to recent work of King and Kohl and of King-Hele and Allan, which indicates that certain meteorological phenomena may be partially controlled by the geomagnetic field The suggestion is that climatic change may be the causal intermediary between geomagnetic field reversals and faunal extinction, although Harrison admits that at the present time this hypothesis rests on insufficient evidence

The most impressive of the three contributions, however, is that of Black (*Earth and Planet Sci Letters*, **3**, 225, 1967) In an excellent paper, this author considers, quantitatively and in detail, the effects of cosmic rays, radiation from solar flares, the dumping of Van Allen belt particles, exposure of the Earth to the Solar Wind and the production of radioisotopes from the various radiation sources In each case, increased dosages during a polarity transition are shown to be negligible, and thus incapable of drastically affecting evolution—least of all, causing faunal extinction Even the increase in the concentration of ozone produced by the impact of the Solar Wind on the upper atmosphere is extremely small At least one source of climatic modification during a reversal is thus eliminated

In his conclusion, moreover, Black raises a significant general point He asks, in effect, whether there really is a causal magnetic–faunal boundary correlation In only one case, the Brunhes–Matuyama boundary, has a correlation been proved In a second case, the beginning of the Olduvai event, a correlation has been suggested by some workers but not confirmed by others Further, at least one of the faunal boundaries within the period covered by the last nine reversals lies away from any magnetic boundary If both the faunal and magnetic boundaries are distributed randomly in time, the probability of one coincidence within 10,000 years is ten per cent, but falls to one per cent for two coincidences Until a second correlation is confirmed, therefore, the first may only be a "coincidence" in the more colloquial sense of the word.

A DNA Restriction Enzyme

from our Cell Biology Correspondent

IN this issue of *Nature* (see page 1110) Meselson and Yuan report the isolation and partial purification, from *E coli* strain K, of an intriguing enzyme, endonuclease III K This enzyme can recognize and degrade foreign DNA introduced into the cell either as a bacteriophage genome or during abortive mating with another strain of *E coli* In other words the enzyme causes host and mating restriction by preventing infection of the cell with certain phages and mating with other *E coli* strains

When phages, such as λ, are grown in a particular strain of *E coli*, their DNA can be modified by modification enzymes in the host cell It seems that the modification enzymes methylate the phage DNA at specific sites When the phage reinfect a second cell of the same strain they replicate, but if they infect a different strain of *E coli* the phage DNA may be degraded by restriction enzymes like the one Meselson and Yuan have isolated These restriction enzymes probably recognize the pattern of methylation of DNA molecules If the introduced DNA has the same pattern of methylation as that of the host cell it is not degraded but if the pattern is different it is In one sense the DNA modification and restriction enzymes provide a recognition system analogous to an immune response which allows recognition of "self" from "non self"

Endonuclease III K requires ATP, Mg^{++} ions and, strikingly, S adenosylmethionine (SAM) SAM is a donor of methyl groups and because modification probably involves methylation of DNA it is possible that the one enzyme, endonuclease III K, can act either as a modification enzyme or as a restriction degrading foreign DNA molecules In this context, it is significant that Meselson and Yuan found that hybrid (heteroduplex) DNA molecules made with one strand from DNA of phage λ grown on *E coli* strain K (this DNA is not degraded by endonuclease III K) and the other strand from DNA of λ grown on *E coli* strain C (this DNA is degraded) are resistant to the restriction enzyme In order to function as a nuclease, endonuclease III K must recognize the pattern of methylation on both strands of the DNA molecule, if one is "self" and the other "non self", it does not function This, of course, provides an explanation of how the bacterial chromosome can replicate in a cell which contains endonuclease III K Because of semi-conservative replication, a newly replicated DNA molecule will be a heteroduplex in the sense that the parental strand will be methylated whereas the newly synthesized strand will not So the cell's restriction enzyme will be inhibited and this could allow time for the modification enzymes to methylate bases of the newly synthesized DNA strand at sites complementary to the methylated bases on the parental strand

Indeed, if endonuclease III K has both modification and restriction functions it is possible that the enzyme attaches to heteroduplex DNA, including the newly replicated DNA of the cells, completes methylation and then either degrades or leaves the DNA depending on the pattern of methylation

This, of course, is speculation, but Meselson and Yuan have already defined the chief characteristics of the restriction activity of endonuclease III K They proved that the enzyme is an endonuclease by showing that it digests circular λ phage DNA molecules As these have no ends, the enzyme must be an endonuclease attacking DNA molecules internally rather than at their ends The digestion product is double-stranded DNA with no single chain breaks In order to break double-stranded DNA, however, the enzyme first causes the scission of one of the two strands and then, a few seconds later, breaks the complementary strand either directly opposite or nearly opposite the first break They cannot say as yet whether one enzyme molecule catalyses the breakage of both strands or whether the two chains are attacked independently by two enzyme molecules However, the enzyme requires ATP, SAM and Mg^{++} ions for both double and single chain scission

New Insecticides

The Association of Applied Biologists held a symposium in the Natural History Museum on Friday, March 15, entitled "New Insecticides and their Application in Public Health and Industry"

The only new insecticides discussed were the synthetic pyrethroids, related to the natural pyrethrins, synthesized recently by Dr M Elliott and his colleagues at Rothamsted with financial assistance from the National Research Development Corporation The biological performance of these compounds was the subject of papers read by Mr A W Farnham (Rothamsted) and Mr J C Wickham (Cooper Technical Bureau) These compounds have been described elsewhere (*Nature*, **213**, 493, 1967, *Proceedings of the Fourth British Insecticide and Fungicide Conference* 1967, 437), but this was the first time that their biological properties have been critically presented

The synthetic pyrethroids, designated NRDC 104, 105, 106 and 107, were compared against several insect species with natural pyrethrins, other common insecticides and the other synthetic pyrethroids allethrin and 'Neopynamin' Their toxicities were found to be superior to all of these, and NRDC 107 (5-benzyl-3-furyl-methyl (+)-*trans* chrysanthemate) came out best of all Much time was spent comparing them with the natural pyrethrins, and particular reference was made to the fact that they are not synergized to the same extent, and do not knock down insects so rapidly It was, however, pointed out that synergism and knock down are not important in all fields of insect control These compounds should be investigated for applications where the properties of extremely high insecticidal activity and short persistence, coupled with complete safety in respect of mammalian toxicity, are desirable

Dr A S Hadaway (Ministry of Overseas Development) referred briefly to the interest which had been shown in these synthetic pyrethroids for vector control, and dealt with the large international operation being staged to find insecticides which would be suitable for the control of the vectors of tropical diseases and would replace DDT, to which may insects are now resistant The process of selection of insecticides from initial laboratory screening tests, through single hut and whole village trials, to large-scale epidemiological studies was outlined Emphasis was placed on the careful mammalian toxicity checks necessary, particularly during the field use of the insecticides

The remaining papers were concerned with the use of well-known insecticides for the control of pests of stored products Mr W Burns Brown (Pest Infestation Laboratory) discussed the growing interest in the use of phosphine for the control of insects in stored grain

This very effective fumigant is now available in a safe formulation that does not present a fire hazard when it is used New and interesting applications for dichlorvos were outlined by Mr A A Green (Pest Infestation Laboratory) and Mr E D Heath (Shellstar) It seems that although dichlorvos is no longer a new insecticide, new and safer ways of using it are being found A 1 per cent formulation in oil eliminates the hazard involved in diluting concentrates and the uncertainty of performance caused by hydrolysis in the water of aqueous formulations. This can be applied with safety by mist blowers and motorized knapsack sprayers

After these papers on new insecticides and on fundamental studies of the safer and more effective use of dichlorvos and phosphine, the audience was brought down to earth by the more mundane and essentially practical problems of infestation control Mr J Gradidge, deputizing for Mr R H Thompson (MAFF Infestation Control Laboratory), told of the trials and tribulations of ridding ships' holds, and government property, of vermin Buildings such as London Airport, which are in constant use and continuously illuminated, present special problems of insect control If the time spent in the final discussion is a guide, the problems of London Airport aroused the most interest of all the topics discussed during the day

Milk Production

from our Medical Biochemistry Correspondent

Babies in developed countries are no longer dependent on their mothers' milk, but for most of the world's population lactation is a matter of life or death for the baby. To the biochemist it is a fascinating synthetic process which produces a specific disaccharide (lactose), a specific protein (casein) and large quantities of fats All these activities are very rapidly "switched on" at birth and cease abruptly when lactation ends

The final step in the production of lactose is the reaction of UDP-galactose with glucose to form lactose and UDP This reaction is catalysed by the enzyme lactose synthetase, and Kuhn has now shown that, in rats, lactose synthetase activity increases very rapidly at birth and is probably the factor limiting lactose production (*Biochem J*, **106**, 743, 1968) There was no measurable lactose synthetase activity until 24 hours before birth, but if bovine α-lactalbumin was added the measured activity increased and there was some slight lactose synthetase activity before birth Studies of the lactose synthetase in milk have shown that it consists of two separable proteins, the *A* and *B* proteins. Tanahashi, Brodbeck and Ebner (*Biochim Biophys Acta,* **154**, 247, 1968) have recently shown that the *B* proteins from several species will react with bovine *A* protein to give an active enzyme, but only enzyme reconstituted with the *B* proteins from ruminants behaved like the normal bovine enzyme immunologically The bovine *B* protein is α-lactalbumin, and the stimulation of lactose synthetase in Kuhn's experiments may indicate that rat mammary gland has a relative deficiency of the *B* protein of lactose synthetase

Greenbaum and Pinder (*Biochem J*, **107**, 63, 1968) have studied the changes in activity of the enzymes synthesizing the nicotinamide nucleotides NAD and NADP during pregnancy and lactation in the rat Activity of the enzyme catalysing the synthesis of nicotinamide mononucleotide from nicotinamide (NMN pyrophosphorylase) and NADP from NAD (NAD kinase) followed the pattern found for many enzymes during pregnancy They were low on the tenth day of pregnancy, but increased fairly rapidly in the latter half of pregnancy and again at birth NMN pyrophosphorylase activity was high throughout lactation, falling sharply in the first two days of involution, but NAD kinase activity continued to increase in the second half of lactation when the NADP concentration increases Activity of the enzyme NMN adenylyltransferase which forms NAD from NMN appeared to be correlated with the occurrence of cell division rather than with coenzyme concentrations It was high at mid-pregnancy, rose slightly in the latter half of pregnancy and again doubled at birth The maximum activity was five days after birth, and the activity then fell steadily The authors think that this may be related to Morton's suggestion that the NAD concentration triggers cell division, while reduced NADP is needed for the synthesis of the fats in milk

Recent work on the synthesis of casein has shown that the lactating mammary gland must have arginase activity. Verbeke and co-workers (*Biochem. J.*, **106**, 719, 1968) showed that ^{14}C-ornithine was incorporated into the proline of casein through deamination of the ornithine to glutamic semi-aldehyde When ^{14}C-arginine was added to a solution perfusing an isolated lactating sheep udder, it was found that as much as 9 per cent of the proline in casein came from arginine The specific activities of plasma arginine, ornithine and proline indicated that the arginine was first converted to ornithine by arginase They did not, however, investigate whether arginase is always present or is rapidly synthesized at birth like lactose synthetase

Magnetic Storms

from our Magnetosphere Correspondent

A model of the magnetosphere known as the "reconnexion model" leads to the simple prediction that the southward component of the interplanetary magnetic field should be correlated with magnetic activity on the Earth Other models assume that the interplanetary magnetic field has no important effect on this activity The reconnexion model is based on the notion that interplanetary field lines can merge with terrestrial field lines On the solar side of the magnetosphere, field lines from the Sun go through the process of reconnexion near the neutral point, in such a way that interplanetary lines of force become connected to the polar regions of the Earth Because the Solar Wind sweeps lines of force from the polar regions into the tail of the magnetosphere, these interplanetary field lines later reconnect again on the night side of the Earth This has the effect of detaching the interplanetary field lines from the polar regions

Over the past few years, several tests of the prediction of the reconnexion model have been made using direct measurements of the interplanetary field from spacecraft The positive results found in all of them provide one of the most important reasons for the current wide acceptance of the reconnexion model Fairfield and Cahill (*J Geophys Res*, **71**, 155, 1966) made a detailed comparison with a small amount of data Wilcox and co-workers and Fairfield have also made statistical comparisons with the activity index

K_p. Recently Rostoker and Fälthammar (*J. Geophys. Res.*, **72**, 5853, 1967) made an extensive detailed comparison and, apart from clinching the close correlation, discovered a relation with the main phases of magnetic storms as well as the more common substorms seen by Fairfield and Cahill.

Rostoker and Fälthammar used hourly means of the interplanetary field and, because the duration of a typical substorm is about half an hour, the true correlation may be even stronger than the one they found. Main phases last several hours, and hourly means should be adequate for them, but it should be kept in mind that the interplanetary field can change completely several times in an hour. Rostoker and Fälthammar find that, for about 90 per cent of their cases, substorms are associated with a single hourly mean southward component of the interplanetary field of more than about $3\gamma (1\gamma = 10^{-5}$ G), while main phases are associated with two or more consecutive positive values, which need not be quite so strong. They also find that, when the recovery from the main phase is simple, it always occurs when the southward component decreases.

The study of magnetograms both from the ground and from space immediately shows a degree of complication comparable to meteorology, but, just as in meteorology there are some simple associations between kinds of weather and wind directions, there is clearly an association between magnetic storms and the southward interplanetary field.

Cell Wall Amino Alcohols

from our Microbiology Correspondent

LAST year, Tomasz (*Science*, **157**, 694, 1967) reported the occurrence of choline in the cell walls of pneumococci. The precise relationship of choline to the other wall constituents is unresolved, but it appears to be linked co-valently to teichoic acid or polysaccharide entities. The nutritional requirement of pneumococci for choline has been known for many years, but its discovery in cell walls, instead of in phospholipid, has allowed a number of physiological phenomena to be analysed. Tomasz and Mosser have discussed previously the requirement of choline metabolism for genetic "competence", the process whereby exogenous DNA is absorbed and the bacteria are transformed (*Proc. US Nat. Acad. Sci.*, **55**, 58, 1966). In the latest phase of this investigation, Tomasz (*Proc. US Nat. Acad. Sci.*, **59**, 86, 1968) has examined the effects of choline analogues on various cellular properties. The fate of both the mono- and di-methylamino derivatives and the parent member of the series, ethanolamine, has been followed and it seems that pneumococci are unable to methylate ethanolamine or the derivatives to choline. Although ethanolamine (EA), mono-methylamino ethanolamine (MEA) and di-methylamino ethanolamine (DEA) are incorporated into wall material, the physiological properties of the altered walls show a trend towards the normality of the choline-containing cells in the order DEA > MEA > EA.

An obvious effect of ethanolamine on pneumococci was the prevention of cell separation. Long chains of several hundred cells were produced, whereas in choline-supplemented media single and two-celled arrangements were predominant. Furthermore, stationary phase populations of EA-containing cells did not autolyse but remained stable for several weeks, "normal" cells autolysed within 20 h of the onset of stationary conditions. The autolytic enzyme system from choline-grown pneumococci was without action on the EA cells. Pneumococci are sensitive to low concentrations of deoxycholate and lysis follows this treatment; again, the EA cells proved to be resistant, although higher levels of the detergent adversely affected their viability. Perhaps the most interesting data relate to the incapacity of EA cultures to undergo genetic transformation—in other words, loss of competence. All of these abnormal properties could be removed by addition of choline, provided that the culture was still growing: deoxycholate sensitivity reappeared after 10 min, competence after 2 h and cell separation after about 6 h.

All aspects of choline and analogue incorporation into pneumococcal cells walls appear to be identical, which suggests that the amino alcohols are incorporated into a similar wall complex at a finite number of sites. The mechanism of the ethanolamine effects has not been elucidated. It may involve an all-inclusive primary effect inhibiting the action of the autolytic system, or a general disorientation of the wall components which disturbs several independent surface properties. The blocking of competency in cells containing EA is significant as the first unequivocal correlation between a primary wall structure and genetic transformation. Addition of the competence activator protein did not induce competence in the EA cells, neither did such cells produce the activator. Thus these EA-incompetent pneumococci are functionally analogous to the heritable incompetent mutants described previously by Tomasz.

Muscle Building

from our Molecular Biology Correspondent

UNTIL quite recently, the only tractable cell-free protein synthesizing system of mammalian origin was the reticulocyte. This had the great advantage of producing essentially one protein as the end product, which could be isolated and identified. Since then a few other systems have been made to function with reasonable efficiency, the limiting factor in general being the concentration of nucleases present in the tissue. One of the most satisfactory, by virtue of low nuclease activity, and because the ribosomes are not attached to a membrane, is chick embryo muscle. This was shown by Rich and his associates to produce myosin with high efficiency.

The same workers (Heywood and Rich, *Proc. Nat. Acad. Sci. US*, **59**, 590, 1968) now describe a spectacular experiment in which synthesis of the three most prevalent muscle proteins could be separately observed *in vitro*. This result stems from the observation that the extracted polysomes give rise to several populations in a sucrose density-gradient sedimentation. Four fractions were isolated, the heaviest consisting of polysomes made up of 50–60 ribosomes, the second of 15–25 ribosomes, the third of 5–9 ribosomes and the lightest of monomers and dimers. The first three fractions incorporated amino-acids with high efficiency. If it is now assumed that the polysomes are joined by intact messenger RNA, the length of the latter turns out to correspond roughly to the length of *m*RNA molecules specifying polypeptides of molecular weights equivalent to single myosin, actin and tropomyosin chains respectively. The inference was put to the test by examining the products of the cell-free systems stimulated by the four fractions. Non-radioactive muscle proteins were added as carriers, and the resulting material was examined by electrophoresis in polyacrylamide gel in a urea medium. It is to be expected that the results of such an experiment would be partly obscured by the presence of incomplete chains on the one hand, and of other muscle proteins on the other. Nevertheless, the product from the largest polysomes has its major component in the position corresponding to single myosin chains, the products from the other two populations of polysomes show some overlap, but it is clear that the first contains a prominent peak of radioactivity in the actin position, as well as two unidentified peaks, and the second contains two major peaks, one corresponding to tropomyosin and the other to one of the components that accompanies the actin. The final category of polysomes—monomers and dimers—gives no single recognizable product.

To strengthen their conclusions, Heywood and Rich applied the standard procedures for purification of myosin, actin and tropomyosin to the three products, diluted as before with carrier protein. In all cases the specific radioactivity followed the degree of purification. This strongly suggested that the products had been correctly identified. The final proof, as the authors recognize, will depend on chemical characterization—for example, fingerprinting—but the case is already strong.

A further interesting aspect is the change in relative concentrations of the different polysome populations which accompanies the development of the embryo: at ten days there is a preponderance of the actin polysomes with little myosin, at fourteen days a detectable increase in the myosin polysomes occurs and by eighteen days there is a large rise in the concentration of the tropomyosin group. This (as one by now expects) is consistent with morphological observations on the developing myofilaments: the thin actin filaments predominate throughout the early development, and only later do the Z-bands, in which the tropomyosin is thought to reside, become apparent.

Evidently then the protein sub-units are each synthesized under the control of a monocistronic messenger. This work must surely be seen as a most encouraging portent in the area of differentiation.

No Data on Sonic Booms

THE probability of serious material damage being caused by sonic booms of aircraft is very small so long as the aircraft are operated in a safe and normal manner. But with the current wholly inadequate understanding of the response of building materials to sonic boom pressure loadings it is just not possible to assess accurately what kinds and amounts of physical damage will occur. That is the conclusion of the report by the subcommittee on physical effects of the US National Academy of Sciences Committee on supersonic transport-sonic boom. The report was published on March 5.

The subcommittee set out to answer two questions: first, what kinds and amounts of physical damage might be anticipated from sonic booms which are "acceptable" to people and, second, what information is necessary to assess equitable compensation for any such damage. It found that the first question cannot be answered beyond saying that the damage is likely to be very small, because alarmingly little is known about the response of building materials to sonic booms or, for that matter, environmental parameters such as thunder claps, wind pressures and temperature changes. As a result the subcommittee has been principally concerned with how to collect more data. By far its most urgent recommendation is that instead of resuming overflight test programmes with supersonic aircraft, which cannot yield reliable and reproducible data because of uncontrollable atmospheric variations, at least two sonic boom simulators should be built immediately for controlled and reproducible testing of the effects of sonic boom forces. The simulators, one small and one large, should be capable of simulating the characteristic signature, the positive and negative pressures, the pulse duration and the rate of pressure rise and decay of sonic booms, ideally over a temperature range of − 65° F to + 150° F. The subcommittee recommends that about $300,000 should be spent over 2 years on this work exclusive of the cost of building the simulators. It is clear that until this is done there is no hope of establishing the cumulative effect of small pressure overloadings and the general failure criteria of potentially critical building materials.

Glass has already proved to be the most easily damaged building material. Furthermore, the manufacturers' data are apparently both inadequate and misleading for the analysis of sonic boom damage. The subcommittee therefore recommends an extensive investigation of the strength and responses of glass in the simulators. How the thickness of glass affects the probability of damage, whether or not the net boom overloading is the critical parameter, what effect various forms of mounting have and how the age of glass affects its response to sonic booms are a few of the questions that need to be answered. Apart from the straightforward tests, the report urges more theoretical research into glass failure and into the way the size, spacing and height of buildings influence constructive interference and reflexion of sonic booms.

It is not even clear how much glass is used in buildings. The subcommittee has called for a census of window panes, particularly in Albuquerque, Chicago, Dallas–Fort Worth and Denver—metropolitan areas which were subjected to sonic booms during the testing of the USAF aeroplane, the SR-71—and also Oklahoma City, where other sonic boom studies have been made. Censuses of other selected cities and towns would prove how climatic variation and city size affect glass usage. From the results of censuses it should be possible to plot the glass pane population of the United States and hence the best route for overflights.

Needless to say, not enough is known about the propagation of sonic booms, and the subcommittee urges, as a matter of high priority, the acceleration and expansion of the efforts of the Environmental Science Services Administration. ESSA has been working on the effects of atmospheric conditions on the sonic boom signatures of various aircraft recorded at ground level. This work should be expanded to include analysis of atmospheric and sonic boom data recorded at sites, especially urban centres, with different weather and topographical characteristics.

The subcommittee also calls for increased study of the effects of wind gusts and thunder claps, which in many ways resemble sonic booms, on buildings and building materials Such data ought to be useful in making realistic appraisals of the natural lifetime of structures likely to be damaged by sonic booms Under certain conditions booms might also cause failure of earth structures, such as coal tips and cuttings and foundations on unstable sand or clay strata So, as a matter of lower priority, the report suggests that small exploratory studies, both theoretical and in simulators, of earth structures should be made Apart from providing new information, these would provide some indication of the degree of potential danger

Anticipating the legal wrangles that are sure to follow regular overflights by supersonic aircraft, the subcommittee is concerned that not enough attention is being given to the problems of assessing progressive and incipient damage It points out that before any equitable law for adjudicating damage claims can be written, criteria are needed to assess claims for progressive damage that arises not from a single sonic boom but from the cumulative effect of many, and also for damage from incipient failures which would have occurred anyway with the next gust of wind The lawyers and civil engineers will have to put their heads together over this Furthermore, it may be necessary to set up a nation-wide sonic boom monitoring system to verify claims, to determine which aircraft was responsible and why it should have caused an excessive boom The subcommittee therefore recommends that a series of study contracts, worth $50,000 each, should be offered to competent companies so they can explore feasible monitoring systems and estimate their cost

The subcommittee is to be congratulated on its clear thinking and for making the ignorance of the effect of sonic booms so abundantly clear The US Government recently delayed the start of the Boeing supersonic airliner project by a year, and with luck many of the questions the report raises will be answered before that aeroplane comes into service In contrast, as far as can be gathered, Britain, which is pressing ahead with the Anglo-French Concorde, has so far made no systematic tests of the effects of sonic booms or any concise proposals of how such tests should be made. The Ministry of Technology coyly says some tests on the physical effects are in progress at the National Physical Laboratory and elsewhere, and the results of last year's test of public reaction to eleven sonic booms have yet to be announced

Drifting and Rifting of Africa

by

R. W. GIRDLER
School of Physics,
University of Newcastle upon Tyne

The development of the East African Rift System is related to the palaeomagnetic evidence for the continental drift of Africa.

RECENT studies of the East African Rift System have emphasized the need for looking at its evolution in terms of the continental drift of Africa There are two aspects for study first, the geometry of the rift system and, second, its evolution in time The East African Rift System extends from Zambia in the south to the Dead Sea in the north It is most well developed in the northern half, that is, the Red Sea and Gulf of Aden which is considered here.

Geometrical Considerations

One of the impressive features of the Red Sea which has been noticed for some time[1-3] is its symmetry This applies to the bathymetry, the gravity anomalies and the magnetic anomalies There is also further evidence that the youngest parts of the Red Sea and Gulf of Aden are along their centres For example, the accurately determined epicentres of earthquakes recorded since the introduction of the World Standard Seismograph Net (1963) for the Gulf of Aden and southern part of the Red Sea concentrate along their centres It seems that the centres of the Red Sea and Gulf of Aden are still active with crustal expansion still taking place Further, Vine[4] has re-interpreted the magnetic anomalies over the Red Sea in terms of the spreading sea floor hypothesis and this also requires symmetry with the newest crust in the centre

In addition to symmetry, it has been noticed[2] that the Red Sea and its various features widen towards the south and the Gulf of Aden widens towards the east This, with other evidence[2], has led to the suggestion that Arabia has moved northwards and rotated anticlockwise It is noted that the symmetry observations require that Africa has rotated clockwise

The structural evidence based largely on geophysical data is summarized in Figs 1 and 2 In Fig 1, the newest crust coincides with the largest magnetic anomalies In the Gulf of Aden, Laughton[5] suggests that widening took place in a north-easterly direction as indicated by the transform faults The transform fault movement has been confirmed by first motion studies of recent earthquakes[6] In the Red Sea, no transform faults have been found This does not mean that some might not exist A study of the topographic and geological maps suggests the possibility of a transform fault at about 19° N (Fig 1) Furthermore, it is clear from the dotted lines connecting both sides of the primary crack that there is a dominant N E -S W direction of movement This direction persists through the Red Sea to the Aqaba–Dead Sea rift where there is a possible transform motion of 90 km (ref 7)

Fig 2 shows a section across the Red Sea (15 5° to 16 5° N) incorporating the Vine interpretation of the axial magnetic anomalies with normally and reversely magnetized rocks becoming progressively older from the centre At this latitude, the anomalies extend over a reversal timescale just greater than three million years giving an average spreading rate of about 1 cm/yr Towards the north, the anomalies become progressively simpler until an anomaly associated with a single normally magnetized intrusion is found. The crack therefore developed in the south and spread northwards associated with the greater tension in the south and rotational movements

The Red Sea and Gulf of Aden are not exactly similar For the Red Sea, seismic refraction work[3,8] shows the presence of continental material on either side of the large, axial magnetic anomalies, whereas in the Gulf of Aden all seismic refraction profiles give oceanic structure[5,8] This includes a profile close to the Somali shore It is therefore possible that the amount of crustal separation in the Gulf of Aden may exceed the amount of separa-

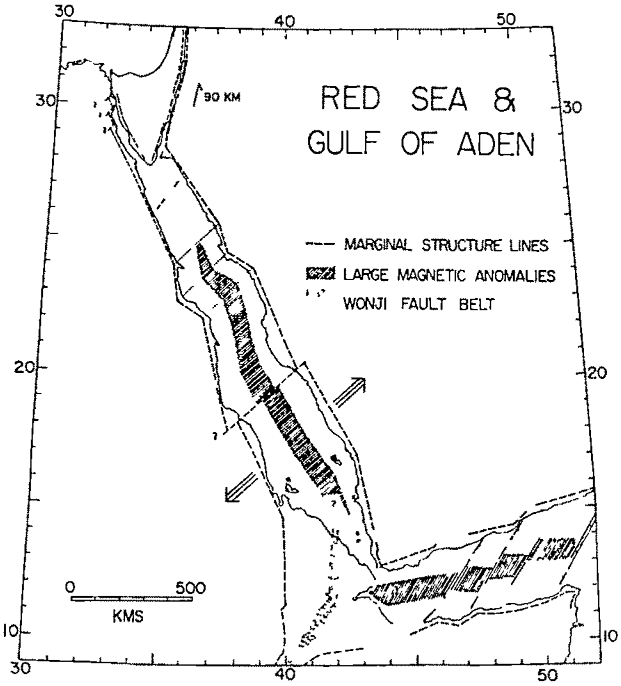

Fig 1 Map of the Red Sea and Gulf of Aden showing the possible movement of Arabia and Africa as inferred from transform faults and the interpretation of magnetic anomalies Mohr's Wonji fault belt in Ethiopia is also shown

tion in the Red Sea by a factor of three Because Arabia seems to have moved as one unit, this implies the horn of Africa must have moved clockwise further than the rest of Africa Further work in the junction area of the Red Sea and Gulf of Aden should help to solve this problem

Geological History of Rifting

This discussion suggests that the present activity has been proceeding for at least 5 million years Presumably the tensional stresses must have been in progress for much longer than this to cause sufficient crustal thinning to result in fracture and injection of igneous material

Geological evidence suggests that rifting has taken place in a series of phases For example, Baker[9] from his work in Kenya suggests a late Pleistocene phase which is still in progress (0–1 million years), a late Pliocene–early Pleistocene phase (? 4–2 million years) and a late Miocene phase (? 12–18 million years) Other workers[10] suggest several phases in the Miocene (the time of the Alpine orogeny) and an early phase of rifting at the end of the Cretaceous (about 70 million years). Evidence for rifting before this time seems to be controversial It seems that in most places the rift system has developed in a series of phases during the past 70 million years

The question now arises as to how these movements and phases of rifting are related to the continental drift of Africa For Africa most palaeomagnetic results are of particularly good quality First, many of the data are from igneous rocks and, second, in many cases the rocks are well dated radiometrically The data available covering the past 600 million years have been assembled using the original references where possible The pole positions have been computer checked and some minor discrepancies have been corrected

African Palaeomagnetic Poles

The recomputed palaeomagnetic poles for Africa are given in Table 1 Most of the ages are radiometric ages from the original references Where absolute ages are not available, such as for sedimentary rocks, they have been estimated from the Geological Society of London Phanerozoic time-scale[30] In each case the latitude and longitude of the palaeo-north pole is given together with the polarity of the rocks The method of computing mean poles from site mean poles has been preferred where the data are available Nearly all the data are from rocks which were subjected to a c or thermal demagnetization The data from rocks not so treated (included to fill large gaps in the time-scale) are marked by an asterisk

The best polar wander curve, using poles only from treated samples, is shown in Fig 3 The poles may be considered in three groups (*a*) The poles for rocks less than 50 million years old spread from a position close to the present axial dipole to a position 73° N. 145° E , most of them being to the east of the Greenwich meridian (*b*) The poles for rocks with ages ranging from 110 to 260 million years form a tight cluster with a mean at 64° N , 101° W , and circle of confidence[31] $\alpha_{95} = 4\ 6°$, suggesting that there was no continental drift of Africa and no polar wander during this period (*c*) The few results available for rocks older than 250 million years suggest there were phases of large scale continental drift and/or polar wander from 250 to 550 million years.

Palaeolatitudes of Nairobi

For some purposes, such as relating the drift of Africa to rifting and other aspects of geological history, it is more convenient to express the palaeomagnetic results in

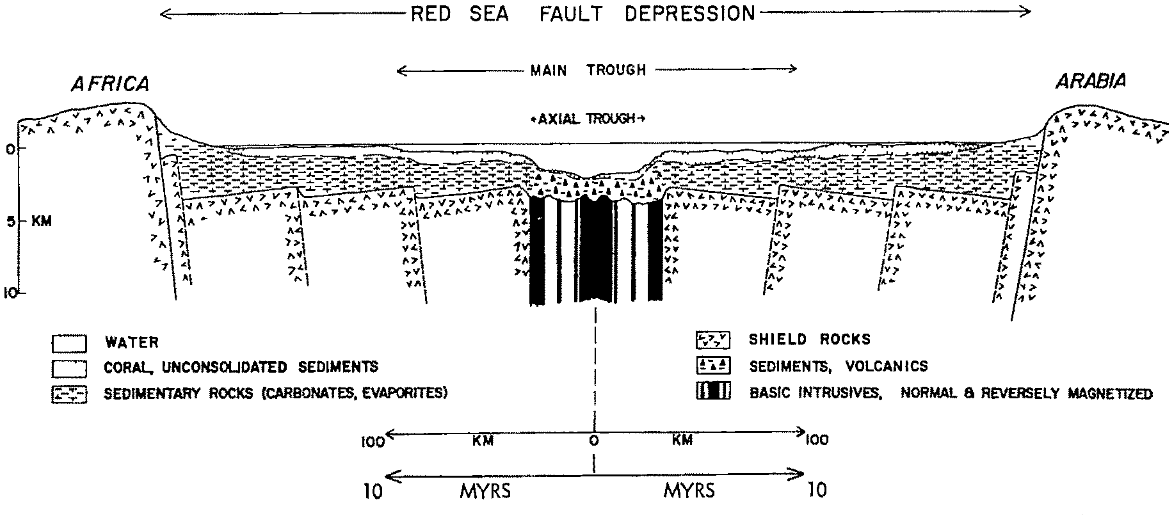

Fig 2 Structural section of the southern part of the Red Sea modified after Drake and Girdler (1964) and incorporating Vine's interpretation of the axial magnetic anomalies The igneous rocks in the axial zone have been intruded progressively over the past 3 to 4 million years

Table 1

Age (million years)	Rock type	Polarity	N Pole	Az	Lat.	Ref
< 2	Kenya trachytes	R	77 1° N , 127 1° E	+13°	2° S	11
1 8	Olduvai basalts	N	84 7° N , 101 0° E	+5°	0°	12

Az , palaeodeclination of Nairobi +, measured clockwise from present north, −, measured anticlockwise from present north Lat , palaeolatitude of Nairobi

* May be unreliable because of lack of cleaning or incomplete information

terms of palaeolatitudes and palaeoazimuths Fig 4 shows the palaeolatitudes of Nairobi computed from the poles of Table 1 It is seen that the site of Nairobi has moved fairly rapidly north from 20° S during the past 110 million years During the period 110 to 250 million years ago the palaeolatitude was constant at 20° S Before this time, there was a rapid movement of Africa across the polar regions to about 25° to 30° S some 400 million years ago Such a movement across the polar regions is consistent with the evidence for the existence of glaciations in the Permo-Carboniferous (about 300 million years ago)[32,33]

The orogenic revolutions of Holmes[34] are also shown in Fig 4 along the same timescale. It is seen that the time interval from 110 to 250 million years was a particularly quiet time in the Earth's history The correlation of this part of the two curves is so good that it is tempting to extrapolate the palaeolatitude curve and suggest that Africa remained in the same position from 250 to 70 million years ago The two phases of rapid continental drift of Africa occur at the same times as the Hercynian and Alpine orogenies It is during the latter northward movement of Africa that the development of the East African Rift System was most impressive

Palaeoazimuths Rotation of Africa

The palaeo-declinations or azimuths for Nairobi have also been computed and included in Table 1 The azimuths and rotation of Nairobi are presented in diagrammatic form in Fig 5 In order to gain a representation of the way in which Nairobi has rotated, the azimuths have to be plotted with opposite sign

For the past 50 million years, eight of the nine declinations range from 0° to +16° (that is, east of north) and for clarity smoothed values are plotted in Fig. 5 It is seen that there is some suggestion of a change in direction of rotation of Africa some time between 5 and 15 million years ago, from anticlockwise to clockwise This is consistent with the interpretation of the magnetic anomalies over the Red Sea which suggests that the last phase of the development of the Red Sea was associated with the anticlockwise rotation of Arabia and clockwise rotation of Africa.

The azimuths for the period 110 to 250 million years are shown by the shaded zone, there being no significant differences for this period By analogy with Fig 4 it seems likely that the azimuth of Nairobi (N 19° W) remained constant from 250 to 70 million years ago when Africa began to rotate anticlockwise and move northwards

Because Africa crossed the polar region some time between 300 and 400 million years ago (Fig. 4), the azimuths for this interval are liable to large errors After crossing the pole the azimuths become "reversed" This does not, of course, imply a 180° rotation of the continent Because of this, the azimuths for 500 and 550 million years are shown separately

Does Polar Wandering Exist ?

These observations cast doubt on the existence of polar wandering First, from the African palaeomagnetic results, it seems there was no appreciable polar wander for at least 140 million years and maybe for 180 million years (from 250 to 70 million years ago) Second, the tentative agreement between the movement of Africa as required from palaeomagnetic results and structural arguments (for example, the symmetry of the Red Sea and Gulf of Aden) suggests that continental drift is sufficient to explain the palaeomagnetic results The possibility, however, of polar wandering synchronous with, or following, continental drift due to redistribution of mass on the sphere, is not excluded (the wandering beetle of Gold[35,36]) The palaeomagnetic results are not sensitive enough to resolve this possibility

Implications for Mantle Convection Theories

The large-scale movements of Africa (before 250 million years ago and from 70 million years ago to the present)

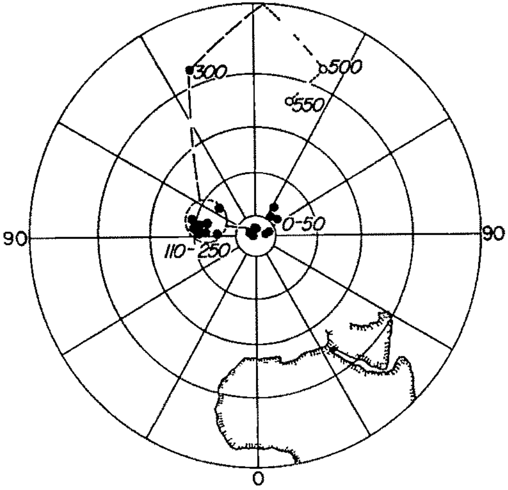

Fig 3 Provisional polar wander curve for Africa The circle groups the poles from rocks 110 to 250 million years old and is not a circle of confidence During this period the pole was relatively stationary

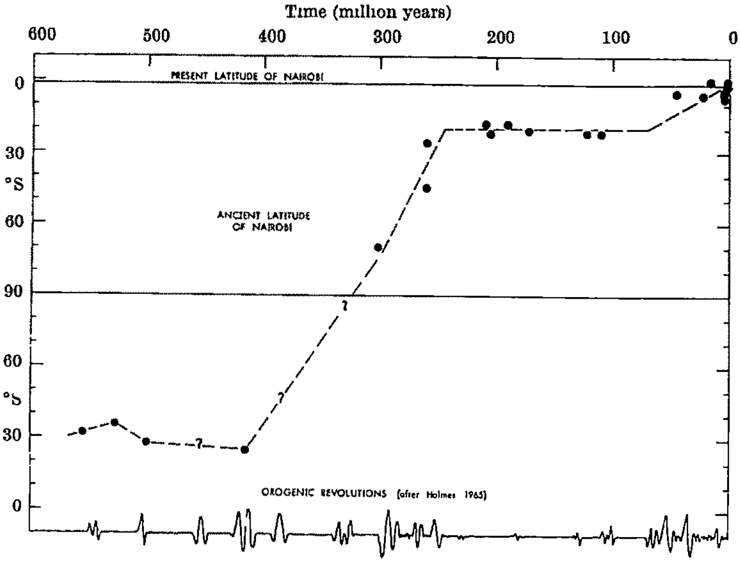

Fig 4 The palaeolatitude of Nairobi Africa crossed the polar regions about 300 million years ago Before 300 million years, there is a shortage of reliable data From about 250 million years to possibly 70 million years ago, Africa was stationary There were at least two phases of drift coinciding with the Hercynian and Alpine orogenies respectively

support the existence of some kind of convective motion in the mantle The fact that Africa remained stationary for at least 140 million years suggests two possibilities either the mantle convective motion stopped some 240 million years ago and restarted some 70 million years ago or Africa was conformably seated in an equilibrium position and the convection pattern changed about 70 million years ago The possible change in direction of rotation of Africa about 10 million years ago suggests the possibility of a further sudden change in the convection pattern at about that time

The available palaeomagnetic results make possible the following conclusions for the history of the African continent over the past 600 million years (1) From 600 to 300 million years there is a shortage of data. The palaeolatitude of Nairobi from 550 to 410 million years was about 30° S and at 500 to 550 million years the palaeoazimuth was 110° to 125° . (2) For a period just before 300 million years to about 250 million years ago, there was rapid continental drift when Africa passed across the polar regions (3) From 210 to 110 million years and possibly from 240 to 70 million years Africa was stable (no drift and no polar wander) The latitude of Nairobi was 20° S and the palaeoazimuth was N 19° W (4) During the past 70 million years, Africa moved north again and rotated anticlockwise, Nairobi changing latitude from 20° S to its present latitude of 1 3° S It was during this time that the East African Rift System developed probably in phases (5) There is some evidence for a change in direction of rotation of Africa from anticlockwise to clockwise during the past 10 million years or so This is consistent with the symmetrical development of the Red Sea and Gulf of Aden (6) The data raise doubts about polar wandering but cannot exclude the possibility of polar wandering during periods of continental drift

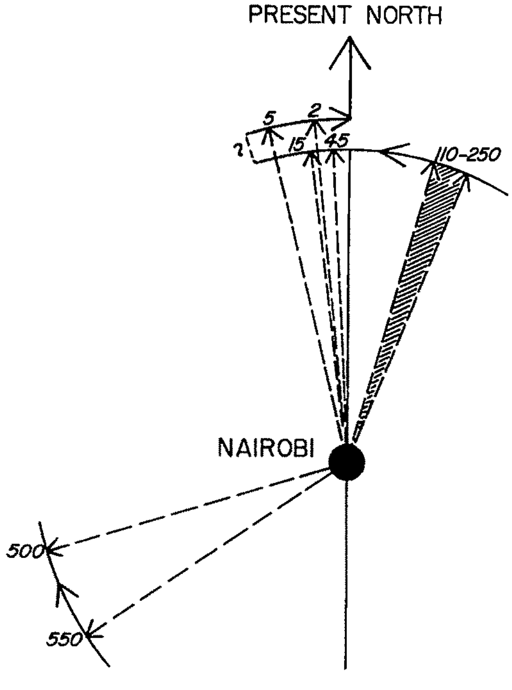

Fig 5 Palaeoazimuths and rotation of Nairobi The palaeoazimuths of Table 1 are plotted with opposite sign so as to give some representation of the way in which Africa has rotated During the past 70 million years Africa rotated anticlockwise and over the past 10 million years or so may have rotated clockwise

Since this work was carried out, two relevant papers have appeared[29,37] Ewing and Ewing[37], in their studies of the distribution of sediment on the ocean floor, have found a paucity of sediments over the central parts of the ocean rift system At a distance of 100 to 400 km from the ridge axes, they find an abrupt or discontinuous increase in sediment thickness On the spreading sea floor hypothesis, this increase is found in all cases to occur at approximately 10 million years This favours the idea that the sea floor restarted spreading about 10 million years ago after a quiet interval The Red Sea and Gulf of Aden are in continuity with the mid-ocean ridge system, so it is reasonable to conclude that the last phase of opening of the Red Sea and Gulf of Aden commenced at about the same time Briden[29] finds that drift in phases may apply to the other southern hemisphere continents and suggests there were at least four episodes of drift of Gondwanaland

Evidence seems to be accumulating in support of long quiet periods of Earth history with relatively sudden phases of activity, continental drift and mountain building. Within these active periods, there were shorter periods of quiescence and activity. The shorter timescale periods of activity produce phases of sea floor spreading and rifting such as we are experiencing today

I thank Mrs Marion Russell for computer checking the palaeomagnetic data and various members of the School of Physics, University of Newcastle, for helpful discussions

Control of Growth in Two Populations of Elephant Seals

by

M. M. BRYDEN*

Growth models can explain differences in growth patterns and time of onset of puberty in elephant seal populations at Macquarie Island and Falklands Islands. Elephant seals at Macquarie Island are permanently stunted—possibly because of retarded growth during the suckling period.

It has been said that gigantism in whales is an indication of over-specialization, and it can be developed to the degree in which it now occurs only in an aquatic mammal completely emancipated from the land, because in water the weight of the whale is counter-poised by the weight of water it displaces[1]. Whales washed up on beaches often die after collapse of the rib cage[2], which is not sufficiently strong to support, in air, the weight of tissue surrounding it. "The elephant [seal] ... now seems to be at the critical point in this regard. Some increase in size ... would likely render it unable to leave the water"[1].

The control of mature size in the elephant seal (*Mirounga leonina*, Linn.) seems to be most important for its survival. Although adapted for an aquatic life, it still hauls itself out onto land to breed and moult. Its structure must therefore be adequate to withstand the effects of gravity in spite of the fact that most of the annual cycle is spent in the sea.

Differences in the growth patterns of elephant seals at Macquarie Island and the Falklands Islands have been observed[3,4]. Macquarie Island seals have a slower rate of growth, later onset of puberty and smaller mature size than elephant seals of the Falklands Islands Dependencies. Elephant seals on Heard Island are also known to be smaller than those of the Falklands Islands[5]. Even though Lydekker[6] proposed the existence of several subspecifically distinct groups of elephant seals in the Southern Ocean, there is still no real justification for the recognition of such sub-species[7]. There is no justification therefore in assuming that the different growth and reproductive patterns of elephant seals at the different localities are caused by genetic factors, and the possibility of limitation of food supplies being associated with slower rate of development and delay of puberty of elephant seals at Macquarie Island and Heard Island has been dismissed[3].

I propose to explain, in terms of models proposed by Dickinson[8] and Tanner[9], possible reasons for the differences in growth and age at puberty of elephant seals at the different islands.

A hypothesis of mammalian growth, proposed by Dickinson[8], is represented diagrammatically in Fig. 1. The hypothesis has two limits to the growth curve, a maximum growth path permitted by a "juvenile growth potential", and a minimum growth path conforming to the genetic growth competence. In Fig. 1, the minimum growth curve represents the boundary between growth which reaches a normal end point, and abnormal growth which fails to reach the normal end point. The juvenile growth potential controls the maximum growth path which can occur when nutritional and other environmental conditions are good. When the maximum growth path is followed, variation in size as a result of growth competence is obscured until maturity, by other factors influencing the utilization of nutrients present in excess of the genetically controlled requirements. Dickinson[8] postulated that genetically the juvenile growth potential is unrelated to the genetic growth competence.

The application of this hypothesis to this study is shown in Fig. 2. It is seen that because of the very rapid growth rate of elephant seal pups from birth to weaning, any retardation of growth during this short suckling

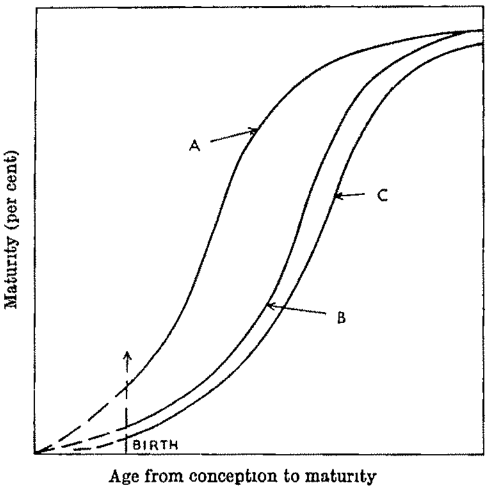

Fig. 1. Diagram illustrating Dickinson's hypothesis of mammalian growth[8]. *A*, Growth path making maximum use of juvenile growth potential; *B*, minimal growth path conforming to genetic growth competence; *C*, permanent stunting on a subminimal environment.

---

* Present address: Department of Anatomy, New York State Veterinary College, Cornell University, Ithaca, New York.

period, shown to occur in Macquarie Island elephant seals[4], will have a profound effect on the remainder of the growth of the animal, if this retardation causes the growth curve to fall below the minimal growth path conforming to the genetic growth competence. The Falkland Islands elephant seals (F I) are most likely following a growth path which approaches that making maximum use of the juvenile growth potential, whereas the elephant seals of Macquarie Island (M I) probably follow a growth path on which there is permanent stunting as a result of subminimal environment during the suckling period.

Laws[10] demonstrated a close relationship between the attainment of a certain body size, and the onset of puberty in pinnipeds. Assuming that a certain minimum body weight must be attained before puberty is reached in elephant seals, the model explains the later onset of puberty in elephant seals at Macquarie Island (Fig 2).

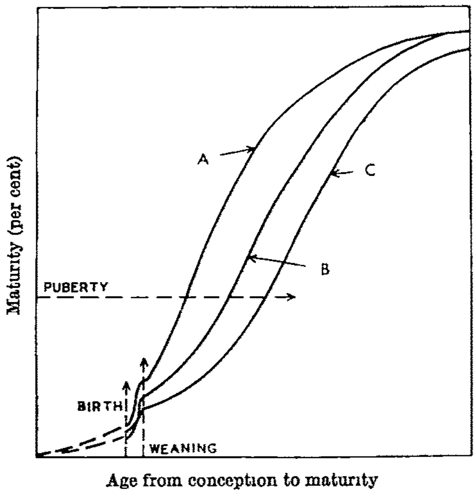

Fig 2 Application of Dickinson's model to the present study. *A*, *B* and *C* as in Fig 1

The growth path followed by Macquarie Island elephant seals resulting in permanent stunting is derived from Dickinson's hypothesis. This hypothesis, however, does not explain the physiological mechanism involved. The mechanism can be explained in terms of the model of growth postulated by Tanner[9]. In this model a time-tally mechanism, located somewhere in the brain—most likely in the hypothalamus—is envisaged. It is suggested that this mechanism is responsible for the recognition of, and interaction with, a growth inhibitor substance produced by the cells of the body. The example was given of experiments[11,12] in which rats poorly fed during the first 21 days after birth never caught up afterwards with their littermates' growth. In terms of Tanner's model, the malnutrition occurring while the brain was still growing relatively rapidly apparently resulted in permanent damage to the time-tally mechanism. Circumstantial evidence is available in support of this model. Schinckel[13] produced an approximation from results in the literature which indicated that the sensitivity to permanent stunting of lambs was most marked during late foetal life and the first few weeks only of postnatal life, and Fox[14] reported that the most dramatic structural changes in the brain of the dog during postnatal growth occurred between 2 and 4 weeks of age.

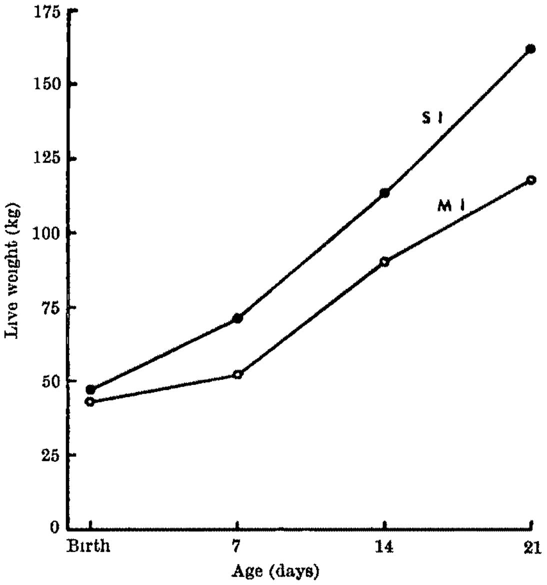

Fig. 3 Comparison of growth of elephant seal pups from birth to 21 days old at Macquarie Island (M I) and Signy Island (S I) (the latter after Laws[15])

The growth curves of elephant seal pups at Macquarie Island and Signy Island (the latter from Laws[15]) are shown in Fig 3. The birth weight of Macquarie Island pups is only slightly lower than that of Signy Island pups (and may not be significantly different[4]), but there is a very much greater difference in weights at weaning, which can be attributed, at least in part, to interference to suckling of Macquarie Island pups by disturbances in the harems[4]. Here then is a natural situation similar to that produced experimentally in rats by Widdowson and McCance[11] and Widdowson and Kennedy[12].

The growth curves of nutritionally independent elephant seals at Macquarie Island and the Falkland Islands Dependencies are shown in Fig 4. The Macquarie Island seal growth curves were made up from my own data; those of the Falkland Islands seals were obtained by fitting body length measurements to a weight–length curve[7].

Figs 5 and 6 show the growth of the brain of elephant seals during the suckling period, and brain growth after weaning. In females 24 per cent, and in males 15 per cent, of postnatal brain growth occurs during this approximately 3 week suckling period. Retardation of pups' growth therefore during this stage of their life must affect the growth of the brain to a considerable extent, even allowing for the fact that the brain has a high

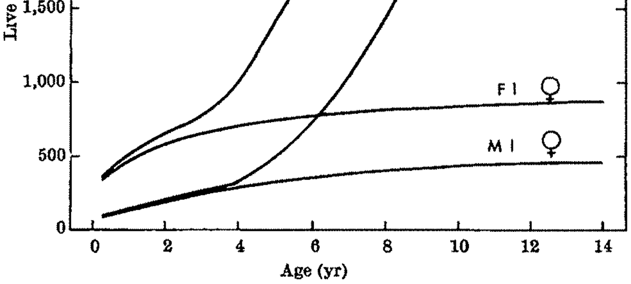

Fig 4 Postweaning increase of live weight of elephant seals at Macquarie Island (M I) and the Falkland Islands (F I). The Falkland Islands curves were drawn by fitting body lengths to a weight–length curve (Laws[7])

priority for growth The reduction in growth of suckling pups at Macquarie Island while their brains are so actively growing could result in permanent damage to the postulated time-tally mechanism

Comparison of body weight figures of mature animals at Macquarie Island and at the Falkland Islands (Table 1) indicates that mature elephant seal males at Macquarie Island are 94 per cent of the size of mature males at the Falkland Islands Mature females at Macquarie Island are only 60 per cent of the size of those on Falkland Islands The size of mature males, however, is difficult to compare, and the comparison is only approximate because sealing operations at the Falklands Islands Dependencies selectively remove the largest bulls, and it is unlikely that the full potential for growth of males is realized at this locality[7] In the light of Howell's statement[1] the possibility arises that, with the relief of social pressures caused by the sealing operations, some of the male animals may reach a size which would prevent them from living and moving comfortably on land should they reach full size

Table 1 COMPARISON OF MATURE WEIGHTS OF ELEPHANT SEALS AT MACQUARIE ISLAND AND THE FALKLAND ISLANDS DEPENDENCIES

	Mean weight (kg)	
	Macquarie Island	Falkland Islands*
Mature males	3,000	3,200
Mature females	400	680

* Weights derived by fitting body lengths to a weight–length curve[8]

It is seen from Fig 4 that Macquarie Island seals, which have been retarded early in life, grow very slowly after weaning, but they never catch up with the Falkland Islands seals This agrees with the model shown in Fig 2 Age at onset of puberty, greater in Macquarie Island than in Falkland Islands seals[3], seems to be related to attainment of a certain body size This also seems to agree with the Fig 2 model The age of onset of puberty of Macquarie Island seals is also more variable This is probably closely related to the greater variation in growth rate of these animals This supports the assumption that onset of puberty in the elephant seal is associated with the attainment of a certain minimum body size, which occurs more rapidly and with less variation in the faster and more uniformly growing Falkland Islands seals In a comparative study of growth in body length of various families of seals[16], it was shown that the slower growing species tended to take longer to reach a size necessary for reproduction (about 87 per cent of final body length) and so mature later This is most likely to occur within, as well as between, species

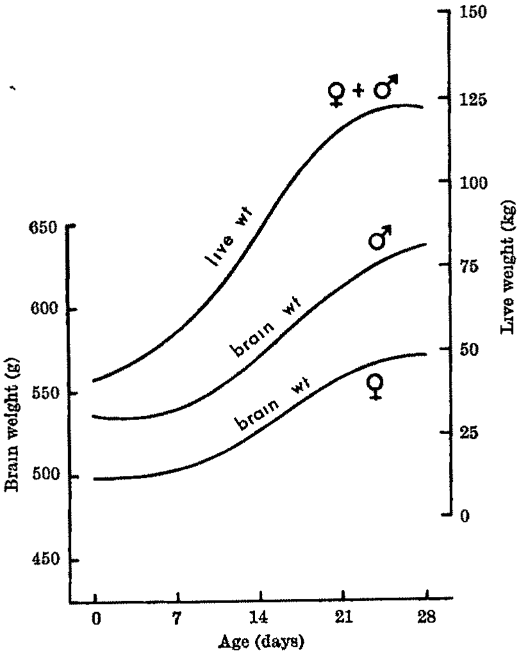

Fig 5. Increase in brain weight and live weight of elephant seal pups during suckling at Macquarie Island.

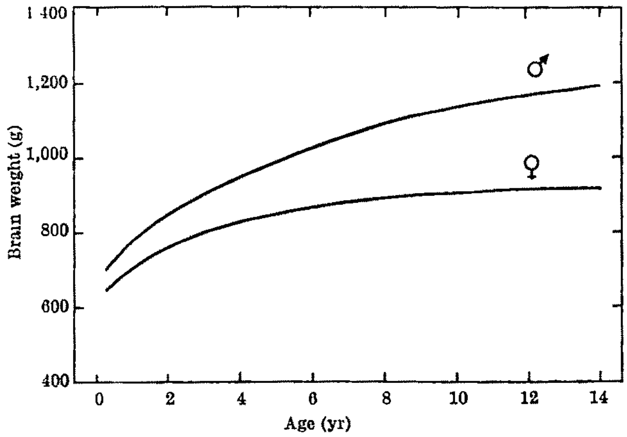

Fig 6 Postweaning increase in brain weight and live weight of elephant seals at Macquarie Island

Brody[17] has shown that puberty is associated with the attainment of a certain size, which corresponds to the point of inflection of the growth curve The latter occurs at over 60 per cent of the mature weight in man, slightly below 60 per cent of the mature weight in chimpanzees and about 30 per cent of the mature weight in laboratory and farm animals From the figures available from the Falkland Islands and Macquarie Island, it appears that puberty in elephant seals occurs at about 30 per cent of the mature weight in males, and at about 55 per cent in females, which corresponds to approximately 4 yr and 2 yr of age respectively in male and female Falkland Islands seals[18], and 5 to 8 yr and 3 to 5 yr respectively in male and female Macquarie Island seals[3]

The growth models offer an explanation of the difference in growth pattern from birth to maturity, different mature size and reproductive pattern of these two populations of elephant seals, and of the mechanism by which these differences are brought about, as a result of a difference in growth during the first three weeks of postnatal life Reduction in size of mature females most likely leads to depressed birth weight of pups as with other mammals[19]. This could further reduce postnatal growth if birth weight should fall below the minimum growth path conforming to the genetic growth competence

In this highly adapted aquatic species, it is apparent that the terrestrial part of the annual cycle which has been retained has an important effect on the total life history, particularly with regard to growth and reproduction

These observations were made while I was a member of the Australian National Antarctic Research Expeditions at Macquarie Island, 1964–66.

Computers and Employment

A recent conference in West Germany discussed the effects of advancing technology on employment. Professor L R. B. Elton, of the Institute for Educational Technology at the University of Surrey, a participant at the conference, has prepared the following report.

FOR some years now, the German Metalworkers' Union (I G Metall) has concerned itself with the problems and opportunities that automation and technological progress are bringing to the worker and to the community This month, Dr G Friedrichs, director of the division on automation of I G Metall, organized the third large international conference in this field, this time on the subject of computers and employment, with special reference to the employment of technicians and other non-manual workers It took place at Oberhausen in the heart of the Ruhr and was attended by more than 1,000 delegates of whom about 130 came from 22 foreign countries, including the United States and the USSR Of the 33 main speakers, three were ministers of the German Federal Government and two were high international officials The rest were divided between academics, employers, workers and trade union officials

It is probable that nothing much was said at the conference that in one way or another was not known before We heard about the computer explosion, particularly in the United States, and the effect it is having on the employment of workers and operatives Surprisingly, perhaps, the effect at the technician level has been much less pronounced This may well be because the advent of a computer in an organization is at first likely to increase the need for technicians, and that at present computers are used mainly for data processing Once they are used widely for the solution of engineering problems and problems of design, technicians too will face the need for re-education and re-deployment On the whole, however, Arnold Weber, professor of industrial relations at Chicago, was reassuring and felt that automation would lead to a redistribution of employment, which could be manageable This presupposed, however, a generally healthy economy, planned programmes to deal with the problems of shifting workers from one job to another, and a general support and expansion of education

The need for more and wider education was a recurring theme of the conference and the one that created most passion Again and again it was stressed that this education had to be general, particularly in mathematics and in the basic sciences, in order to make subsequent re-education possible It was interesting that, compared with educational concerns, economic ones seemed to fade into the background as the conference proceeded It is clear that none of the European countries have found a satisfactory way to combine education and training for those who have left school, and the American solution—to leave students in full-time education for as long as possible through the creation of junior colleges —is not likely to prove economically viable in any other country Whether it is educationally sound was not discussed

The structure of the German system of secondary education came in for some hard knocks At present it is not unlike the tripartite system that was instituted in this country through the 1944 Act, and it was clear that the trade union members of the conference were much in favour of a change towards the comprehensive school The employers' side seemed decidedly less enthusiastic for change On the other hand, when it came to content, the recent proposals of the Dainton Committee would merely bring Britain into line with German reforms of the past few years, which have approached the problem of the swing away from science from the point of under-specialization An unfortunate consequence of the German reform appears to be that science in the upper school has lost ground in the curriculum compared with the study of languages. The point that a general education in mathematics and science should be part of the curriculum for all for as long as possible was again stressed in a televised discussion on further education and re-education, in which representatives of the Netherlands, Czechoslovakia, Hungary, West Germany and Britain took part In this discussion, the demand of the I G. Metall for sabbatical re-education leave for all as of right received qualified, although sympathetic support, but it was accepted that more could not be expected from employers Employers would, of course, provide courses which were in the direct interests of their concerns, but any wider forms of re-education—and it would have to be wide to be effective—would have to come through government action. In this connexion the flexible approach of the British technical college received praise

Another theme that received much attention was the division between white collar and blue collar workers In the Netherlands this division seems to have largely disappeared, and contributions from both the United States and the United Kingdom stressed that, in the logic of the situation, the divisions are decreasing and will eventually disappear everywhere. But this does not mean that there are not difficulties on the way, and much discussion centred on the problems of those employeers who are not members of a trade union, and are faced with rapidly changing employment conditions, including shift and piecework. Difficulties of a different kind, that face a small socialist country trying to liberalize both its economy and its society, were discussed in a very frank report by Professor Levčik of Czechoslovakia

An outstanding and forward looking contribution came from one of Germany's grand old men, Professor Salin, who stressed the need for a management and sociological revolution, without which the technological revolution would be stillborn, and contrasted the American "job" with its built-in flexibility, with the German "Beruf" that concentrated on pension rights This came at the end of the last day, and was a fitting close to a conference which on the very first day had been aroused by Professor André Philip from France with an impassioned plea to examine "le sens même de notre civilization" His peroration included the memorable statement. "mais on ne peut démocratiser les technocrates si l'on n'a pas d'abord technicisé les démocrates"

What was said at this very impressive conference was, however, less important than who had organized it and who took part in it That a trade union had taken the initiative in this field and was co-operating with employers and the government was immensely encouraging, and it was unfortunate that the British trade union movement was not represented The German I G Metall is showing in a very practical way how co-operation on both the national and international planes can be to the benefit of all The excellence of the contributions of its members illustrated the strength of the union's research effort in this field, and showed that it is taking a responsible attitude towards the problems that are arising for employers and employees, and for society, through the progress of technology

DNA Restriction Enzyme from *E. coli*

by
MATTHEW MESELSON
ROBERT YUAN*
The Biological Laboratories,
Harvard University,
Cambridge, Massachusetts

An endonuclease which degrades foreign DNA has been isolated. The enzyme requires S-adenosylmethionine, ATP and Mg^{++}

MANY strains of *E. coli* can recognize and degrade DNA from foreign *E. coli* strains. Whether a foreign DNA molecule will be rejected can depend on non-heritable characteristics imparted to it by the cell from which it is obtained. Such characteristics are called host-controlled modifications[1-3]. For example, the ability of λ and several other bacteriophages to multiply on *E. coli* strain K depends on the bacterial host in which the phages were last grown. Phages grown in bacteria possessing the modification allele m_K multiply well, but phages grown in bacteria lacking m_K do not. Instead, their DNA is quickly degraded on entering cells of strain K. The ability of strain K to reject or "restrict" DNA from cells lacking m_K is itself under genetic control, the responsible allele being designated r_K (refs. 4 and 5).

More generally, cells with the restriction allele r_i can degrade DNA from cells lacking the corresponding modification allele m_i. Several different modification and restriction alleles are known[6,7]. As well as certain phage DNAs, bacterial DNA transferred between cells by conjugation or transduction is subject to host-controlled modification and restriction, suggesting that these phenomena play a part in regulating the flow of genetic information between bacteria.

There is evidence that the modification character of a DNA molecule is determined by its pattern of methylation[8,9]. The simplest hypothesis for the biochemical basis of restriction is that each restriction allele directs the formation of a nuclease specific for DNA lacking the corresponding modification character. We have detected, isolated and characterized such an enzyme; it is an endonuclease present in strain K that is specifically active against λ DNA from strains lacking m_K.

Restriction by bacterial extracts. Restriction by extracts of r_K bacteria was discovered as an ATP-dependent nucleolytic activity specific for DNA from λ grown on a m_K^- host. Fig. 1 shows the sedimentation profiles of ^3H λ K DNA and ^{32}P λ C DNA incubated without extract (*a*), with extract of the r_K strain *E. coli* 1100 (*b*), and with extract of its r_K^- derivative, strain 1100.293 (*c*). The sedimentation of λ K DNA is seen not to be affected by incubation with either extract. In contrast, the sedimentation rate of λ C DNA is specifically decreased by incubation with the r_K extract. We conclude that the activity is specific for unmodified DNA and occurs only in the restricting strain.

Purification of the enzyme. Purification of the restriction activity was at first frustrated by its apparent loss on dialysis of bacterial extracts. The difficulty was overcome when we found that both ATP and S-adenosylmethionine (SAM) are needed for restriction to occur. A role for SAM was suggested by the report that methionine, a biosynthetic precursor of SAM, is necessary for optimal restriction *in vivo* by methionineless bacteria (unpublished observations of W. B. Wood, cited in ref. 8).

Following the establishment of suitable assay conditions, the activity was purified as follows. *E. coli* 1100 was grown to 6×10^8 cells/ml. at 37° C in tryptone broth with 1 μg/ml. of thiamine hydrochloride. The cells were sedimented and stored at −20° C. 120 g of cells was suspended in 0.01 M *tris* *p*H 7.4, 2×10^{-4} M $MgCl_2$, 10^{-4} M EDTA, 2×10^{-3} M mercaptoethanol. All subsequent operations were conducted at approximately 4° C. The cells were extracted by blending with glass beads and the extract was centrifuged at low speed and then at 35,000 r.p.m. for two hours in the International *A*-170 rotor. The sediment possessed very little restriction activity and was discarded.

The high speed supernatant (300 ml.) was fractionally precipitated by adding dry $(NH_4)_2SO_4$. The material precipitating between 35 and 55 per cent saturation was dissolved in 100 ml. of 0.02 M potassium phosphate, *p*H 7.0, 10^{-4} M EDTA, 2×10^{-3} M mercaptoethanol (PEM), dialysed against the same buffer, and applied to a column of Whatman *DE* 52 DEAE cellulose 6 cm in diameter and 11 cm long that had been equilibrated with buffer. The column was washed with 600 ml. of buffer and eluted with a 1,000 ml. linear gradient of PEM running from 0.06 to 0.30 M potassium phosphate and collected in 50 ml. fractions. The restriction activity was found in two adjacent fractions with a mean phosphate concentration of 0.15 M.

The active DEAE fractions were combined, dialysed against PEM containing 0.02 M potassium phosphate, and applied to a 1 × 15 cm column of Whatman *P*11 phosphocellulose equilibrated with the same buffer. The column was washed with 40 ml. of buffer and eluted in 9 ml. fractions with a 300 ml. linear gradient running from 0.05 to 0.3 M phosphate. The restriction activity emerged in three adjacent fractions with a mean phosphate concentration of 0.16 M.

The pooled active phosphocellulose fractions were dialysed against 0.01 M potassium phosphate, *p*H 7.5, 10^{-4} M EDTA, and 5×10^{-4} M dithiothreitol, concentrated to 7.5 ml. by dialysis against dry 'Sephadex *G*-200', and dialysed again. The concentrate was applied in 2.5 ml. portions to 30 ml., 10–25 per cent glycerol gradients made up in the dithiothreitol buffer. After centrifugation at 25,000 r.p.m. for 20 h at 2° C in an International *SB*101 rotor, the activity was found in three adjacent 1 ml. fractions at a position corresponding to a sedimentation coefficient of approximately 12*S*. These were stored at −10° C and have been kept for nearly a year without noticeable inactivation. Table 1 summarizes the purification of the restriction enzyme.

Assays with a limiting amount of pure enzyme were conducted with and without the addition of extract of

---

* Fellow of the Damon Runyon Memorial Foundation.

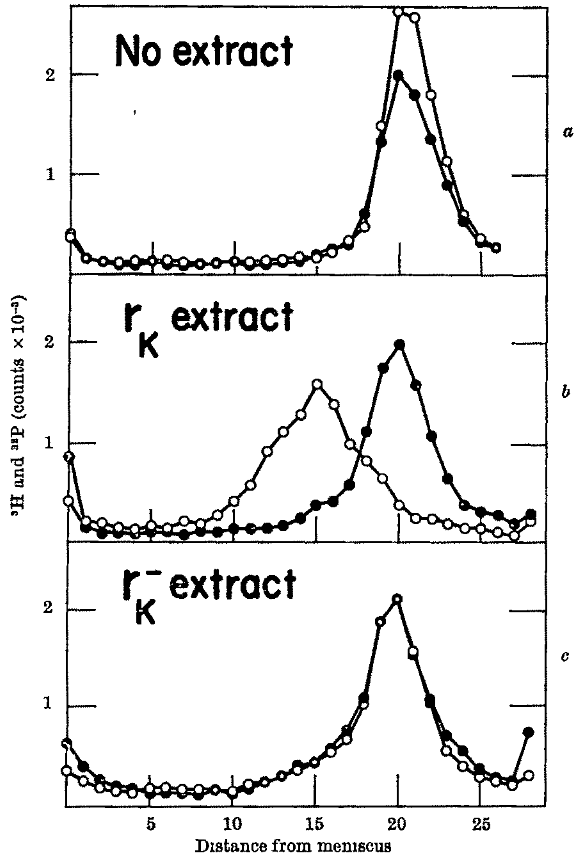

Fig 1 Sedimentation profiles of a mixture of ^{3}H λ K DNA and ^{32}P λ C DNA incubated for 10 min (*a*) without extract, (*b*) with extract of *E coli* strain 1100, or (*c*) with extract of strain 1100 293 Incubation mixtures (*b*) and (*c*) contained 1 mg/ml bacterial protein A 0 25 ml sample of each mixture was layered on a 3 5 ml 6–20 per cent sucrose gradient containing 0 01 M *tris* *p*H 8, 0 001 M EDTA, 0 04 per cent sodium dodecyl sulphate and centrifuged for 1 8 h at 55,000 r p m in an International *SB*405 rotor at 20° C Fractions were collected and counted by standard techniques ——●——, ^{3}H, ——○——, ^{32}P

the r_K^- strain 1100 293 The extract had no effect on the extent of the reaction, showing that the activity of r_K extract can be directly compared with that of the purified enzyme in computing the degree of purification achieved The failure of the r_K^- extract to inhibit the reaction also shows that the r_K^- phenotype results from a reduction in the amount or activity of the restriction enzyme rather than from the presence of an inhibitor

Requirements of the reaction Table 2 shows the effects of omitting various components of the reaction mixture. Restriction is measured as the inactivation of infectious λ C DNA Enzyme, ATP, Mg^{++} and SAM are all seen to be essential while gelatine, EDTA and mercaptoethanol are not Fig 2 shows the effect of lowering the concentration of ATP or SAM The requirement for SAM cannot be satisfied by l-methionine, 5′-thiomethyladenosine, S-adenosyl-*dl*-homocysteine or S-adenosylethionine ATP can be replaced by *d*ATP, although at limiting concentrations approximately twice as much must be used for the same degree of inactivation ATP cannot be replaced by GTP, ADP, AMP, adenosine, pyrophosphate or phosphate The optimal *p*H for the restriction reaction lies between 7 5 and 8 0

Table 1 PURIFICATION OF THE ENZYME

	Total protein (mg)	Activity
Low speed supernatant	8,000	~1
High speed supernatant	5,700	
$(NH_4)_2$ SO_4 precipitate	3,400	
DEAE eluate	260	
Phosphocellulose eluate	2	
Glycerol gradient fraction	⩽0·5	⪆5,000

Activity is expressed as the reciprocal of the mg/ml of protein required to break 90 per cent of λ C duplexes during a 10 min incubation under the assay conditions described in the text

Table 2 REQUIREMENTS FOR REACTION

	$\log_{10} \frac{\lambda K}{\lambda C}$
Complete system	2 0
–EDTA	2 0
–Gelatine	2 0
–Mercaptoethanol	2 0
–$MgCl_2$	0 0
–SAM	0 0
–ATP	0 0

The restriction enzyme is an endonuclease The action of the enzyme on ^{32}P λ C DNA liberates little or no non-sedimenting ^{32}P, showing that degradation is endo rather than exonucleolytic The action of the enzyme on λ twisted circles, DNA molecules without ends, confirms this Sedimentation analyses of a mixture of ^{3}H λ K and ^{32}P λ C twisted circles incubated with and without enzyme (Fig 3) prove that the enzyme readily degrades λ C twisted circles The enzyme, however, has no effect on λ K twisted circles, neither double nor single chain scissions are produced

The limit product is duplex DNA A mixture of ^{3}H λ K DNA and ^{32}P λ C DNA was incubated with enzyme, re-isolated by phenol extraction, dialysed against TNE, and again incubated with enzyme. Fig 4 shows that the second incubation caused little or no additional degradation A control incubation proved that intact ^{32}P λ C DNA added to the second incubation mixture was extensively degraded We conclude that the sedimentation profiles seen in the figure represent the limit product of the restriction enzyme under our reaction conditions The maxima of these profiles occur close to the position to which λ quarter molecules would sediment The sedimentation distribution of the limit product in 0 1 M salt was compared with that in 0 01 M salt No difference was observed Single DNA chains sediment about three times faster in the stronger salt solution, whereas duplexes sediment at the same rate in both solvents. We conclude that the limit product consists of duplexes containing little or no single stranded DNA

The limit product is without single-chain breaks. Clearly the enzyme is able to break the λ C duplex into a number of segments Conceivably, there are sites within these segments where the enzyme has broken only one of the two polynucleotide chains Such single-chain breaks would have little effect on the sedimentation behaviour of DNA duplexes They would, however, become apparent from a comparison of the molecular weight distribution of the reaction product before and after chain separation A mixture of ^{32}P λ C DNA and ^{3}H λ K DNA was extensively incubated with enzyme and then sedimented at 20° C on neutral and on alkali D_2O-H_2O gradients containing 0 9 M NaCl The alkali solvent dissociates duplexes into their component single chains Fig 5 shows the molecular weight distributions calculated from the sedimentation profiles in the two solvents Molecular weights

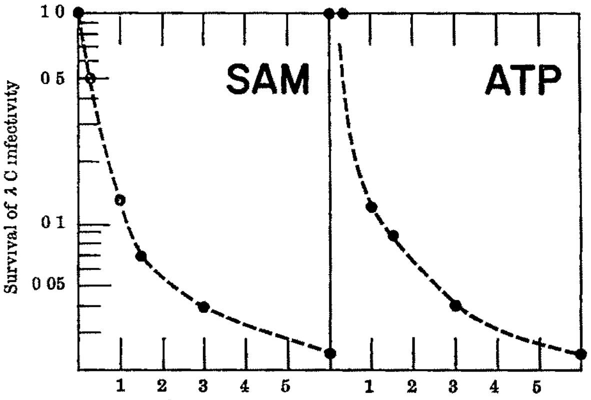

Fig 2 The dependence of restriction activity on SAM and ATP concentration.

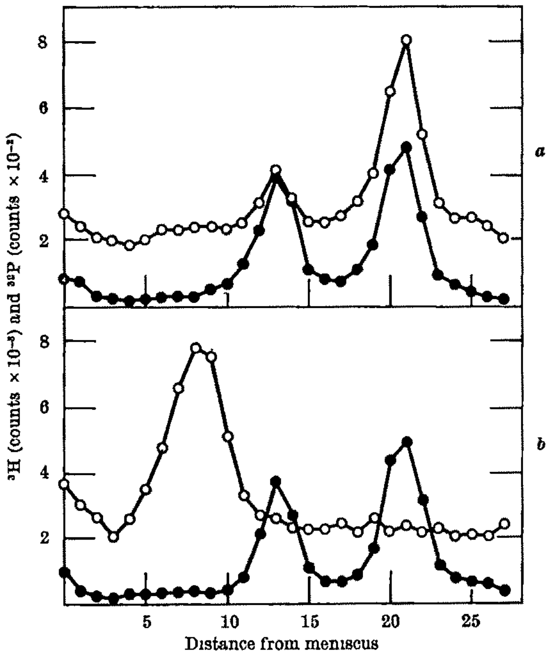

Fig 3 Sedimentation profiles showing the action of the restriction enzyme on twisted circular λ DNA molecules (*a*) A mixture of ^{3}H λ K and ^{32}P λ C DNA consisting mostly of twisted circular molecules but also containing the less rapidly sedimenting non-twisted circular form (*b*) The same mixture after 10 min of incubation with enzyme Samples were centrifuged for 1 h under the conditions given in the legend for Fig 1 ——○——, ^{3}H, ——●——, ^{32}P

are plotted as fractions of the weight of the intact duplex or single chain The near superposability of the two distributions shows that at least most of the limit product consists of duplexes without single chain breaks Only if located near the ends of the duplexes would any substantial number of single chain breaks have gone undetected by this test

Single chain scission precedes duplex cleavage. Prolonged action by the restriction enzyme breaks the DNA duplex into several pieces What is the timing with which individual chains of the duplex are broken ? Single and double chain scissions may be sensitively detected and distinguished by their effects on the twisted circular form of λ DNA (ref 18) Single chain scission converts twisted circles to the more slowly sedimenting non-twisted circular configuration. Double strand scission converts them to even more slowly sedimenting non-circular molecules Fig 6 shows the result of incubating a mixture of ^{32}P λ C twisted circles and ^{3}H λ K non-circular molecules with enzyme for 30, 60 and 120 s, after an initial lag, untwisted circles are produced before non-circular molecules appear Thus single strand scission precedes cleavage of the duplex The same conclusion has been reached by a comparison of neutral and alkali sedimentation analyses performed in parallel on samples taken at various times in the course of the reaction The occurrence of single chain scission early in the reaction, taken together with the paucity of single chain breaks in the limit product, indicate that the enzyme first breaks only one chain and then, a few seconds later, breaks the complementary chain at a point directly or nearly opposite Our results do not reveal whether a given enzyme molecule remains bound to catalyse the breaks on both chains or whether the two chains are attacked independently

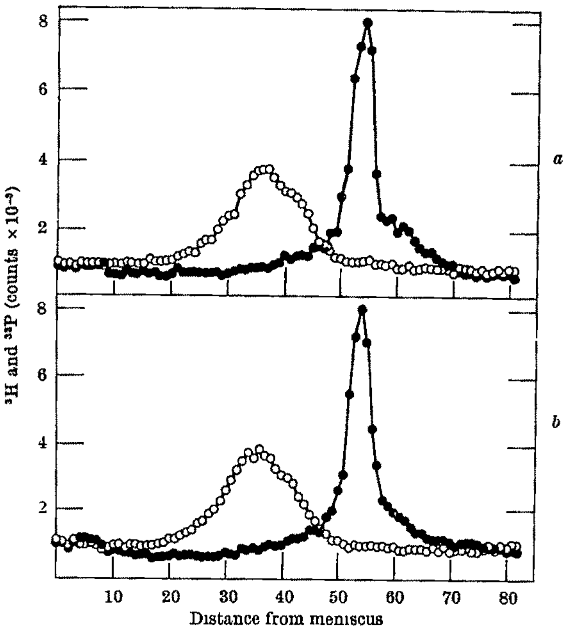

Fig 4 Sedimentation profiles of a mixture of ^{3}H λ K DNA and ^{32}P λ C DNA incubated with enzyme (*a*) once or (*b*) twice See text for details Samples of 0 4 ml were layered on 12 ml 15–28 per cent sucrose gradients containing 0 01 M *tris* *p*H 8 0, 0 001 M EDTA, 0 04 per cent sodium dodecyl sulphate and centrifuged for 17 h at 35,000 r p m in an International *SB*283 rotor at 2° C ——●——, ^{3}H, ——○——, ^{32}P

The infectivity assay employed to determine the requirements of the reaction is probably insensitive to single strand scissions, for λ DNA can be rather extensively nicked by pancreatic DNase without loss of infectivity[19]. We therefore reinvestigated the requirements for ATP, Mg^{++} and SAM by sedimentation analysis with ^{32}P λ C twisted circles as substrate We found that neither double nor single chain scission occurs if any one of the three components is omitted from the reaction mixture

Duplexes with only one modified chain are not attacked Separated polynucleotide chains of ^{3}H λ K DNA and ^{32}P λ C DNA were mixed in appropriate complementary combinations and annealed to obtain the two possible heteroduplexes (one chain modified, the other unmodified) and both homoduplexes Incubation with enzyme followed by sedimentation analyses on neutral and alkali gradients showed that unmodified homoduplexes are cleaved but that the enzyme does not act on modified homoduplexes

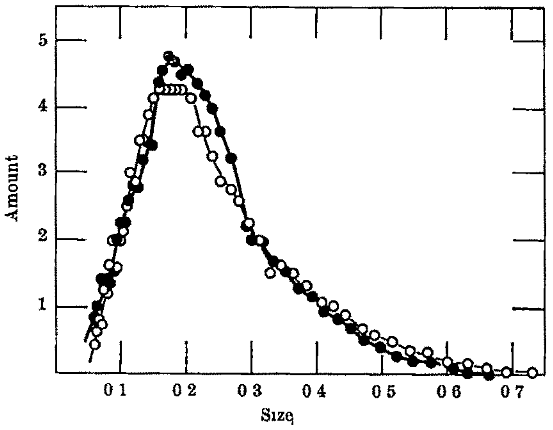

Fig 5 Molecular size distributions of the reaction product before (——○——) and after (——●——) strand separation Each point represents a fraction collected from the corresponding gradient A mixture of ^{3}H λ K DNA and ^{32}P λ C DNA was extensively incubated with enzyme and then analysed on 11 2 ml D_2O–H_2O gradients containing 0 9 M NaCl, 0 001 M EDTA and either 0 04 per cent sarcosyl *NL*97, 0 01 M *tris* *p*H 8 0 or 0 1 M NaOH The gradients were centrifuged in the *SB*283 rotor at 41,000 r p m for 3 3 h at 20° C, which moves the intact ^{3}H reference DNA about 85 per cent of the way down the gradient Sedimentation coefficients were computed for each fraction, taking into account the variation of acceleration, solution density, and viscosity along the gradient Molecular size relative to intact ^{3}H λ K duplexes or single chains taken as unity was obtained from the sedimentation coefficients[17] The ordinate for each point is the ^{32}P counting rate corrected for background and normalized to give the amount of DNA per unit molecular size No correction has been made for the effect of finite band width Parallel centrifugations of the DNA mixture incubated without enzyme showed the ^{32}P DNA to sediment in both neutral and alkali solution as a band with a half-width of three fractions at half its maximum concentration In the neutral gradient, the trailing edge was sharp while in alkali it displayed a tail indicating that approximately 1/4 of the polynucleotide chains were broken In neutral solution 10 per cent of the material sedimented slightly ahead of the leading edge while in alkali the leading edge was sharp

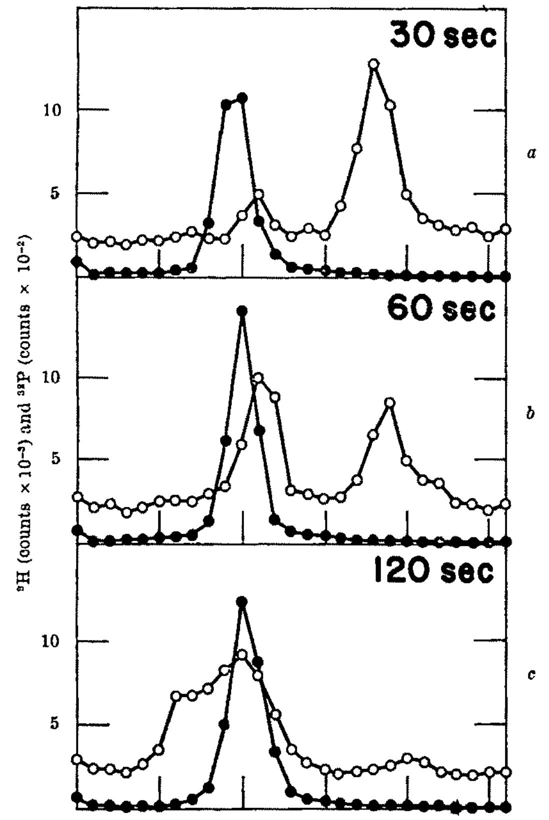

Fig 6 Sedimentation distributions of a mixture of ^{3}H λ K non-circular DNA and ^{32}P λ C twisted circular DNA after incubation with enzyme for (*a*) 30, (*b*) 60 and (*c*) 120 s The distributions of the untreated DNA mixture and of the mixture incubated with enzyme in a reaction mixture lacking ATP and SAM were essentially the same as that seen in (*a*) Samples were centrifuged for 1 1 h under the conditions given in the legend for Fig 1 ——●——, ^{3}H, ——○——, ^{32}P

or on either of the two heteroduplexes (Fig 7) Thus heteroduplexes are resistant even to single chain scissions

A restriction enzyme from P1 lysogenized cells We have partly purified a restriction activity from cells lysogenic for phage P1 which specifically breaks DNA duplexes of phage λ grown on strains not lysogenic for P1 Like the restriction enzyme from strain K, it requires Mg^{++}, ATP and SAM The product of its action also consists mainly or entirely of relatively large fragments of the λ duplex We propose that these enzymes be designated *E coli* endonuclease III K and III P, respectively

Discussion The degree of purification achieved and the diversity of the fractionation procedures employed make it most unlikely that the restriction activity we have isolated corresponds to more than a single molecular species, although it may well be a stable aggregate of two or more sub-units Indeed, the enzyme's high sedimentation coefficient, the complexity of its action and co-factor requirements suggest an aggregate

The ATP and SAM requirements of endonucleases III K and III P are unprecedented and we do not yet know whether either compound is consumed in the reaction or acts only catalytically, possibly as an allosteric effector The requirement for SAM is especially interesting because of the likelihood that modification corresponds to the specific methylation of DNA[8,9], presumably using SAM as a methyl donor It appears that the enzyme interacts directly with ATP, for it is rapidly inactivated when they are incubated together if SAM is absent

Takano, Watanabe and Fukasawa[20] have described a specific inactivation of unmodified infectious λ DNA by extracts of bacteria carrying certain restrictive episomes No ATP was added to their reaction mixtures In our experiments and in an earlier investigation (unpublished results of S Lederberg and M Meselson) using the λ infectivity assay system, neither K nor P restriction activity was detected in bacterial extracts without added ATP, the addition of SAM was unnecessary in our crude extracts It remains to be seen whether the enzymes associated with the restrictive episomes studied by Takano *et al* differ in their co-factor requirements from the K and P enzymes or whether there was adequate ATP (and SAM) naturally present in their extracts

The size distribution of the DNA fragments in the limit digest of the restriction enzyme poses several problems The very limited action of the enzyme *in vitro* contrasts sharply with the nearly complete and very rapid breakdown of unmodified DNA to acid soluble products seen *in vivo*[21,22] Perhaps the production of an end, or a certain type of end, quite generally exposes a DNA duplex to such breakdown within the cell, even though it is not clear that the known nucleases of *E coli* would be sufficient for this purpose[23] Although it seems very likely that the restriction enzyme attacks DNA at fixed sites, no clear indication of discrete species was seen in the sedimentation profiles of the limit product Depending on

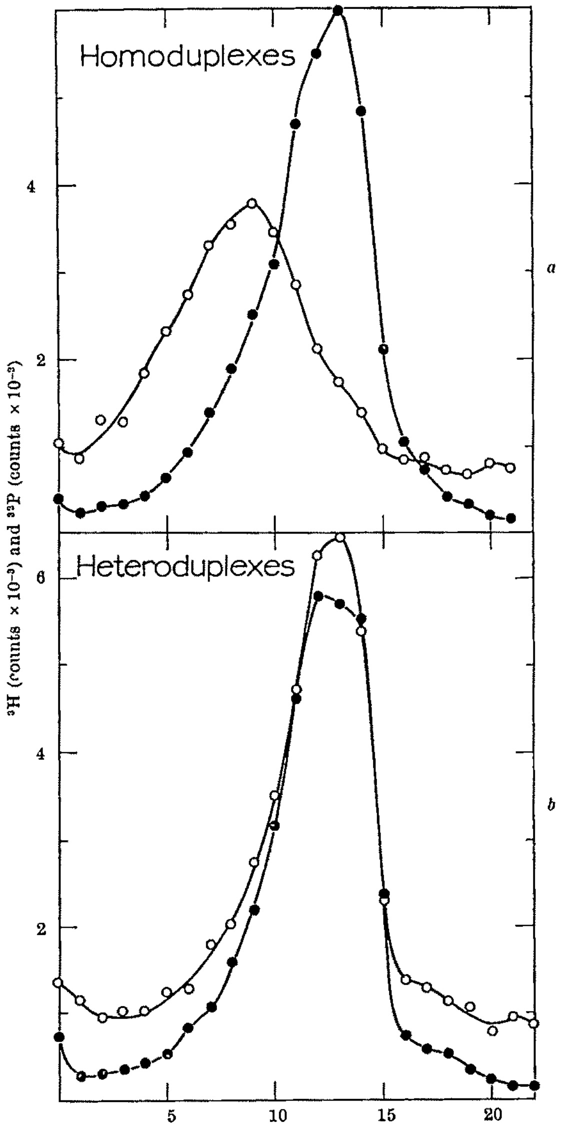

Fig 7 Alkali sedimentation profiles of (*a*) reconstituted ^{3}H λ K and ^{32}P λ C homoduplexes and (*b*) the two possible heteroduplexes after incubation with enzyme Samples of 0 2 ml were layered onto 3 5 ml 6–20 per cent sucrose gradients containing 0 005 M EDTA and 0 3 M NaOH and centrifuged 1 8 h at 55,000 r p m in the *SB*405 rotor at 20° C ——●——, ^{3}H, ——○——, ^{32}P

the distribution of susceptible sites, however, it is possible that different classes of fragments would not have been resolved under our conditions of analysis

The molecular size distribution of the limit product indicates that not all λ chromosomes are broken to the same degree For example, although there are segments of approximately 40 per cent length, they comprise much less than 40 per cent of the digest, as though an appreciable number of chromosomes did not react to give such segments If Fig 5 accurately portrays the molecular size distribution of the limit product, it may be that the initial population of DNA molecules was heterogeneous, some may already have been modified at one or a few sites. Alternatively, the restriction enzyme itself may occasionally render some sites resistant to cleavage Conceivably the restriction enzyme is also the modifying enzyme but with its modifying activity only weakly manifested in our assay system The presence of SAM in the incubation mixture, the close genetic linkage between r^- and m^- mutations, and the fact that a large proportion of r^- mutants are also m^- (refs 4, 5 and 24), are consistent with this interpretation, although other explanations can be given

It is definitely known that one, and somewhat less well established that both, of the two possible λ chromosomes with only one modified polynucleotide chain are able to infect and multiply normally in a restricting host[3]. Our finding that both types of λ heteroduplex are resistant to the restriction enzyme confirms these conclusions This shows that both polynucleotide chains of λ K DNA are modified at every site of potential attack The fact that heteroduplexes are resistant even to single chain scission indicates that the enzyme somehow takes account of the structure of both chains before cutting either The resistance of heteroduplexes may serve to protect newly replicated bacterial DNA from attack by the cells' own restriction enzyme, allowing time for modification of the newly synthesized chain Indeed, if restriction and modification are accomplished by the same enzyme, the choice between the two reactions may normally be governed by whether the substrate is an unmodified homoduplex or a heteroduplex, respectively The extreme destructive potential of the restriction system may have enforced selection for additional mechanisms to ensure that cellular DNA newly synthesized by replication or repair is modified before it can be restricted Various protective control mechanisms can obviously be devised involving the cofactor requirements for restriction and the sensitivity of the restriction enzyme to ATP when SAM is absent

If DNA synthesis in restricting bacteria could be continued beyond one generation after methylation has been blocked, the resulting unmodified homoduplexes should be vulnerable to cleavage and degradation by the cells' own restriction system Having made this prediction, we were struck by the report of Lark[25] that DNA synthesis in methionineless *E coli* 15T- halts one generation after methionine is replaced with ethionine or norleucine and that much of the cellular DNA may then become acid soluble Although the level of SAM may be very low during methionine deprivation, even one cleavage of the bacterial chromosome by restriction enzyme might stop replication and trigger extensive degradation According to this picture, DNA synthesis should continue beyond one generation and without degradation if Lark's experiments were repeated with a strain deficient in restriction

Finally, endonucleases III K and III P may provide a model for other systems that cleave duplexes or cut single chains at specific locations, not only in connexion with restriction phenomena, but possibly also in replication, recombination or transcription

Materials and Methods *Bacteria and bacteriophages* Strain C600 (ref 10), its derivative CR34 *thy* (ref 11) and the DNA endonuclease I deficient strain 1100 (ref 12) have the restriction and modification properties $r_K m_K$ Strain 1100 293 is an $r_{K_1}^- m_K$ mutant of strain 1100 Strains C600 4 and C600 5 are $r_K^- m_K^-$ Bacteriophage λ is the wild type of Kaiser[14] and λ*c* is a clear plaque forming mutant Phages grown on m_K^- strains are designated λ C, following the custom based on the fact that *E coli* strain C is m_K^- Taking the plating efficiency on strain C600 4 as unity, that on all other sensitive r_K^- strains employed was 1 0 and on r_K^- strains was 1 0 for λ K and 10^{-4} for λ C

DNA preparations Stocks of λ K and λ*c* C were made on strains C600 and C600 4, respectively, by the agar layer method Stocks of ^{3}H-thymidine λ K and ^{32}P λ C were produced by ultraviolet light induction of CR34 (λ) and C600 4 (λ) in radioactive media Phages were purified by two cycles of differential centrifugation followed by equilibrium sedimentation in CsCl solution DNA was extracted with water-saturated phenol, extensively dialysed against 0 01 M *tris*, 0 01 M NaCl 2×10^{-4} M EDTA, *p*H 7 4 (TNE) and stored at 0° C Before use in assays, DNA solutions were kept at 55° C for 5 min in order to disassociate end-to-end aggregates Twisted circular λ DNA was prepared by infection of *E coli* C600 4 (λ) or C600 (λ) with 10 ^{32}P λ C or ^{3}H λ K per cell, respectively After incubation for 30 min at 37° C in tryptone broth, the infected cells were sedimented, washed with 0 03 M *tris* *p*H 8 0, 0 01 M NaCl, and resuspended in the same medium at 5×10^8 cells/ml The suspension was made 0 02 per cent in lysozyme, incubated for 1 min at 37° C, made 0 01 M in EDTA, incubated for an additional minute, and lysed by the addition of 10 mg/ml sodium dodecyl sulphate The lysate was sheared by vigorous passage through a No 26 hypodermic needle, extracted with water-saturated phenol, dialysed against TNE, and sedimented through a neutral sucrose gradient containing 10^{-3} M EDTA After shear treatment, host cell DNA sediments much more slowly than λ twisted circles, which are relatively insensitive to shearing The fraction of the gradient containing twisted circles was dialysed against TNE and stored at 0° C

Polynucleotide chain separation and annealing Separated polynucleotide chains were prepared according to Hradecna and Szybalski[15], using poly UG rather than poly IG Broken chains and poly UG were removed by sedimentation through an alkali D_2O–H_2O gradient Complementary mixtures containing approximately 10 μg/ml of purified single chains were annealed by overnight dialysis at 37° C against 0 001 M EDTA, 0 1 M NaCl, NaOH *p*H 10 5 followed by dialysis against TNE (private communication from W Doerfler and D Hogness) More than 80 per cent of the annealed material sedimented at the same rate as native DNA duplexes in neutral 0 01 M salt Sedimentation analysis in alkali showed that most of the annealed duplexes were free of single chain breaks

Enzyme assays Restriction activity was assayed in a mixture containing, per ml 50 μmoles *tris*, 5 μmoles $MgCl_2$, 0 2 μmoles EDTA, 5 μmoles mercaptoethanol, 100 μg gelatine, 0 2 μmoles ATP, 0 02 μmoles S-adenosylmethionine (SAM), approximately 10^{10} phage units of ^{32}P λ C DNA and ^{3}H λ K DNA, and the enzyme sample to be assayed SAM was purified from the commercial product by elution from 'Biorex 70' with acetic acid The *p*H of the reaction mixture was 7 7 at 20° C After incubation for the desired time at 37° C, 1/10 volume of 0 4 M EDTA *p*H 9 5 was added and the mixture was subjected to sedimentation analysis

In some assays, radioactive DNA was replaced with approximately 10^9 phage units of a mixture of λ*c* C DNA and λ K DNA After incubation, the reaction mixture was diluted 1 100 in TNE and assayed for infectivity Restriction was measured as a decrease in the ratio of clear plaques to turbid plaques, relative to the ratio for the untreated DNA mixture λ K DNA is not inactivated by the purified enzyme The infectivity assay was that of Kaiser and Hogness[16] except for the following strain C600 5 was used as recipient and C600 4 (λi^{434}) as indicator Recipient cells were prepared by 4 5 h growth at 37° C from a 1 3 dilution of an overnight culture Glycerol rather than glucose was used as carbon source The bacteria were sedimented, resuspended at 2×10^9/ml in 0 01 M $MgSO_4$ infected with 5 λi^{434} phages per cell, incubated for 7 min at 37° C, diluted 1 1 with iced 0 01 M *tris* *p*H 8 0, 0 01 M $CaCl_2$, 0 01 M $MgSO_4$, sedimented, and resuspended at 2×10^9/ml in the same solution The cells were kept at 0° C for 2–12 h before use The efficiency of the assay was approximately 0 01 plaques per phage unit of λ DNA Infectivity assays were useful for detecting restriction activity only after the phosphocellulose chromatography step in the purification of the enzyme Less purified enzyme preparations caused severe non-specific inactivation of infectivity

Strengthening of Silicate Glasses by Ion Exchange

by
D K HALE
Division of Inorganic and Metallic Structure,
National Physical Laboratory,
Teddington, Middlesex

Surface defects are almost always present in glass, reducing its strength. One way of overcoming this is to replace cations in the surface layer with larger cations from a molten salt

A GENERAL characteristic of brittle solids is that surface cracks or other defects can lead to local stress concentrations and a fracture strength which is very much less than the intrinsic strength of the material Glass is a typical example—"ordinary glass" usually has a strength of the order of a few thousand lb /in ^{2} but, if special care is taken to avoid surface defects in manufacture, strengths of more than 300,000 lb /in ^{2} can be obtained even in rods[1], and very much higher strengths are observed with fibres

The presence of surface defects in glass must usually be accepted as inevitable Most of the successful methods for strengthening glass have involved the introduction of compressive stress in the surface layers to overcome the strength-impairing effects of surface cracks or other defects In thermal tempering, for example, compressive stress is introduced by rapid cooling Strength increases of up to 30,000 lb /in ^{2} can be achieved in this way

A most effective method of strengthening glass, known as chemical strengthening, has recently been developed In this method, small cations initially present in the glass are replaced by larger cations from a molten salt[2–6] The exchange process is confined to a thin layer next to the glass surface The strengthening treatment is carried out at a temperature below the annealing range so that the stresses introduced are not removed by relaxation On cooling, a permanently stressed layer with a thickness of from 50μ to a few tenths of a millimetre is obtained Strengths of more than 100,000 lb /in ^{2} can be attained which are not impaired by mild abrasion This method (or a suitable modification) should be applicable to other brittle solids and has indeed been applied recently to glass ceramics , the strength of nepheline glass ceramics was increased from less than 8,000 lb /in ^{2} to more than 200,000 lb /in ^{2} (ref 7)

Although the kinetics of ion-replacement processes in glasses have been investigated in some detail[6,8,9], there seems to be no published work on the nature of the ion-exchange equilibrium between the bulk glass and the molten salt The factors which determine the distribution of the exchanging ions between the glass and the molten salt would be expected to decide the ease with which one ion can be replaced by another and the compressive stress which can be achieved

In considering the ion-exchange equilibrium between a silicate glass and a molten salt, it will be assumed that the basic structure of the glass consists of an irregular three-dimensional network built up from silicon–oxygen tetrahedra in which each silicon ion is surrounded by four oxygen ions The tetrahedra are linked together at the corners by sharing a common oxygen ion In places, the silicon ions are linked to "non-bridging" oxygen ions instead of through —O— linkages to other silicon ions, thus providing sites for cations such as Na^+, K^+, Ca^{++} The alkali metal ions can diffuse through the structure and small ions in the glass (Na^+, Li^+, for instance) can be replaced by larger ions (such as K^+) from the molten salt In the strengthening process this ion replacement leads to an increase in volume This takes place against the elastic forces in the silicate network and the mechanical restraint imposed by the glass substrate which, if relatively thick, can be assumed to be rigid

If we consider the replacement of one univalent cation by another the exchange process can be represented by the equation

$$\bar{A}+B \rightleftarrows \bar{B}+A \tag{1}$$

where A and B represent the two cations in the molten salt and $\bar{A}$ and $\bar{B}$ represent the same cations in the glass

The electrochemical potential $\bar{\eta}_i$ of a species i in the glass will be given by

$$\bar{\eta}_i=\bar{\mu}_i+z_iF\bar{\varphi} \tag{2}$$

where $\bar{\mu}_i$, $\bar{\varphi}$, z_i and F are the chemical potential, the electric potential, the electrochemical valence and the Faraday constant, respectively

Assuming an isothermal system and splitting $\bar{\mu}_i$ into two parts—$\bar{\mu}_i'$ representing the composition-dependent part of the chemical potential and $\bar{\mu}_i''$ the contribution due to the change in mechanical strain energy when one ion is replaced by another—we have

$$\bar{\eta}_i=\bar{\mu}_i'+\bar{\mu}_i''+z_iF\bar{\varphi} \tag{3}$$

For the molten salt

$$\eta_i=\mu_i+z_iF\varphi \tag{4}$$

At equilibrium the electrochemical potentials $\bar{\eta}_i$ and η_i will be the same, so that because A and B are univalent cations ($z_i=1$) we have

$$F(\bar{\varphi}-\varphi)=\mu_A-\bar{\mu}_A'-\bar{\mu}_A'' \tag{5}$$

and

$$F(\varphi-\varphi)=\mu_B-\bar{\mu}_B'-\bar{\mu}_B'' \tag{6}$$

Introducing activities we obtain the relationship

$$RT\ln\left(\frac{\bar{a}_Aa_B}{\bar{a}_Ba_A}\right)=(\bar{\mu}_B''-\bar{\mu}_A'') \tag{7}$$

where a_A and a_B are the activities of A and B in the molten salt, and $\bar{a}_A$ and $\bar{a}_B$ are the corresponding activities in the glass

If we now define a selectivity coefficient K_B^A by the relation

$$K_B^A=\frac{\bar{c}_Ac_B}{\bar{c}_Bc_A} \tag{8}$$

where c_A and c_B are the concentrations of the ions in the molten salt and $\bar{c}_A$ and $\bar{c}_B$ are the corresponding concentrations in the glass, we have

$$\ln K_B^A=\ln\left(\frac{\bar{\gamma}_B}{\bar{\gamma}_A}\right)+\ln\left(\frac{\gamma_A}{\gamma_B}\right)+\left(\frac{W_m}{RT}\right) \tag{9}$$

where $W_m=(\bar{\mu}_B''-\bar{\mu}_A'')$ and γ_A, γ_B, $\bar{\gamma}_A$ and $\bar{\gamma}_B$ are the activity coefficients of the ions A and B in the molten salt and the glass, respectively

In this relationship the first two terms on the right-hand side represent the effect of chemical factors on the selectivity coefficient The last term represents the effect of the mechanical forces W_m is the mechanical work involved in the replacement of 1 mole of cation A by an equivalent amount of cation B, and includes any work which may be done against external forces

Some indication of the effect of the first two terms on the selectivity coefficient can be obtained from existing physico-chemical data The effect of the third term is considered below

The value of W_m in the absence of external restraints may be estimated by assuming that the glass is an elastic continuum and applying the "misfitting sphere" theory This approach has very obvious weaknesses but, as Eshelby[10] has pointed out, the limitations are perhaps more immediately obvious than the shortcomings of other approximate treatments. This type of approach, using the methods of classical elasticity, has been used with various modifications and with varying degrees of success in theories of the formation of lattice defects[10,11], precipitation hardening[12] and the thermodynamic properties of solid solutions of metals[13]. The following discussion of strain energy effects on ion exchange in glasses is based on the treatment of misfit energy in metallic solid solutions given by Eshelby[10] and Christian[13].

We assume that the glass is initially stress free and first consider the replacement of an ion A (radius r_A° and volume v_A°) by the larger ion B (radius $r_B^\circ = (1+\varepsilon)r_A^\circ$ and volume v_B°) in an infinite elastic continuum. We remove the ion A from the glass and expand the cavity to accommodate the ion B which can be assumed to be either a rigid or an elastic sphere. In the latter case, at equilibrium, the volume of the B ion will become v_B and its radius $r_B = (1+C\varepsilon)r_A^\circ$.

$$C = \frac{3K_B}{(3K_B + 4G_M)} \qquad (10)$$

where K_B is the effective bulk modulus of ion B and G_M is the shear modulus of the matrix. ($C=1$ and $v_B = v_B^\circ$ if the B ion is incompressible.)

For an infinite continuum there is no dilatation of the matrix (in other words, the density is constant). If we consider a closed surface in the continuum which encloses the A ion, it can then be shown that the volume enclosed by the surface will increase by Δv^∞ when the A ion is replaced by the B ion, and that

$$\Delta v^\infty = C\,\Delta v_{AB} \qquad (11)$$

where

$$\Delta v_{AB} = v_B^\circ - v_A^\circ = 4\pi\varepsilon(r_A^\circ)^3 \qquad (12)$$

When the exchange process takes place in a finite body of glass, the boundary conditions used in the previous solution are no longer applicable, but a solution can be obtained by superimposing a set of "image" displacements caused by surface tractions. For the case of a sphere (with the A ion at the centre) there is a uniform dilatation of the matrix and the increase in volume caused by image forces is

$$\Delta v^i = (4G_M/3K_M)\,\Delta v^\infty \qquad (13)$$

where K_M is the bulk modulus of the matrix.

The total increase in volume of the system is

$$\Delta v = \Delta v^\infty + \Delta v^i = \left(\frac{C}{C'}\right)\Delta v_{AB} \qquad (14)$$

where

$$C' = \frac{3K_M}{(3K_M + 4G_M)} \qquad (15)$$

This result for the change in volume has been shown by Eshelby[10] to be valid for any external surface. If the effective bulk modulus of the ion B is assumed to be equal to that of the matrix, then it follows from equations (10) and (15) that $C = C'$ and

$$\Delta v = \Delta v_{AB} = v_B^\circ - v_A^\circ \qquad (16)$$

The strain energy of the whole system is

$$W_s = 6G_M C\varepsilon^2 v_B \qquad (17)$$

and because $\varepsilon = \dfrac{\Delta v_{AB}}{3v_B}$

$$W_s = 2G_M\,C\,\frac{(\Delta v_{AB})^2}{3v_B} \qquad (18)$$

Equations similar to equation (17) have been derived by Frenkel[11] (for a rigid sphere) and by Friedel[14].

In a finite body of glass there is a dilatation of the matrix when ion A is replaced by the larger ion B, so the successive introduction of B ions becomes progressively easier. This effect can be expressed in terms of an interaction energy which will reduce the value of W_s as the fraction of B ions increases. In glasses, where the exchangeable ions occupy a relatively small proportion of the total volume, the effect is, however, expected to be small.

From the volume increase given by equation (16) we can estimate the compressive stress p which will be developed in a surface layer when A ions are replaced by B ions. If the underlying glass is assumed to be rigid so that expansion can take place in one direction only, it can readily be shown that the compressive stress is given by the approximate relationship

$$p = \left(\frac{\Delta v_0}{3v_0}\right)\left(\frac{E}{1-\rho}\right) \qquad (19)$$

where Δv_0 is the increase in volume of a volume v_0 of glass containing 1 mole of ion A, when the A ions are replaced by B ions. E is Young's modulus and ρ is Poisson's ratio.

The effect of external mechanical restraint on the ion-exchange equilibrium has not so far been considered. The work W_e done against the external forces when the glass is free to expand in one direction only can be estimated using equation (19), and is given by

$$W_e = \left(\frac{2}{3}\right)p\,\Delta v_0 \qquad (20)$$

If we know the appropriate values of v_A° and v_B°, we can now obtain W_s from equations (17) or (18). W_e can be obtained from equation (20) and the value of the selectivity coefficient K_B^A can be estimated from equation (9) if we assume that the effect of the first two terms on the right-hand side is relatively unimportant. We can also obtain the increase in volume from equation (16) and the compressive stress developed in a surface layer from equation (19).

The difficulty in the application of these relationships lies in the selection of appropriate values for v_A° and v_B°. It is clearly unlikely that the size of the cavity is determined by ionic radii equal to those in crystals. Indeed, if W_s is calculated for the replacement of Na ions by K ions assuming that $r_{\mathrm{Na}} = 0.95$ Å, $r_{\mathrm{K}} = 1.33$ Å, $E = 7\times10^5$ kg cm^{-2} and $\sigma = 0.25$, then $W_s = 13.9$ Cals mole^{-1} which would mean that the replacement of Na ions by K ions would be practically impossible because $K_{\mathrm{K}}^{\mathrm{Na}}$ would be of the order of 7×10^4 at 400° C. It is most likely that the size of the cavity will be determined by steric factors involved in the arrangement of the silicon–oxygen tetrahedra around the alkali metal ions and that the cavity may be similar to those in cristobalite. We can, however, assume an arbitrary effective radius for the cavity which gives the required volume expansion and then use this value to estimate the selectivity coefficient and the compressive stress which would be attained in the strengthening process.

To illustrate the application of these relationships to an actual system, we will consider the replacement of Na ions by K ions in a glass initially containing 1 mole of Na ions in 60 cm^3 of glass. If we assume that the Na ion is situated in a cavity with an effective radius of 1.15 Å, that the glass is initially stress-free and that the Na ion is replaced by a K ion with a radius of 1.33 Å, then the change in volume of the system will be 2.1 cm^3 mole^{-1}. This is in agreement with values of 1.25 to 3.5 cm^3 mole^{-1} calculated from the approximate data given by Burggraaf[15] for the increase in thickness of a surface layer after ion exchange. (It may be noted that these values are considerably less than the value of approximately 7 cm^3 mole^{-1} which would be expected from the difference in the densities of sodium and potassium glasses of similar composition prepared by melting.) From the volume increase and using equation (19) we can estimate the compressive stress which would be developed in a surface layer. Assuming $E = 7\times10^5$ kg cm^{-2}, $\sigma = 0.25$ and $v = 60$ cm^3, we obtain a value of 11,000 kg cm^{-2}, in reasonably good agreement with the value of 8,400 kg cm^{-2}

obtained experimentally by Burggraaf[16] with a glass containing 20·15 per cent by weight of Na_2O. From equation (17) a value of 2·65 Cal mole^{-1} is obtained for W_s. This corresponds to a value of 7·3 for K_K^{Na} at 400° C if we assume that $\bar{\gamma}_{Na}/\bar{\gamma}_K = \gamma_{Na}/\gamma_K$. Avalue of 0·36 Cal mole^{-1} is obtained for W_e from equation (20) assuming that $p = 11{,}000$ kg cm^{-2} and $\Delta v = 2{\cdot}1$ cm^3 mole^{-1}. The value of K_K^{Na} would therefore be expected to increase from 7·3 towards 9·5 as compressive stress is developed in a surface layer. A value of approximately 9 for K_K^{Na} would mean that there would be some difficulty in replacing Na ions by K ions but that 90 per cent replacement could be achieved if the ion-fraction of Na in the molten K salt is not allowed to exceed 1·2 per cent. Although the effect of the bi-axial compressive stress on the selectivity coefficient is relatively small, it would be expected that during the initial stages of the exchange process there would be a tendency for the K ions to form linear arrays perpendicular to the surface. (In a system with uniaxial compression a layered type of structure might be expected.)

In discussing the effect of the strain energy term on the ion-exchange equilibrium it has been implicitly assumed that the ions are situated in randomly distributed sites. There is, however, evidence that, in the caesium and rubidium silicate glasses, the non-bridging oxygens are closely associated in pairs and that with the potassium, sodium and lithium glasses, larger clusters may be formed[17,18]. This non-uniform distribution of exchangeable ions may be expected to have some effect on the validity of the model used in estimating the value of the strain energy term, but it would be expected that the model would still provide an approximate indication of the magnitude of the strain energy effects. It has also been assumed that the effect of the first two terms in equation (9) is relatively small. On the basis of Eisenman's theory of glass electrode behaviour[19] it would appear that the importance of these two terms relative to the strain energy term will depend primarily on the difference between the effective anionic radii in the glass and in the molten salt.

The model used in this discussion of ion replacement processes in silicate glasses is clearly an approximation, but the relationships derived show how the compressive stress achieved in the strengthening process will depend on the nature of the exchanging ions, on the concentration of ions introduced into the glass, on the elastic properties of the glass and on the conditions used in the replacement process. To achieve a high compressive stress in the strengthening process a high proportion of the replaceable alkali ions initially present in the surface layer have to be replaced by larger ions. If the ions differ considerably in size, the effect of the strain energy term on the selectivity coefficient will clearly become of considerable importance and may lead to a high value for K_B^A. The extent of exchange which can then be attained will be very sensitive to the presence of low concentrations of ion A in the molten salt and it will be difficult to achieve the required degree of replacement under practical conditions. The effect of the strain energy term may, however, be offset by the effect of the first two terms in the RHS of equation (9). By a suitable selection of the molten salt system or by a suitable modification of the glass (the use of an aluminosilicate glass, for example) it may be possible to increase the value of $\bar{\gamma}_B \gamma_A / \bar{\gamma}_A \gamma_B$ and thus reduce the effect of the strain energy term on the selectivity coefficient

Addendum

Further support for the theory of ion-exchange strengthening developed here is provided by the work of Rothermel[20]. In a study of the effect of stress on the durability of ion-exchanged surfaces, two aluminosilicate glasses were heated below their strain points in KNO_3 baths containing up to 10 per cent $NaNO_3$ as a contaminant. Glass F initially contained (on a mole per cent basis) 12·3 per cent Na_2O and 2·8 per cent K_2O; glass G contained 12·4 per cent Na_2O and 2·6 per cent K_2O. Treatment for 6 h at 525° C in 100 per cent KNO_3 led to approximately 90 per cent exchange at the surface and a modulus of rupture value of 70,000 lb./in.^{2} (90,000 lb./in.^{2} for unabraded samples). With abraded samples treated in KNO_3 containing 10 per cent $NaNO_3$, the exchange at the surface was approximately 55 per cent and the modulus of rupture was 40,000 lb./in.^{2}.

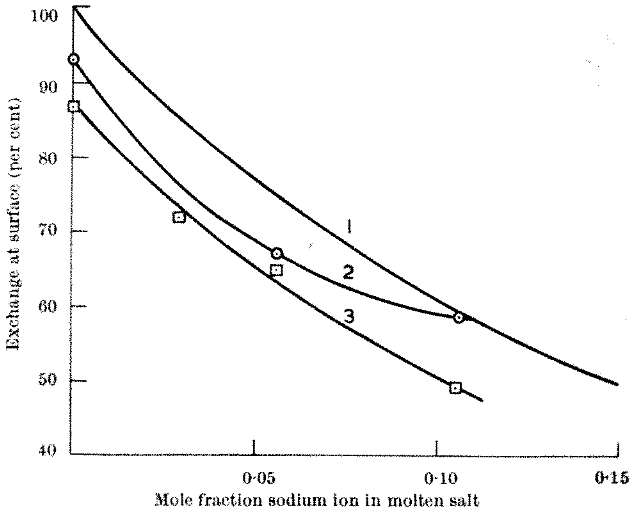

Fig. 1. Effect of sodium ion concentration in molten salt on ion exchange at a glass surface. 1, Theoretical relationship; 2, experimental (Rothermel, glass G); 3, experimental (Rothermel, glass F).

These experimental values may be compared with the theoretical values for a glass containing 11·6 per cent Al_2O_3, 12·4 per cent Na_2O and 76·0 per cent SiO_2. If we assume a density of 2·40 g cm^{-3}, the volume of glass containing 1 mole of Na^+ will be 109 cm^3. If we now take, as before, a value of 2·1 cm^3 mole^{-1} for the change in volume of the system on replacing Na by K ions and assume that $E = 7 \times 10^5$ kg cm^{-2} and $\sigma = 0{\cdot}25$, we obtain values of 76,500 lb./in.^{2} and 46,750 lb./in.^{2} for the compressive stresses introduced by 90 per cent and 55 per cent exchange, respectively. These theoretical values are rather higher than the modulus of rupture values for abraded samples, but the agreement is not unreasonable if it is assumed that the strength of untreated abraded samples is low. Because the value of W_s depends solely on the elastic constants and the volume change, it will have, as before, a value of 2·65 Cal mole^{-1}. This will correspond to a value of 5·3 for K_K^{Na} at 525° C if we assume that $\bar{\gamma}_{Na}/\bar{\gamma}_K = \gamma_{Na}/\gamma_K$. A value of 0·197 Cal mole^{-1} is obtained for W_e when the compressive stress is 5,990 kg cm^{-2}. This means that the theoretical value of K_K^{Na} will increase from 5·3 towards 6·0 as compressive stress develops in the surface. The theoretical relationship between the percentage exchange at the surface and the mole fraction of Na in the molten salt is shown in Fig. 1, which also includes Rothermel's results with the two aluminosilicate glasses. (It has been assumed that the mole fraction of Na ions in the molten salt in Rothermel's experiments can be calculated from the amount of added $NaNO_3$ and that the amount of sodium transferred from the glass to the molten salt is negligible.) It will be seen that the effect of added $NaNO_3$ on the extent of exchange at the surface is very similar to that which would be expected from the theory.

I thank Mr H. L. Cox for helpful discussions and comments.

Mechanism of Oxidation of Magnetite to γ-Fe_2O_3

X-ray diffraction and kinetic measurements show that the rate of oxidation of magnetite crystals smaller than about 0.2μ to γ-Fe_2O_3 is controlled by the diffusion of iron cations. A model of the mechanism is successful in describing the kinetics of the process.

THE oxidation of Fe_3O_4 to γ-Fe_2O_3 has been investigated many times since the establishment of the close relationship between the structures of the two oxides, and since Hägg[1] first discussed the mechanism of the reaction. Feitknecht and Lehmann[2] showed that this oxidation was a one phase topotactic reaction. (We have used here the nomenclature of Mackay[3].) The oxide ion lattice remains cubic close packed and oxygen layers are added as the iron cations migrate to the surface. The results of Egger and Feitknecht[4] indicate that particle size not only determines the rate of the reaction but also whether the α or the γ form of Fe_2O_3 is obtained. When pure magnetite is oxidized below 220° C, particles less than about 3000 Å in diameter always yield γ-Fe_2O_3 while larger particles are first oxidized to a composition intermediate between Fe_3O_4 and Fe_2O_3, and then undergo disproportionation into Fe_3O_4 and α-Fe_2O_3. The Fe_3O_4, which has reappeared, is oxidized directly to α-Fe_2O_3 in the last stages of the reaction. Below 220° C, γ-Fe_2O_3, although metastable at these temperatures, remains unchanged for indefinite periods, but above about 250° C the transformation to the thermodynamically stable α-form may be observed. This transformation, which is quite a different phenomenon from the formation of α-Fe_2O_3 during the oxidation of the larger particles, has been the object of a separate study[5]. Because the oxidation of Fe_3O_4 is important in many fields, such as mineralogy and corrosion, and because the mechanism of the oxidation to the γ form has the appearance of being a special type of topotactic reaction[6], a comprehensive investigation employing X-ray and kinetic techniques was undertaken. This report describes the salient features of the study and proposes a model for the reaction mechanism.

The magnetite sample was prepared by a method[1,7] which produces uniform, monocrystalline cubes (see Fig. 1). The Fe^{2+} content was 24·6 per cent of the total iron content, which is the highest obtainable for particles of this size when prepared by this method. Electron micrographs showed that during oxidation the cubes remained intact and monocrystalline, and that the surface area as measured by the BET method, 6·2 m^2g^{-1}, remained virtually unchanged throughout. This and all previous evidence indicates that this system belongs to the topotactic class of solid state reactions.

Apart from some intensity changes and small line shifts the X-ray diagrams taken at successive stages of the oxidation are identical with those of stoichiometric magnetite, Fe_3O_4, down to a composition of about 22 per cent Fe^{2+} (see Fig. 2). Below this composition reflexions of the primitive lattice of the $LiFe_5O_8$ structure appear, indicating that cation holes are being created on the "lithium" sites of the structure. Between 8·5 and 6·5 per cent Fe^{2+} the tetragonal reflexions of γ-Fe_2O_3 emerge. The structure of γ-Fe_2O_3 is related to the $LiFe_5O_8$ structure but with holes and cations ordered in the sequence Fe □ □ Fe □ □ Fe □ □ Fe □ □ Fe along a spiral of the "lithium" sites, which gives rise to the tetrahedral symmetry[8]. Calculations show that at 9·09 per cent Fe^{2+} the number of occupied and empty "lithium" sites are equal and if ordered the cubic symmetry of the $LiFe_5O_8$ structure would be retained, but below this composition any kind of ordered sequence along the "lithium" spiral will result in a loss of cubic symmetry. Fig. 3 shows the variation in the intensity of the (111) reflexion, measured at successive stages of oxidation from 24·6 per cent to zero per cent Fe^{2+}, and during reduction with hydrogen from 24·6 to 30 per cent Fe^{2+}. At about 8 per cent there is a break in the curve which we believe is associated with the emergence of the tetrahedral reflexions at or near the same composition.

The profile of the α(440) reflexion was measured at different stages of oxidation after quenching to room temperature. The Bragg angle was found to move con-

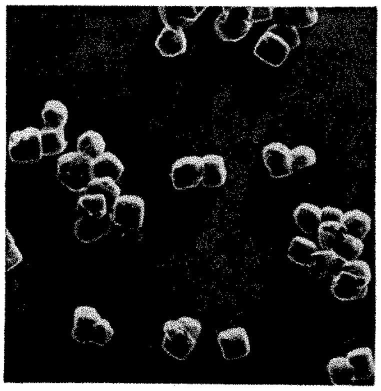

Fig. 1. Electron micrograph of a magnetite sample. The average length of the cube edge is 1940 ± 100 Å, which agrees closely with the value 1870 ± 30 Å calculated from BET surface area measurements.

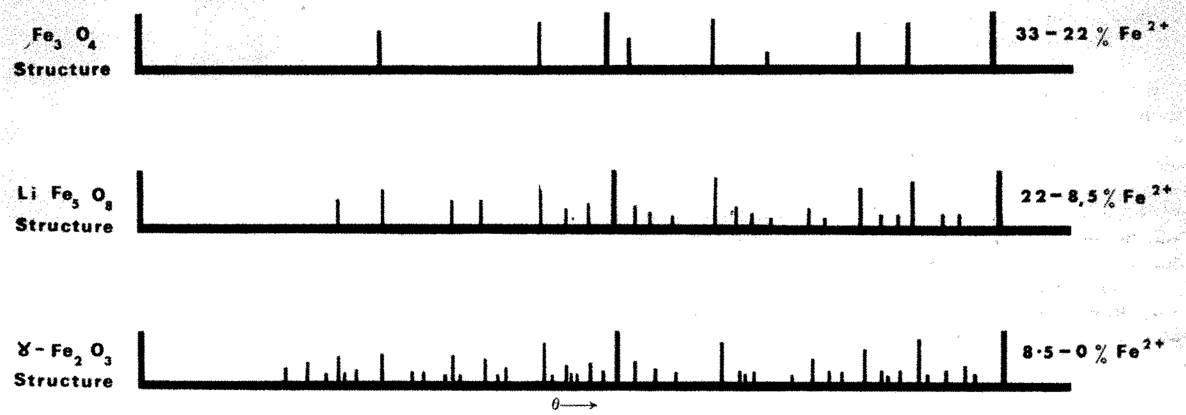

Fig. 2. Comparison of Guinier photographs taken at different compositions. New lines are always weak when they first emerge with decreasing Fe^{2+} content but increase in intensity to a maximum at the end of the composition range for that structure.

tinuously from 72·73° to 73·13°, the value for γ-Fe_2O_3, and the line profile at first gradually broadened asymmetrically to a maximum, and then slowly returned to its original width and shape towards the end of the reaction. If the reaction is interrupted the original width and shape (but not the Bragg angle) could be restored by annealing. The difference in asymmetric broadening between annealed and unannealed samples enabled the lattice strain to be calculated by the method of Kochendörfer[14] and was found to be a maximum at 16 per cent Fe^{2+}, but the change in line width and profile is much less than that expected from the concentration gradient normally associated with a diffusion mechanism. This point assumes considerable importance in the discussion of the mechanism.

For the kinetic investigations, 70–80 mg aliquots of magnetite were oxidized at 190° C to different compositions and annealed thoroughly. The kinetics of oxidation were measured on a Cahn electrobalance for all compositions at 190° C and the fractional uptake of oxygen plotted against $\sqrt{t}$ (Fig. 4) and against $t/t_{1/2}$, where $t_{1/2}$ is the time for half reaction (Fig. 5). Initially all the kinetic runs obey a parabolic law characteristic of diffusion when the semi-infinite solid conditions hold and when the boundary conditions of uniform initial concentration throughout the solid and constant surface concentration apply. The fraction F of the reaction over which the parabolic law is obeyed depends on the variation of D, the diffusion coefficient, but unless this changes discontinuously or extremely rapidly a well defined parabolic curve, usually up to at least $F = 0{\cdot}5$, is always found. For this reason, the experimental results of diffusion controlled reactions, measured under the boundary conditions given here (and in the absence of discontinuous changes of D), follow or almost follow the same curve up to $F = 0{\cdot}5$ when plotted on a reduced time scale, $t/t_{1/2}$. Reduced time plots are therefore of little value in distinguishing diffusion reactions in the region $F = 0$ to 0·5, but at higher F values they are much more sensitive to the type of diffusion mechanism prevailing.

The theoretical curve for diffusion into a cube under these boundary conditions and for a constant diffusion coefficient throughout was calculated from the analytical equation and is plotted as curve c alongside the experimental runs in Fig. 5. None of the runs followed this curve at all, but runs for an initial concentration of less than about 10 per cent Fe^{2+}, however, appeared somewhat similar. The symmetry of the crystal in this composition range is tetragonal and according to Neumann's principle diffusion is not necessarily isotropic but only limited by the restriction $D_x = D_y$ where D_x and D_y are the diffusion coefficients parallel to the a and b crystallographic axes, respectively. The possibilities for diffusion in a tetragonal crystal will fall into two categories.

(1) $D_x = D_y > D_z$ where D_z is the coefficient of diffusion along the c crystallographic axis. The two limits of this range are $D_z = 0$ and $D_z = D_x$. The former was computed and plotted as curve b in Fig. 5. The latter is the isotropic case and is therefore represented by curve c.

(2) $D_x = D_y < D_z$. The two limits here are $D_x = D_y = 0$ and $D_z = D_x$, the latter again being the isotropic case. The former corresponds to one dimensional diffusion in a plane sheet, the solution of which has been computed by McKay[15] and is plotted as curve a in Fig. 5.

The experimental points fall within the range of category (2) and correspond very closely to the upper limit of category (1), that is, to $D_z = 0$ (curve b).

The experimental curve thus has two interpretations. The interpretation according to category (2) requires a particular value of D_z/D_x, but we favour an interpretation which is a limiting case and which amounts to diffusion in two dimensions only. Unfortunately, it seems impossible at present to settle this problem by carrying out diffusion coefficient measurements along selected directions because of the instability of large single crystals in this composition range.

The agreement between the analytical solution for constant and equal values of D_x and D_y and the runs carried out over a narrow composition range (9·5–0 per cent Fe^{2+}), together with the gradual displacement of kinetic curves away from this solution for increasing initial compositions above about 10 per cent Fe^{2+}, suggested a model for reaction in which the diffusion coefficient is

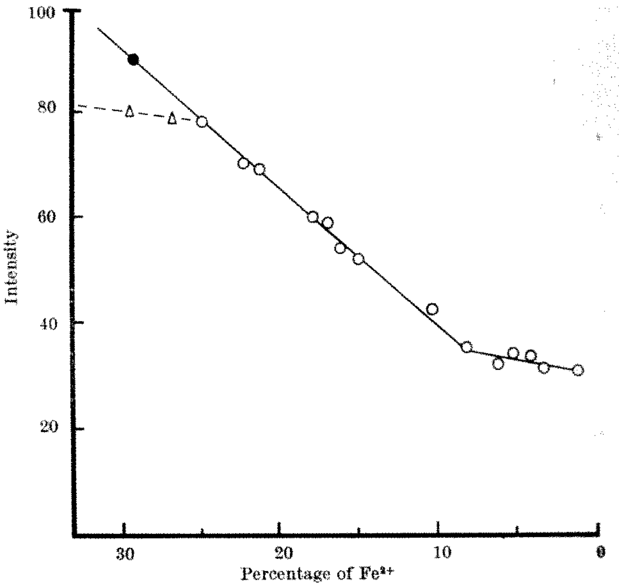

Fig. 3. Variation of the intensity of the (111) reflexion with composition.

concentration dependent and falls with decreasing Fe^{2+} content. To test this possibility diffusion coefficients for each starting composition were evaluated from the slopes of the plots in the parabolic region using the semi-infinite solid equation[6], and plotted against composition in Fig. 6. This plot indicates not only that D falls with decreasing concentration of Fe^{2+}, but also that below 9·3 per cent the diffusion coefficient is constant. This would explain why runs at or below this starting composition simulate curve *b* so well. (Below 9·3 per cent Fe^{2+} the diffusion coefficient measured in this way is the average of D_x, D_y and D_z.)

The uptake-time curve predicted by such a model was computed using Fick's law of diffusion

$$\frac{\delta c}{\delta t} = \frac{\delta}{\delta x}\left(D\frac{dc}{dx}\right)$$

which was linearized by introducing the variable

$$s = \frac{\int_0^c D dc}{\int_0^1 D dc}$$

and the resulting equation

$$\frac{\delta s}{\delta t} = D\frac{\delta^2 s}{\delta x^2}$$

was solved by numerical methods on an ICT 1905 computer for the case of a cube with the same boundary conditions as defined here, for initial compositions 24·6, 18·9 and 14·3 per cent Fe^{2+}. The computed curve for the 24·6 per cent Fe^{2+} case is shown as plot *d* in Fig. 5, yielding good agreement with the experimental points, but the fit of the theoretical curves for the other two cases was not so good. This feature will be discussed later. (The theoretical curves and experimental results of these two cases have been omitted from Fig. 5 to avoid confusion.)

The computer programme was designed to store the concentration profiles at successive points during the computation, which will correspond to successive stages during the reaction. These are presented in Fig. 7, together with profiles for the constant diffusion coefficient case for comparison. It is obvious that the profiles of the concentration dependent case are nearly horizontal in the "core" of the particle. The model thus predicts that as the chemical composition decreases it remains almost uniform over a considerable volume of the crystal, in contrast to the steep composition gradients predicted by the constant diffusion coefficient case. This phenomenon arises in the following way. During the first half of the reaction the greatest change in concentration in the magnetite crystal occurs in the surface layer. Because the diffusion coefficient will fall very rapidly in this layer during the early stages of the reaction it will behave like an insulator enabling the concentration in the "core" to remain near equilibrium during the whole of the reaction. The steep part of the gradient is confined to a smaller fraction of the volume of the crystal. This means that the broadening arising from strain induced by the change in lattice parameter with composition will be considerably less than that associated with the concentration gradient

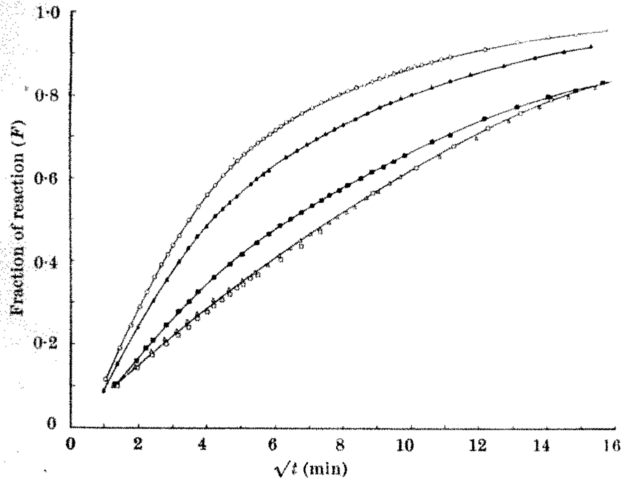

Fig. 4. Kinetics of oxidation of samples which had been previously oxidized to different compositions and then annealed at 190° C for more than 10 h. Kinetics were measured at 190° C and 150 torr O_2. Initial concentration (percentage of Fe^{2+}): ○, 24·6; ▲, 18·9; ■, 14·3; △, 9·5; □, 4·0.

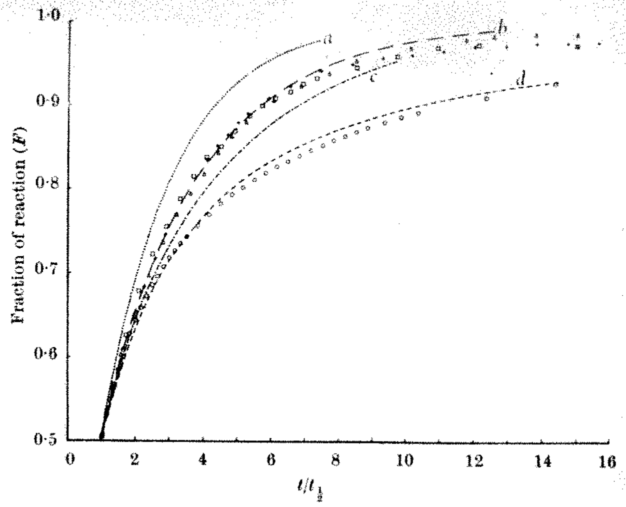

Fig. 5. Kinetics of oxidation as in Fig. 4 but plotted on a reduced time scale, $t/t_{1/2}$, along with theoretical curves for comparison. Below $F = 0·5$ all experimental points and theoretical curves almost coincide and so are omitted.

c, three
Dimensional diffusion, constant *D*. (See text for precise definition of boundary conditions.)

d. Three-dimensional isotropic diffusion computed for an initial composition of 24·6 per cent Fe^{2+} and for *D*, which varies with concentration according to Fig. 6.

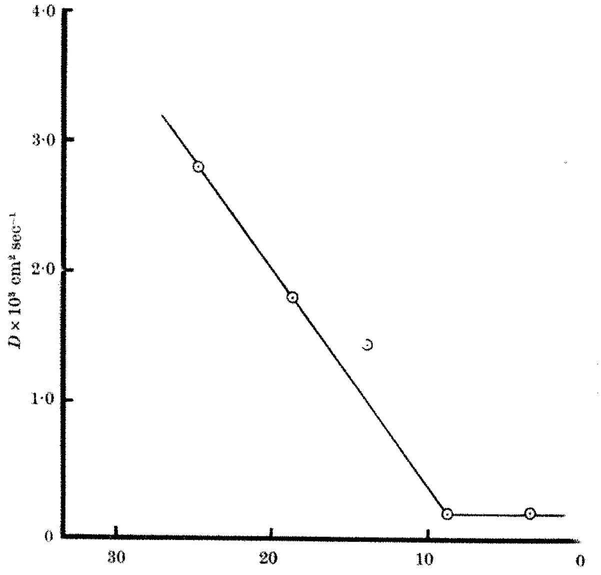

Fig. 6. Variation of diffusion coefficient of iron cations with composition at 190° C.

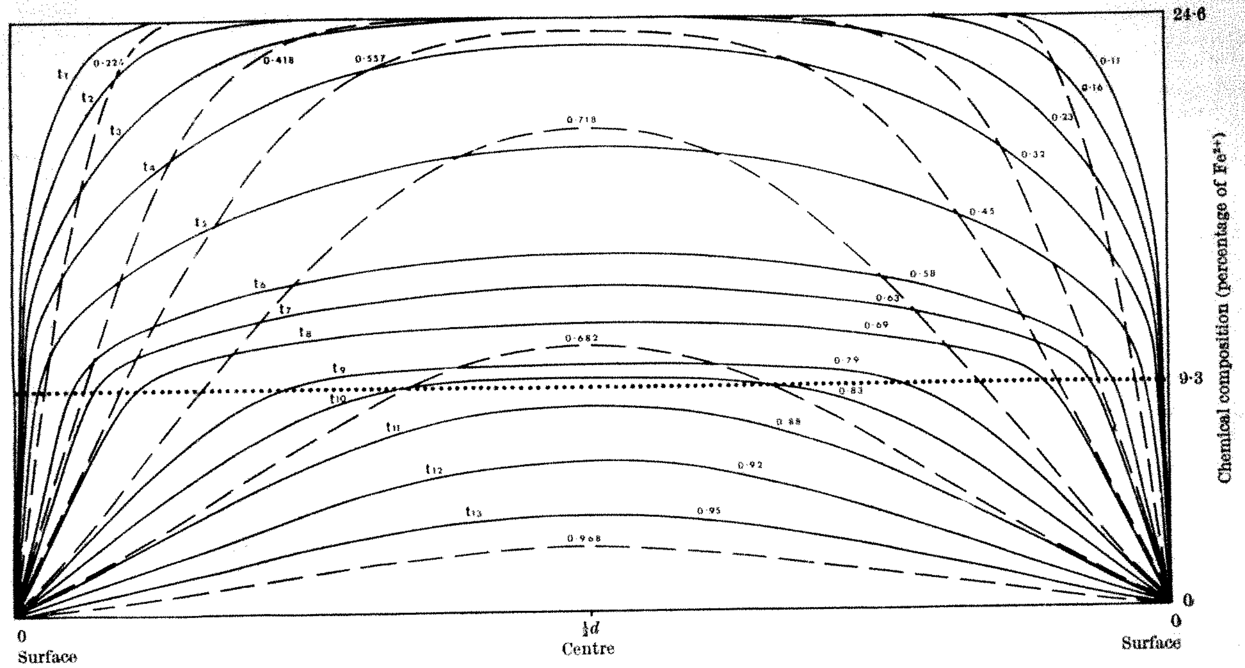

Fig. 7. Computed concentration profiles along a crystallographic axis of a cubic crystal of side d, at successive times during oxidation. - - - - Represents the solution of the equation for diffusion from a cube with a constant diffusion coefficient, —— represents the profiles for single crystal cubes of magnetite, calculated from the variable diffusion coefficient model. The other boundary conditions are the same in both cases and are defined in the text; they include isotropic diffusion throughout. Each curve is labelled with its corresponding F value.

in the constant diffusion case. The model thus explains the unexpectedly small amount of X-ray line broadening.

An inherent feature of the model proposed in this paper is a continuous change in non-stoichiometry from Fe_3O_4 to γ-Fe_2O_3. Discontinuities in composition in non-stoichiometry, however, are relatively common, but seem to be characteristic of compounds which change composition by an anion vacancy mechanism[10,11]. Compounds like magnetite which may suffer a change in composition through a cation vacancy mechanism are, however, thermodynamically more likely to give continuous changes in composition (that is, completely miscible solid solutions) because of the smaller size of the cation holes. We suggest that the success of this model in describing the kinetics over the whole composition range indicates that a continuous change in stoichiometry without composition discontinuities takes place during oxidation under these conditions. Whether this is also true under thermodynamically equilibrium conditions is another matter.

The model used for the computation of the theoretical curve for the kinetics of oxidation of the 24·6 per cent Fe^{2+} sample implies isotropic diffusion throughout the reaction whereas the experiment previously discussed indicated that when the composition falls below 9·3 per cent the diffusion is tetragonally symmetrical. The effect of not allowing for this feature in the model is likely to have only a small effect on the overall reaction kinetics when an initial composition as high as 24·6 per cent Fe^{2+} is used. It may, however, explain the small discrepancy between curve d and the experimental points for 24·6 per cent Fe^{2+}, and the gradual deterioration in fit between the experimental results of runs for decreasing initial compositions and curves computed with the isotropic concentration dependent model.

Colombo *et al.*[12] maintain that below 600° C magnetite never oxidizes to α-Fe_2O_3 unless α-Fe_2O_3 nuclei are already present. This is in contradiction to our observation. Even as low as 180° C particles larger than about 3000 Å have been observed to oxidize to α-Fe_2O_3, although according to the X-ray diagrams and the reducing conditions under which the magnetite was prepared α-Fe_2O_3 nuclei were absent. Furthermore, in a separate study of the transformation of γ-Fe_2O_3 to α-Fe_2O_3 Feitknecht and Mannweiler[5] have observed the transformation of γ-Fe_2O_3 to α-Fe_2O_3 at temperatures as low as 250° C. Colombo *et al.* have used natural magnetite in their experiments whereas we have used pure synthetic preparations. It has been observed[13] that some impurities, especially aluminium, stabilize the γ form of Fe_2O_3. Because natural magnetite may contain impurities in solid solution and in amounts which may vary from one locality to another, it is invalid to extrapolate its behaviour to that of pure Fe_3O_4.

Egger and Feitknecht[4] assumed that in the larger particles (over 3000 Å in diameter) spontaneous nucleation of α-Fe_2O_3 occurred because of greater lattice strain during the oxidation. The model proposed here for the mechanism of the oxidation to γ-Fe_2O_3 explains why this lattice strain should arise. The very low concentration gradient in the core of the magnetite particles during oxidation causes most of the change in the lattice parameter to be confined to a thin surface layer. The strain thus generated can be accommodated more readily in small particles, but above a certain critical particle size the unequal contraction within the surface layer causes the lattice strain to reach a level sufficient to activate the nucleation of the more stable α-form.

As far as we are aware, this is the first reaction of its kind which has been fully characterized and we would like to draw attention to the fact that this was made possible by a detailed analysis of the kinetic data in conjunction with the X-ray diffraction method.

Structural Units in Chromatin and their Orientation on Membranes

by
H. G. DAVIES
J. V. SMALL

Department of Biophysics,
King's College,
University of London

A recent theory indicates that chromatin contains a structural unit, common to many vertebrate cells, arranged in a manner rather like the molecules in a liquid. More or less random in the interior, the unit was recognized because it forms ordered layers of definite geometry at the surface of the nucleus and monolayers confined by membranes in the cytoplasm.

AFTER cell division the DNA in the chromosomes of the interphase nucleus or the chromatin may undergo replication, or its genetic message may be transcribed into RNA. There is evidence[1-6], based on uptake of radioactive precursors and known physiological activity, which suggests that in cells or regions of cells where the concentration of DNA is relatively high, in chromocentres, condensed chromatin or heterochromatin[7], these metabolic activities are much less pronounced than in more diffuse or extended-state chromatin. Such variation in concentration may be accompanied by variation in structure, and hence repression and derepression of genes may have a structural basis. We therefore suppose that a knowledge of the structure of chromatin, together with biochemical studies (for example, refs. 4, 8 and 9), will eventually lead to a better understanding of the factors controlling nuclear activity in the cells of higher organisms. This article summarizes our earlier data and describes new electron microscope observations of the structure of condensed chromatin, identified by its electron-staining properties and by a comparison with images obtained from light microscopy of sections stained for DNA with the Feulgen reaction.

There have been several recent reports, based on electron microscopy of thin sections, of structures associated with the nuclei of certain mammalian leucocytes and thymocytes, variously referred to as nuclear blebs, pockets, loops or projections. These were found in lymphocytes[10,11], neutrophilic granulocytes[10,11] and monocytes[11] in peripheral blood of normal humans; in immature granulocytes[12-15], monoblasts[14] and cultured lymphoblasts[16] from human leukaemic patients, some undergoing chemotherapy; in neutrophilic granulocytes[17,18] from humans with an abnormal chromosome number; in thymocytes from normal guinea-pig[19] and human foetus[20]; also in lymphoblasts from Burkitt's tumour[21-23] and cells cultured from it. These nuclear structures are therefore a more or less common feature of both the lymphoid and myeloid[24] elements of the blood. Similar structures were also reported[25,26] in the myeloid cells of two amphibia, in the interphase nucleus and mitotic chromosomes of polychromatophil erythroblasts and in mature erythrocytes from the newt *Triturus cristatus*; also in a granulocyte from frog, *Rana esculenta*. The nuclear projections in cells from newt, because of similarity in staining properties to condensed chromatin, were thought to consist of sheets of chromatin limited on both sides by the nuclear envelope, and were therefore called the envelope-limited sheets of chromatin or, simply, the sheets. The variously termed structures associated with the nucleus, referred to here, seem to have a similar morphology. The remarkable feature[26] of these sheets of chromatin is their approximately constant width, between about 300 Å and 500 Å depending partly on methods of preparation. A second finding[27,28] in the nuclei of certain cells, including those from tissues other than blood, is that the condensed chromatin immediately adjacent to the nuclear envelope is organized into layers. In newt cells these layers have similar dimensions to the sheets. These numerical data have led to the theory[27,28] that condensed chromatin contains a structural unit common to many vertebrate cells. The unit has been recognized primarily because of this tendency to form layers of definite dimensions adjacent to the nuclear envelope. In certain blood cells the layers give rise to sheets with similar dimensions extending into the cytoplasm. In the interior condensed chromatin, that is in regions away from the nuclear envelope, the same structural unit is present and apparently more or less randomly oriented[28]. The concept of an orderly arrangement near the surface of the cell nucleus induced by the membrane closely resembles the concept of the crystalline layer at the free surface of a liquid, put forward by Bernal[29] in a new theory of the structure of liquids.

Electron Microscopy

We have now found envelope-limited sheets in myeloid cells from two further classes of vertebrates, namely, birds and cyclostomes, and the study of their fine structure which we report here supports the theory we have just outlined. Cyclostomes are particularly interesting because they are the most primitive of the vertebrates.

To aid in interpreting the electron micrographs, to explain terminology and make clear the relationship between sheets and layers, our findings are shown schematically in Fig. 1. It has to be appreciated that the appearances in electron micrographs depend on the way the section is oriented relative to the specimen. Tilting the section in the microscope has been used[27] to elucidate the three-dimensional structure in it. When the plane of the section is normal to the plane of the sheet, as, for example,

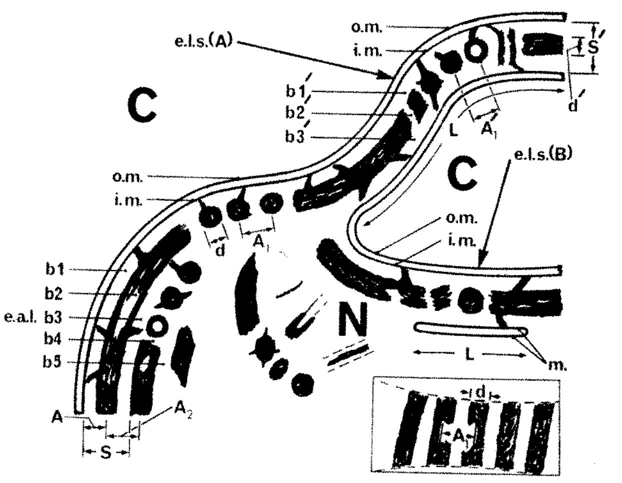

Fig. 1. Schematic diagram showing the envelope-limited sheets (e.l.s.) at (*A*) and (*B*), of length (*L*) with plane of section normal to sheet. i.m., o.m., The inner and outer membranes of the nuclear envelope. Bands $b1'$, $b2'$ (width d') and $b3'$ are seen in the sheet of total width S'. A_1' is the spacing of granules of diameter d' seen in $b2'$. The envelope-associated layers (e.a.l.) appear as bands $b1$, $b2$, and so on; S is the total width of bands $b1+b2+b3$; d is the width of the dark band or the diameter of the granules when well defined and A_1 is their separation; A_2 is the separation of bands $b2$, $b4$. A is the distance separating centre $b2$ from i.m., and $S \sim 2A$. N is nucleus, C is cytoplasm. Inset shows an envelope-limited sheet in face view, that is plane of section parallel to sheet.

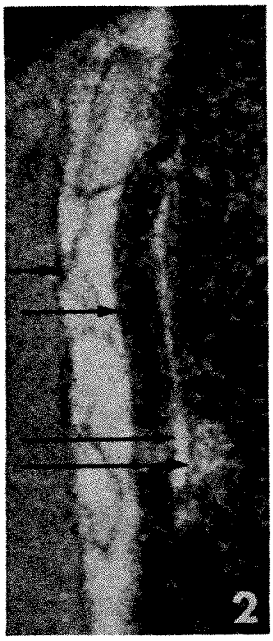
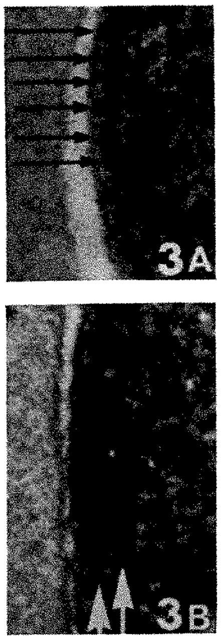
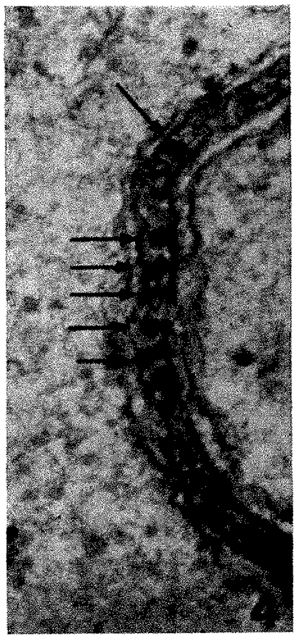
at e.l.s. (A) in Fig. 1, the membranes enclosing it appear as lines continuous with those representing the nuclear envelope. The sheet has a triple-banded appearance due to sectioning three layers. Band $b2'$ is relatively electron dense and when well defined it may appear as short segments or threads of width d', or as approximately equispaced granules of similar diameter. The appearance in electron micrographs was found to depend on orientation[28]. These elements, the band-segments and granules, are themselves composed of finer threads and similar threads cross the relatively less electron dense bands $b1'$, $b3'$, thereby joining $b2'$ with the inner membranes. Bands $b1'$ and $b3'$ are of approximately equal width. A second envelope-limited sheet is shown at e.l.s. (B). The sheets have a total width S'. Similar alternate dense and less dense bands $b1$, $b2$ and so on are found adjacent to the nuclear envelope[27], and by tilting, this appearance is found to result from sectioning envelope-associated layers, referred to simply as the layers (e.a.l. in Fig. 1). Frequently only $b1$, $b2$ and $b3$ are found, and this complex has been called the triple-structured band of width S (ref. 27).

Fig. 2 is an electron micrograph of an envelope-limited sheet of chromatin, with bands $b1'$, $b2'$, $b3'$, in a mature definitive erythrocyte from a chick embryo (17 day); it resembles that at (B) in Fig. 1. In a study of erythropoiesis in chick, where many thousands of cells have been observed, only six nuclei were encountered with such sheets. They occur infrequently and the length (L) is always small compared with the perimeter of the nuclear envelope seen in section. The average value of S' is 380 Å. In a previous study[28] of mature erythrocytes from adult chicken the total width S of the envelope-associated layers, $b1$, $b2$, $b3$, was 330 Å ± 18 Å after fixation in OsO_4 and embedding in methacrylate. Similar bands (Figs. 3A and B) have now been found in primitive and definitive erythrocytes from chick embryo, fixed in glutaraldehyde plus OsO_4 ('Araldite' embedding). In definitive erythrocytes from a 17 day embryo the values for parameters in Fig. 1 are: $S = 402 \pm 30$ Å (120 measured), $A = 208$ Å ± 25 Å, $d = 174$ Å, average (range 150 Å to 200 Å), $A_1 = 280$ Å $\pm$ 40 Å, $A_2 = 260$ Å $\pm$ 25 Å. These values, about 20 per cent higher than those found previously for chicken, indicate that the fixation procedure may affect the dimensions of the layers. Sheets have also been seen in the neutrophilic granulocytes (heterophils) in the spleen of embryonic chick.

In the neutrophilic granulocytes of the lamprey, envelope-limited sheets associated with the nucleus (Fig. 7) are very common, being found in up to about 15 per cent of nuclei in any section. Frequently, more than one sheet is attached to the nucleus giving it a bizarre appearance, very similar to that seen in human neutrophilic granulocytes and cells from the Burkitt tumour. The total length (L) of sectioned sheet is often comparable with the perimeter of the nucleus. In sections normal to the sheet there are bands similar to $b1'$, $b2'$, $b3'$ (Fig. 1) and in certain regions only (parts of Figs. 4 and 5) band $b2'$ is composed of well-defined granules. Measurements made on one animal give d' average = 170 Å (150 Å–210 Å), $A_1' = 300$ Å ± 23 Å. The granules have a variable appearance similar to that previously reported[28] for the granules in the envelope-associated layers and the interior condensed chromatin of mature erythrocytes from lamprey. Occasionally they appear hollow, that is annular, and projections may be seen in Figs. 4 and 5 radiating out connecting them with the inner membranes. The value of S' in the same animal is 365 Å ± 21 Å (thirty-six sheets). When the plane of the section is more nearly parallel to that of the sheet (Fig. 6 and inset to Fig. 1), well-defined short bands, straight or slightly curved, are seen lying in groups parallel to one another. These bands, about 170 Å in diameter, centre to centre separation about 300 Å, are themselves composed of finer threads and granules ranging in size down to 20 Å–40 Å. The arrangement of these finer threads, of molecular dimensions, has not yet been elucidated. They sometimes run at an angle to the 170 Å band making it resemble a coil. When the section is tilted ± 22° in the electron microscope the groups of 170 Å bands are still distinguishable but the finer details in each 170 Å band are altered. Envelope-associated layers (bands) lying adjacent to the nuclear envelope are also seen in lamprey neutrophilic granulocytes and resemble the bands already described ($b1'$,







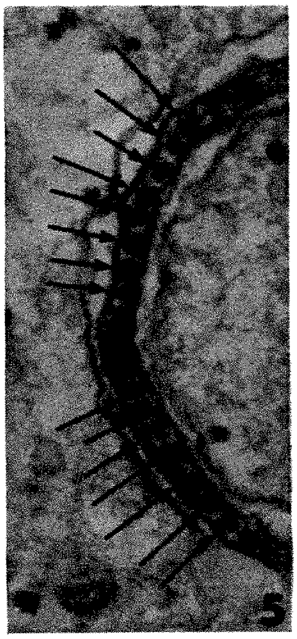


Fig. 2. Electron micrograph of mature erythrocyte from 17 day chick embryo showing an envelope-limited sheet cut normally: compare with e.l.s. (B) in Fig. 1. Membranes are arrowed, the cavity between the pair comprising the nuclear envelope being distended. (× 112,000.) All electron micrographs are of cells fixed in buffered glutaraldehyde followed by OsO_4, embedded in 'Araldite', stained in uranyl acetate and lead citrate, photographed in a Siemens 'Elmiskop 1'.

Fig. 3. Electron micrograph of mature erythrocyte from 17 day chick embryo showing the envelope-associated layers cut normally: compare e.a.l. ($b1$–$b5$) in Fig. 1. In A, arrows point to "granules"; in B, arrows indicate dense bands $b2$, $b4$. (× 112,000.)

Figs. 4 and 5. Electron micrographs of parts of two sheets from neutrophilic granulocytes of lamprey (*Petromyzon fluviatilis*); the plane of the section lies normal to the sheet; arrows indicate "granules"; see also Fig. 1. (× 105,000.)

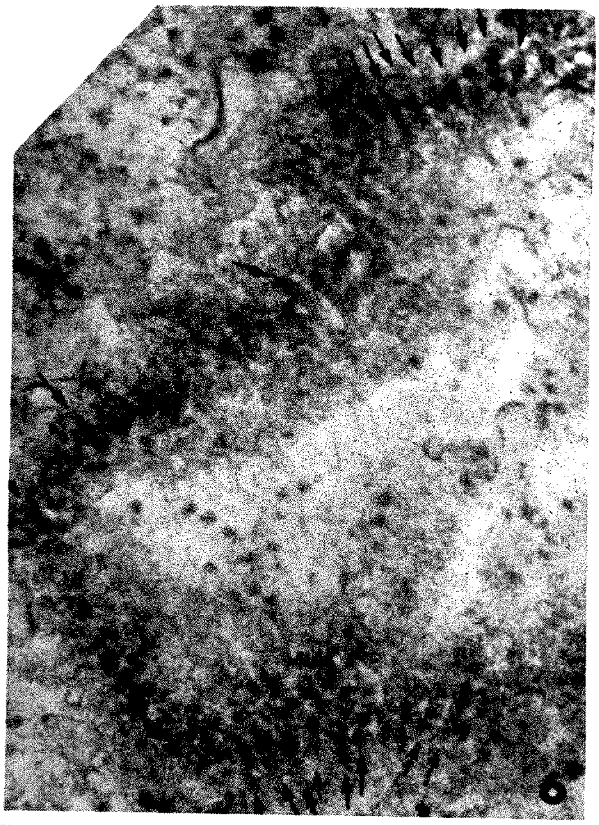
and so on in Fig. 1) in the sheets. In the material studied so far, however, they are not as well defined as those found previously[28] in mature erythrocytes from lamprey where the triple-structured band has a width $S = 346$ Å. We attribute this to difficulties in preservation. Envelope-limited sheets have also now been found in mature erythrocytes from lamprey.

Structural Unit

Summarizing certain of our measurements, in chicken erythrocytes S' is 380 Å and S is 402 Å, while in granulocytes from lamprey S' is 365 Å and in the erythrocytes S is 346 Å. This shows that the widths of the sheets (S') and triple-structured layers (S) are all very similar to one another and to the widths previously found in certain mammalian and amphibian cells. Consequently, the data support the theory that the chromatin in these cells contains a common structural unit and that the envelope-limited sheets are derived, by processes not yet fully understood, from the envelope-associated layers. The possible physiological role of the sheets is unclear, but where they extend into the cytoplasm they increase the area of chromatin in contact with it[11].

Consider now the nature of the structural unit which forms the sheets and layers and gives rise to the bands seen in the electron micrographs. It was at first suggested[26] that an envelope-limited sheet of chromatin was formed by folding a thread, about 400 Å in diameter, on the surface of a membrane, so as to form a sheet of equal width. When the sheets were found[27,28] to have a banded structure similar to that of the layers near the interior membrane of the nuclear envelope, this hypothesis had to be modified. Observations[28] of the envelope-associated layers and other more interior regions of the condensed chromatin in the nuclei of mature erythrocytes from lamprey and adult chicken, as well as in certain cells from newt spleen, suggested, as the structural unit in them, a thread of diameter between about 130 Å and 230 Å, the value depending partly on fixation. The dark bands in Fig. 3*B* arise from threads lying one above the other in planes parallel to the optic axis. When the axes of the threads are parallel to the optic axis the resulting end-on views give rise to "granules" (Fig. 3*A*). Sometimes end-on views were annular in shape suggesting that the thread is a hollow cylinder, that is a microtube. To account for the separation of the dark bands and granules both from one another and from the membranes, it had to be assumed that there were projections arranged along the threads or microtubes. Finer threads could indeed be seen in the micrographs crossing *b*1, *b*3 and so on.

These data on the fine structure of the sheets confirm and extend the hypotheses relating to the structural unit in condensed chromatin and its role in forming the sheets. Figs. 4, 5 and 6 show, respectively, end-on and face views of 170 Å threads about 300 Å apart. These values are similar to those found[28] for the threads (range 130 Å–230 Å diameter) thought to exist in the envelope-associated layers. In the embryonic chick erythrocytes measured here the thread-diameter (d) is also 170 Å and the separation (A_1) about 280 Å. The face views of the sheets in granulocytes from lamprey provide critical new information. Previously, because of the chance of overlapping structures in the section we could not rigorously exclude the possibility that the structural units in chromatin were not granules or spheres regularly arranged along axes. The appearance of the layers near the envelope is very similar to that seen in sections through certain virus crystals known to contain overlapping spherical units. In the sheet extending into the cytoplasm, however, there is only a single layer and we can be quite sure from the face views (for example,



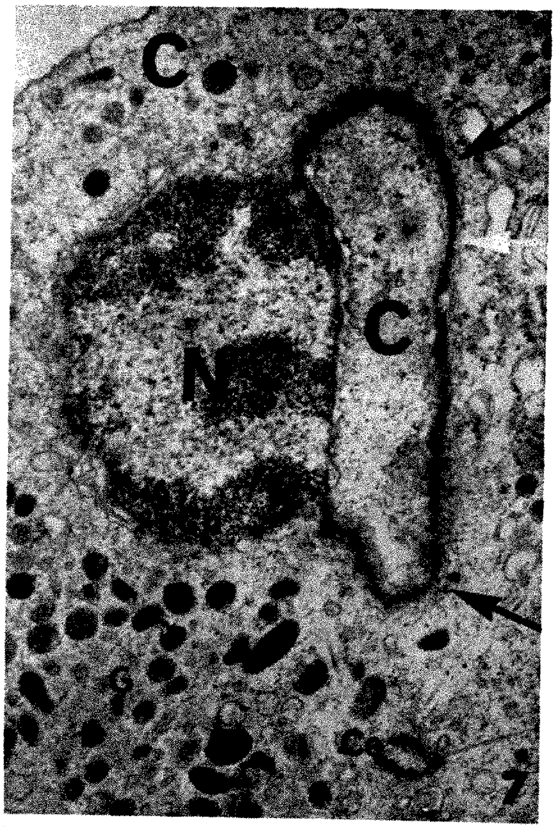


Fig. 6. Electron micrograph of that part of the sheet shown at lower arrow in Fig. 7. In this approximately face view, arrows point to the 170 Å bands (threads).

Fig. 7. Electron micrograph of a neutrophilic granulocyte from the lamprey; arrows point to an envelope-limited sheet; at the white arrow the plane of the section is approximately normal to that of the sheet, whereas elsewhere the sheet is cut at an angle giving approximately face views (see inset to Fig. 1 and Fig. 6). *N*, Nucleus; *Ch*, one piece of condensed chromatin; *C*, cytoplasm; *Ce*, centriole; *G*, granules. (×15,000.)

Fig 6) that the unit in it is threadlike We infer, as we had previously supposed, that the unit in the envelope-associated layers, being of similar dimensions, is also thread-like The projections which we have referred to may also be seen connecting 170 Å "granules" to the membranes in the end-on views (Figs 4, 5) and, as we noted, some end-on views are annular We have not shown that all the end-on views we observe are consistent with a tube and associated projections variously oriented with respect to the optic axis, and so we regard this model for the distribution of electron scattering material in the 170 Å thread and the finer threads which radiate from it as a working hypothesis

In the interior condensed chromatin, that is in regions away from the inner membrane, threads and granules, about 170 Å in diameter with internal fine structure, are common in both lamprey granulocytes and mature erythrocytes of embryonic chick They appear to be randomly arranged There are also still finer threads and granules All electron microscopists are aware of the fibrillar–granular elements of chromatin and have reported a range of diameters, about 20 Å to several hundred angstroms (see refs listed in ref 28) It has been shown[28] that some of these variations result from overlapping of the structures within the section thickness and there is possible variation due to distortion during preparation and to partial sectioning Because of these factors it is difficult to prove conclusively that condensed chromatin contains a structural unit of unique diameter, but there is no doubt that there is a very close similarity between the threads we are able to recognize clearly on the membranes and those found randomly arranged in the interior

Finally, we do not know what are the arrangements of the molecules in the structural units in condensed chromatin, although we can make certain suggestions There are various reasons[31] to be confident that in chromosomes and the nucleohistones derived from them the DNA is coiled or folded The problem is how this is effected, and various ideas have been put forward that in nucleohistone the DNA molecules are coiled around one another and linked by histone bridges[31] or from new X-ray diffraction data[30] on nucleohistone that the DNA forms a coil (super-helix) of diameter 100 Å, pitch 120 Å, that in the threads isolated from nuclei the DNA is coiled with histone to form a super-coil diameter 200 Å–300 Å (refs 32, 33) or that these same threads are formed from two parallel 100 Å threads each containing randomly folded DNA and histone[34] Our data suggest that the 170 Å threads in intact nuclei are probably tubular, which supports the concept of a superhelical configuration for the DNA We cannot, however, exclude the possibility that the molecular organization in the intact nucleus may be more complex For example, the DNA molecules may contribute to the formation of the projections from the 170 Å threads Quite likely it will be possible to define better the structural unit by further studies of the sheets which should be regarded as monolayers confined by membranes

One of us (J V S) is the holder of a Science Research Council award We thank Sir John Randall, Professor M H F Wilkins and Dame Honor B Fell for support and encouragement, and Miss Margaret Blade for technical aid

Gene Duplication and the Evolution of Enzymes

by

The relationship between structure and function of proteins makes it unlikely that a new enzyme activity can evolve unless the genome contains extra DNA with suitable coding properties such as is provided by the duplication of a gene for a functionally related enzyme. Evidence from the Annelida suggests that their diverse phosphagen kinases evolved in this way

SEVEN different phosphagens (Fig 1) have been found in the muscles of the Annelida, sometimes more than one occurring in a single species The group is thus unique in the animal kingdom, where all other phyla contain only arginine (in most invertebrates) or arginine and creatine (in the groups leading to and including the Chordata) It is nowadays realized that small metabolites such as the phosphagens have the disadvantage, for evolutionary studies, of being remote from the genome, their nature is determined by the interplay of enzyme systems within the organism. The enzymes themselves, on the other hand, are directly related to the genome and their comparative biochemistry is a true reflexion of genetic differences.

While the mutation of a gene could be described only in terms of gross results, such as changes in size or colour, it was possible to believe that evolution proceeded by the action of selection on organisms bearing different genes for such gross characters. In this view, some mutant genes were advantageous but most were disadvantageous. It was realized that one gene might modify another's action and hence its selective value, but the mechanism of these effects remained obscure[1]. In our present working concept, the unit of detectable mutation is a change in a single amino-acid of a particular polypeptide chain. (Behind this, not yet of great practical use, lies the change of a single nucleotide of a particular codon in the DNA.) At the same time, a protein is seen as a delicately balanced functional entity the integrity of which may be destroyed by one such change. It has thus become necessary to analyse the process of evolution in terms of protein structure and synthesis, the primary phenotypic effects which form the basis of the gross phenotype to be exposed to selection in the whole organism.

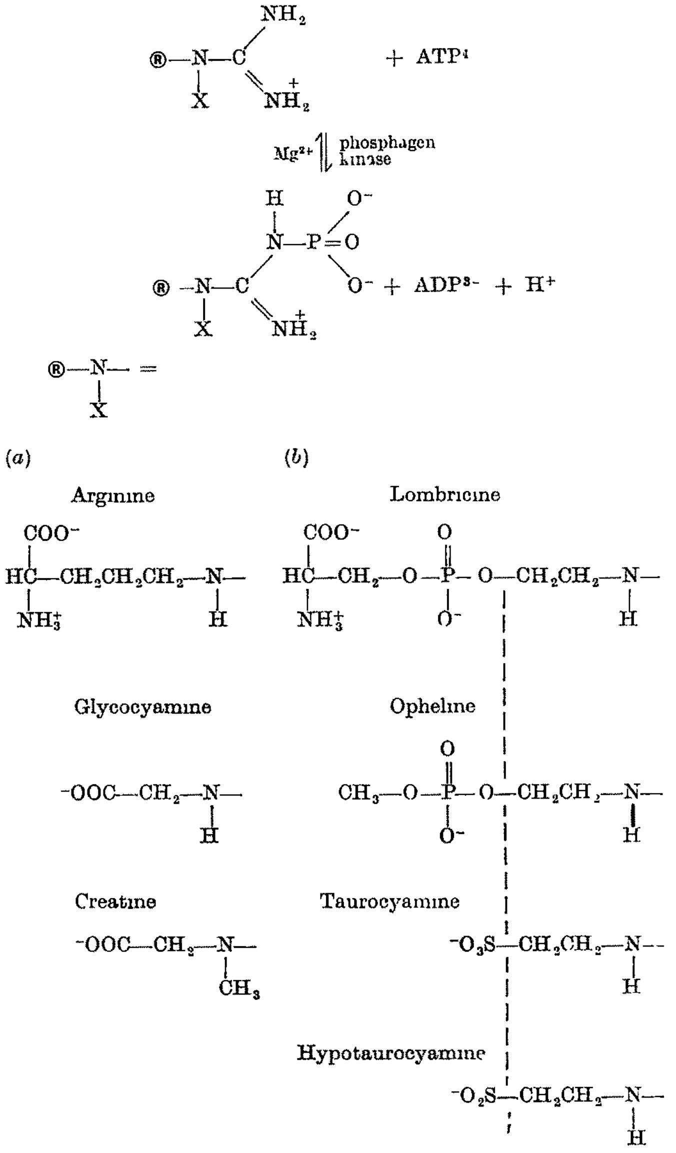

Fig. 1. General reaction for phosphagen kinases and formulae of the natural phosphagens. (a) Phosphagens whose kinases show high specificity, (b) phosphagens (all substituted guanidinoethanes) whose kinases show activity towards other members of the group.

Essential Enzyme Features

The establishment within a polypeptide chain of a small number of essential amino-acid residues orientated to form a catalytic entity must have been contemporaneous with the origin of life. A few types of catalytic sites can be recognized[2-4], corresponding to different classes of chemical change catalysed, in each of which specific amino-acid residues must occur in their correct place in the polypeptide chain and be maintained in their correct spatial arrangement through the tertiary structure of the molecule. All the basic mechanisms for catalysis in present day organisms probably already existed in the earliest forms of life, slight modifications in three-dimensional orientation of the catalytic amino-acids to permit the processing of new substrates appearing gradually during the evolutionary divergence of the various groups of organisms. A mutation resulting in change of a residue directly involved in catalysis would cause loss of enzyme function and, except in special cases, would always be lethal. A possible example is loss of one of the two essential thiols from the creatine kinase of mice with a fatal hereditary muscular dystrophy[5]. Changes in residues concerned in maintenance of the three-dimensional structure of the catalytic site might not always change the structure sufficiently to cause loss of function, so that selection against such changes would not be absolute.

The phosphagen kinases catalyse a phosphoryl transfer between ATP and a guanidino compound (Fig. 1) and enzymological evidence[6] supports the expectation that all have catalytic sites of one type. The differences between them involve other functions requiring particular amino-acids at particular positions in the enzyme molecule which can be listed as follows: (1) direct participation in the binding of substrates, (2) direct participation in specificity—the exclusion of unwanted substrate-like molecules to which the enzyme might be exposed in the cell, (3) direct participation in internal interactions permitting any conformational changes which might be associated with the catalytic process, (4) direct participation in interactions of a structural kind between the sub-units of the enzyme or between the enzyme and other macromolecules of the cell, (5) the maintenance of tertiary structure required in (1), (2), (3) and (4) and to adapt the catalytic site to the particular substrate, (6) the maintenance of tertiary structure required to confer stability on the enzyme in its particular cellular environment, which in turn may depend on the particular external environment of the organism.

Compensating Changes

A protein carrying out a particular function must be correctly constructed in many of its component parts in order to work at all. Moreover, residues may be critical for more than one function, a particular amino-acid having been selected because it satisfies all the functional needs. Adaptations of the protein molecule to encompass, for example, new substrate specificities would be likely to impair the correctness of the structure with respect to stability or in other ways. Thus even if a single mutation could bring about such an adaptive change, which is in itself unlikely, other changes in combination with the first change in the protein would almost certainly be necessary to restore its functional fitness. This phenomenon of compensating amino-acid changes has been shown in the *A* protein of the *E coli* tryptophan synthetase system[7] Here a glycine residue in one tryptic peptide and a tyrosine in another have been shown to be changed in certain mutants to glutamic acid and cysteine, respectively Both these changes result singly in loss of enzyme activity, but, when the two are combined, a partial revertant type is produced showing enzyme activity, although lower than that of the wild type Similar compensation has been shown in *E coli* alkaline phosphatase[8]

Comparison of the amino-acid sequences of a number of vertebrate haemoglobin and myoglobin polypeptides[9] showed that variation occurred in all but nine (about 6 per cent) of the residues, while the tertiary structure and function remained virtually the same Hence, 94 per cent of the residues have been non-essential One non-lethal change, however, could produce a cascade effect in the selection of counterbalancing changes elsewhere Thus it is particular combinations of residues which should be regarded as essential The idea of interdependent changes in residues underlies much of the discussion of globin variation by Zuckerkandl and Pauling[10]

To convert a protein to a new function or to adapt it to existence in a changed environment must in general require a number of mutations including both primary and compensatory ones Anfinsen[11] has suggested that, according to the metabolic importance, the selection pressure on enzymes will vary and hence their rate of evolutionary change A functional enzyme could, however, only acquire a new function as an extra by a slackening of specificity and changes in binding properties A new individual enzyme requires a gene of its own DNA coding for a once useful enzyme might have two immediate disadvantages its base sequence might be quite unlike that coding for any enzyme which could be of use to the organism and, at the point when its particular step in metabolism became redundant, mutations replacing amino-acids at the catalytic sites might have a strong selective advantage instead of being lethal This might not present a serious evolutionary problem Benzer[12] has shown, in phage, that variation in the ratio of forward back mutation rate at the same point is greater than can be explained by the possible nucleotide interconversions, selection may have established a "stable" sequence around the essential residues. giving them a low forward back mutation ratio A third disadvantage of "unused" DNA would, however, develop with time, its isolation from selective pressure would permit the accumulation of random changes in base sequence resulting in its inability to produce a protein resembling any enzyme It has been pointed out by Freese and Yoshida[13], however, that, because mutagenic substances are most active on single-stranded DNA, regions of the genome not involved in *m*RNA production would be to some degree protected, particularly in higher organisms where they may carry the additional barrier of a histone sheath This idea suggests that unused DNA might be kept in "cold storage", but furthermore that, before the most rapid evolution could occur, the probability of mutation would have to be increased by the process of producing a meaningless *m*RNA

Gene Duplication

The existence in the cell of "extra" DNA, as distinct from that "released" from its function because the protein for which it coded is redundant, is bound up with the concept of duplication of the whole or part of the genome This represents a departure from the essential processes of DNA replication and distribution to daughter nuclei whereby its quantity and nature are maintained in succeeding cell generations

Duplication of the whole genome has its own evolutionary significance In plants, vegetative reproduction allows the stabilization of polyploidy, and hermaphroditism eliminates the problem of interference with sex-determination, polyploidy is an essential feature of the evolution of this group[14] and has been widely studied Muldal[15] has compared chromosome counts for a number of oligochaete annelids and shown that those species which are parthenogenetic show various increases in ploidy above that in hermaphrodite species He also suggests that the latter are only secondarily diploid, having possibly arisen from the bisexual polychaetes[16] through tetraploid formation He points out that such events must lead to a freezing of the evolutionary change found in cross-fertilizing organisms Such a process may sometimes be reversible, as in the suggested origin from various ancestors among polyploid hermaphrodite fish of several vertebrate groups which subsequently adopted bisexual reproduction[17]

The theoretical advantages of the duplication of small parts of the chromosome was appreciated before the days of molecular biology Huxley wrote in 1942 that "small 'repeats' of this type constituted the chief method by which the number of genes is increased, thus providing duplicate factors and the opportunity for slight divergent specialization of homologous genes, giving great delicacy of adjustment"[18]

The occurrence of gene duplication was long ago recognized in *Drosophila* from gross genetic analysis of the *Bar eye* gene, which had the property of giving rise to normal and "*double Bar*" eyes in crosses where only *Bar eye* would have been expected and with a frequency far above that of mutation[19] The phenomenon of unequal crossing-over following occasional incorrect pairing in the *Bar* region was postulated to explain these results, and Sturtevant[19] believed *double Bar* to be a duplicated form of *Bar*, while the revertants had lost the gene altogether Bridges[20] found that numerous small duplicated regions could be detected in preparations of *Drosophila* salivary chromosomes, and discovered[21] that *Bar* was one of these, while *double Bar* showed the same region triplicated He realized that the no-gene concept for the wild type did not accord with the origin of *Bar* by a normal mutation Unequal crossing-over between two duplicated genes giving rise to a single and a triplicated gene, that is to normal and *double Bar* (Fig 2), is then achieved without the unlikely event of synapsis of lengthy non-homologous regions of the chromosomes[22] Such homologous unequal crossing-over does not explain the origin of a tandem duplication but can account for its development into multiple replicated regions The nature of primary duplication events, which may have occurred in the past, is a subject for conjecture based on cytogenetic evidence for possible modes of reorganization of the chromosomes Genetic investigations of the mechanism of tandem duplication[23,24] have dealt only with secondary duplications in regions of the chromosome consisting of pseudoalleles, arrays of genes with a fair degree of homology being the product, presumably, of earlier unexplained duplication events It was shown[25] that the occurrence of homologous unequal crossing-over within such a series did not induce non-homologous unequal crossing-over in adjacent regions of the chromosome

Usually, duplications must be detected a very long time after their arising, when their relative positions on the chromosome may have been altered by subsequent rearrangements and can thus provide small clues to the nature of the original events Possible mechanisms for the origin of duplicated genes, based on cytogenetic evidence for types of chromosome rearrangement, have been reviewed[26] These lead to the duplicate gene being sited in various parts of the genome relative to the original gene, and may be classified into four groups, with duplicate genes (1) adjacent, (2) close together in the same chromosome arm, (3) in different arms of the same chromosome, (4) in different chromosomes From the evolutionary point of view, the first two groups are probably the most important because they permit further (secondary) duplication to occur by homologous unequal crossing-over It must be concluded, however, that there is no evidence to suggest how any of the known gene duplications originated, although it may be inferred that the duplication by which the δ haemoglobin gene of primates arose from the β haemoglobin gene was of the adjacent type, on the basis of sequence analysis and phylogenetic evidence for its recent occurrence in conjunction with linkage data[27]

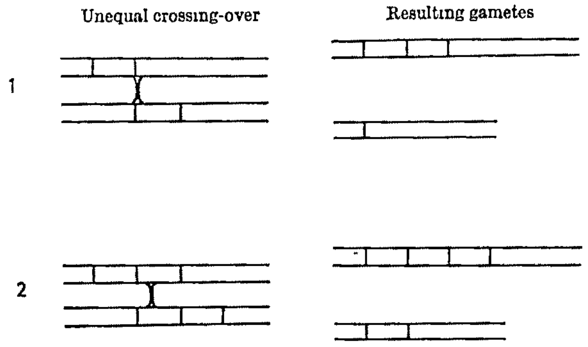

Fig 2 Unequal crossing-over at the *Bar* locus in *Drosophila melanogaster* (1) According to Sturtevant[20], non-homologous unequal crossing-over, (2) according to Bridges[21], homologous unequal crossing-over

Few of the mechanisms for gene duplication based on chromosome rearrangements directly yield tandem duplications This, together with a desire to explain partial duplication of the haptoglobin α-chain gene by a one step mechanism (as opposed to duplication followed by deletion, for example), may have prompted Smithies, Connell and Dixon[28] to discuss the implications of non-homologous unequal crossing-over as a source of primary duplications and partial duplications The mechanism is not new but this comprehensive treatment is probably responsible for its great popularity with biochemists interested in evolution We have found no evidence for its occurrence It is often confused with homologous unequal crossing-over, for which there is good evidence Until molecular genetics has thrown considerably more light upon the chemistry of crossing-over—in particular on how much homology is necessary for it to occur—non-homologous crossing-over should be treated with much greater scepticism

As a result of a survey of the properties of aldolase enzymes in a wide range of organisms, Rutter[29] proposed that the A and B isoenzymes in the rabbit, which can be distinguished by means of kinetic parameters, are the products of genes derived in the past by duplication of an ancestral gene Our scheme for the evolution of the annelid phosphokinases is based on what is probably still the only evidence for gene duplication giving rise to enzymes with different substrate specificity in different species—one essential feature of divergent evolution

Duplication of a gene can result in the release of one of the duplicate genes from selection while the other provides a viable phenotype The subsequent possibilities are the same as those for the DNA no longer used because the enzyme is no longer required by the organism, except that there would be no initial selective advantage in loss of enzyme activity or other aspects of the original "tailor made" structure These considerations make released DNA of this kind a very favourable material for the development of enzymatic capacities which are new but related to that of the original gene Related activities might include the further metabolism of the product of the original enzyme, or the parallel metabolism of related substrates prevented by the specificity of the original enzyme For a phosphagen kinase, mediating the reversible transfer of the terminal phosphoryl group of ATP to a compound which forms a dead-end storage product for chemical energy (Fig 1), only the latter can apply

Evolution of Phosphagen Kinases

In effect, a phosphagen kinase mediates a complete metabolic pathway, if its substrate is changed, new enzymes are not required to deal with the products of the reaction Adaptation of an organism to the use of a new phosphagen kinase would depend on the presence of the new enzyme and the availability of the new phosphagen The latter can most probably be provided by means of metabolic pathways commonly found in animals, arginine, the only guanidino amino-acid of protein, occurs universally and all other phosphagens are formed by transamidination from it (see formulae in Fig 1) The non-guanidino part of the molecule may most frequently be derived from general amino-acid metabolism Additional evidence for the presence of the appropriate kinase being the limiting factor in the use of a particular phosphagen is derived from the fact that in addition to all those animals which use any phosphagen other than arginine, many annelids contain appreciable quantities of more than one guanidine but only use one as a phosphagen[30]

Once duplicate genes have been formed, two other processes besides point mutation might be mentioned as potentially contributing to their divergence The first might occur in any DNA, whether duplicated or not, and has the effect of duplicating or deleting small groups of bases The mechanism is based on physical studies made by Lerman on DNA-acridine complexes[31] His results were compatible only with an intercalation model for the complex, he pointed out that in higher organisms local regions of the homologous chromosomes after synapsis could be out of register by one or several base pairs if intercalation of this kind had occurred randomly, and that crossing-over in such regions would result in deletion and reciprocally, duplication of the number of bases out of line Although there is little evidence in favour of whole genes undergoing non-homologous pairing, identical bases are not required at the actual point of crossing-over Two tryptophan synthetase mutants with an amino-acid difference can give recombinants having a third amino-acid at this point[7], indicating recombination within dissimilar codons When amino-acid sequences of related proteins are compared, amid regions of similar sequence, single extra or missing residues are frequently found[32,33], Lerman's mechanism would exactly account for this phenomenon

The second process for modification of the gene applies only in the case of adjacent duplicate genes, and has been suggested by Wagner and Mitchell[34], Horowitz[35] and recently by Comings[36] as a source of apparent multiple mutation It might sometimes have happened that recombination between large parts of two duplicate genes by unequal crossing-over gave rise to a functional new protein Such events would be necessarily linked to changes in the number of duplicate genes

If it is assumed that the ancestral annelid possessed arginine kinase, as is the case with most invertebrates, duplications resulting in two or three arginine kinase genes might be followed by various kinds of evolutionary divergence (Fig 3) A modern descendant may still possess arginine kinase either alone or with one or more homologous enzymes using other phosphagens as substrates Alternatively, after the evolution of a second kinase was completed, the ancestral arginine kinase activity might have been lost and replaced by one or more other kinase activities It seems unlikely that modern forms should continue to possess several genes coding for identical arginine kinases, for, making the reasonable assumption that one gene can provide all the enzyme required by the organism, the surplus genes would tend to be inactivated

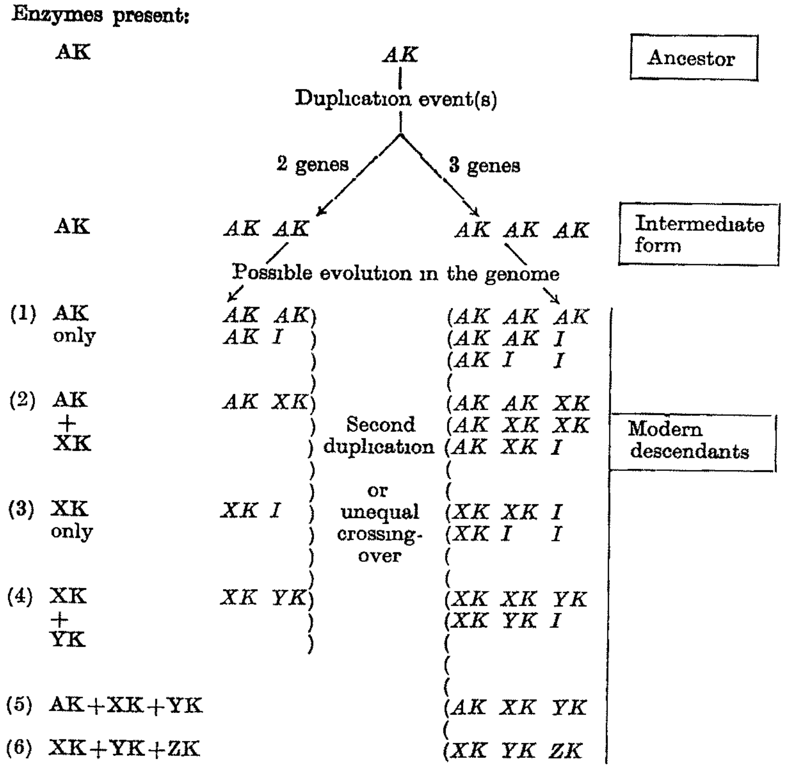

Fig 3 Theoretical scheme for the evolution of phosphagen kinase enzymes subsequent to the duplication of an ancestral arginine kinase gene Symbols AK, arginine kinase, *AK*, gene for AK, XK, YK, ZK, any other phosphagen kinases, *XK*, *YK*, *ZK*, genes for XK, YK, ZK, I, inactive protein, or none, *I*, gene for I

by mutation. On the other hand, genes for isoenzymes of arginine kinase, with slight structural differences of advantage in particular tissues or under the control of different control systems, might very well be maintained by selection It also seems unlikely that modern forms should possess two genes coding for identical *X*-kinases, because this would indeed be a freak of convergent evolution, unless in stepwise duplication the second step occurred very recently Once again, the possibility of isoenzymes of *X*-kinase exists

In summary, duplication events could give rise to a diversity of homologous enzymes both within and between species of the descendants These might be isoenzymes dealing with one substrate or enzymes dealing with related substrates Further predictions about evolving enzymes would be that such features as substrate specificity or structural rigidity might be less absolute

Annelid Phosphagen Kinases

Information on the phosphagen kinases in a range of polychaete annelids is set out in Table 1 The second column shows whether the species has been found to possess arginine kinase activity Other phosphagen kinases which have been demonstrated are also listed, and the third column shows the total of different activities known for each species The fourth column contains information on kinase specificity obtained from studies with substrate analogues (D-arginine, homoarginine, glycylglycocyamine, δ-guanidino-*n*-valerate, L-α-amino-γ-guanidinobutyrate and L-canavanine sulphate), and the fifth, in the cases where more than one activity has been shown, contains information about the additive nature of the reaction in the presence of mixtures of substrates The latter information is of use in reaching a decision as to whether two separate enzymes deal with two different substrates as opposed to one enzyme of lower specificity In the last column, where it has been possible to apply this technique, starch gel electrophoresis results for the enzymes are noted.

It can be seen that actual results with polychaete annelids completely parallel the theoretical expectations and can in fact be explained by the hypothesis illustrated in Fig 3, where three homologous sections of DNA were postulated The maximum number of different activities found in one species was three, including arginine kinase in *Myxicola* (as in Fig 3, possibility 5) and excluding it in *Nereis* (as in possibility 6) In both cases, additivity has been only partially checked, but was found to occur with the substrate combinations tested The possibility therefore remains that only two enzymes, coded for by two homologous sections of DNA, could possess the activities found As discussed by Virden and Watts[37], however, the data of Thoai[38], Thoai *et al* [39] and Gaffney *et al* [40] on the specificity of kinases the substrate of which contains the guanidino-ethane group (Fig 1) make it clear that although specificity is low as between the members of the group, activity with other natural guanidines is almost entirely absent This would make it extremely unlikely that the GK and TK activities in *Myxicola* are functions of the same enzyme or the CK and TK in *Nereis* For *Nereis*, all possible paired activities are thereby ruled out, while for *Myxicola* the AK and GK might still be functions of one enzyme The activity of the *Myxicola* extract with glycocyamine was very high, 45 per cent of the arginine kinase level of activity, although the specificity with substrate analogues was shown to be lower than for most arginine kinases, the highest unusual activity, with D-arginine, was only 5 per cent of the arginine kinase level It seems reasonable to conclude that there are three distinct enzymes in *Myxicola*

Aphrodite and *Hyalinoecia* both have arginine kinase plus creatine kinase (possibility 2) and *Sabellaria* has arginine kinase plus taurocyamine kinase Until the latter species was investigated, it seemed that there might have been some evolutionary bias towards the AK and CK combination, which occurs also in two other major groups, the Tunicata[37] and the Echinodermata[41,42], suggesting that evolution from AK to CK may be simpler or more advantageous than from AK to any other kinase In this respect, as in others, it now seems that the Annelida

Table 1

Animal	Presence of kinases AK	CK	GK	TK	Total No	Specificity	Additivity (where more than one kinase present)	Isoenzymes

* Unpublished results.

must be distinguished from other groups The fourth possibility, two kinases neither of them AK, is represented by *Arenicola* and *Nephthys*

Sabella affords an example of the situation where no kinase other than AK is found, the first possibility This enzyme, however, showed a particularly low specificity toward substrate analogues, suggesting that this species, like the others, had an ancestor in which duplications occurred, and that it is also an example of evolution in action The indication of two AK isoenzymes in starch gel electrophoresis supports the view that *Sabella* is not a "living fossil" with only one kinase gene Possibility 3 is found in the case of *Branchiomma*, which shows only taurocyamine kinase activity, and in *Hermione*, with only creatine kinase Some reservation may be appropriate with *Hermione*, since the related species, *Aphrodite aculeata*, also found by Hobson and Rees to show only creatine kinase, was subsequently found to possess a relatively labile arginine kinase[37] If results for for phosphagens[17] are considered, a long list of species with only one phosphagen, differing from phosphoarginine, could be made In those species where kinase activities have been measured, however, agreement with the phosphagen results is not good, the enzyme measurements being clearly more sensitive and occasionally in conflict with those for the phosphagens[37]

The group specificity of enzymes towards phosphagens containing the guanidinoethane group, the fact that *Sabella* (AK), *Aphrodite* (AK+CK) and *Myxicola* (AK+GK+TK) were all capable of phosphorylating substrate analogues, and that a number of arginine kinases had a lower than usual stability are all features to be expected if the enzymes were still undergoing evolution

Evidence for multiple forms of the activities studied is not abundant Only three of the species possessed kinase activities powerful enough to be revealed by the rather insensitive methods used for staining after starch gel electrophoresis In all these, the activities found had migrated with medium velocity at *p*H 8 5 In *Nereis* the CK and GK activities were located in the same band indicating (in conjunction with the additivity of these activities) that the two enzymes had the same mobility In *Hyalinoecia* only AK could be demonstrated on the gel, and in *Sabella*, where no other activity had been shown, two arginine kinase bands appeared, one in the same zone as the activities in other species, and one of slightly greater mobility Including isoenzymes, more than three activities have never been shown in one species As it seems that the properties of molecular dimensions and charge upon which electrophoretic mobility depends may be closely similar in most of the enzymes, isoenzymes may occur which cannot be demonstrated under the conditions of electrophoresis used

In contrast to the diversity of phosphagen kinases found among the polychaete annelids, only lombricine kinase could be detected[43] among sixteen species of oligochaete annelids As previously mentioned, polyploidy is common in the latter group, accompanied by parthenogenesis At first sight, it seems paradoxical that, in a group of species known to have at least a double complement of genetic material, only one enzyme is found, whilst in a related group several homologous enzymes occur There are two main possibilities for the evolution of the oligochaete situation, either this group diverged from the polychaetes after the primary duplication of the arginine kinase gene and followed the same pathway as a polychaete in group 3 (Fig 3) or, alternatively, the extra gene making possible the evolution of lombricine kinase arose in the polyploidization The fact that no diversity of kinases has been evolved is witness to the great importance of recombination in evolution The mutation rate in the oligochaete genes is unlikely to be greatly different from that in the polychaetes, but regrouping of portions of changed genetic material is virtually absent in a parthenogenetic organism In consideration of this, it seems most probable that the oligochaetes and polychaetes diverged after the primary gene duplication and that polyploidization in the former group did not occur until after the evolution of lombricine kinase was complete

The hypothesis presented here for the origin of diverse enzymes following duplication of the appropriate material in the genome is in itself no novelty Its theoretical development, originally undertaken to examine its feasibility for the annelid phosphagen kinases, should also prove useful in understanding the evolution of other proteins Perhaps the most remarkable feature of the somewhat sparse data available for the annelid kinases is that, in addition to being in no way in conflict with the hypothesis, they afford illustration of almost all the possibilities predicted by it

R L Watts thanks the Spastics Society for support during the greater part of the preparation of this paper We also thank Professor P E Polani for much helpful discussion of the manuscript

LETTERS TO THE EDITOR

ASTRONOMY

Stimulation of Interstellar OH by Phonons

THE attempts which have so far been made to explain the observed features of the interstellar OH molecule cannot be regarded as entirely successful[1] The most interesting observations are the OH sources in emission, where it is clear that some form of maser action is involved Any theoretical model to explain these data must provide a mechanism for producing stimulated emission while also accounting for the formation and stability of the OH molecule under the conditions prevailing in the emitting region An optical pumping device involving absorption and re-emission at $\lambda = 3080$ Å in the $X^2\Pi \rightarrow A^2\Sigma^+$ bands was suggested by Perkins *et al* [2], but this process has recently been criticized by Solomon[3] It has been argued[3] that the OH would be dissociated faster than it would be pumped by ultraviolet absorption Solomon has in fact suggested that OH may form in the upper level of the Λ doublet by inverse pre-dissociation reactions taking place at a few thousand degrees Kelvin, but the possibility of other formation and stimulation mechanisms cannot be ruled out at the present moment

The possibility that OH may be closely associated with grains has so far not been seriously considered Recent observations by Ishida and Akabane[4] indicating a close coincidence between the isophotes of OH emission with those of optical absorption in *W*3 seem strongly to support such a view According to current ideas[5], interstellar grains consist of graphite flakes of radii $\sim 5 \times 10^{-6}$ cm from stellar sources which accrete mantles chiefly consisting of H_2O, in quiescent *HI* regions The outer ice mantles of the grains are quickly sputtered away[5,6] in shock fronts and *HII* regions where the gas temperature rises above a few thousand degrees. The end-products of the sputtering reaction cannot be specified definitely, but it is not unlikely that large quantities of OH might be liberated by this process It is also likely that free graphite surfaces will be very efficient in catalysing the recombination of OH in the manner discussed by Stecher and Williams[7] A considerable fraction of the OH formed in hot clouds may be able to diffuse into the graphite lattice and become trapped between the hexagonal layers The inclusion of OH as impurities would make them quite stable against dissociation by ultraviolet light It would also then be reasonable to expect that solid state effects would play a part in the stimulation of the OH molecule

The results of two recent experiments seem to have an important bearing on this issue

(1) It is found that acoustic microwaves may be greatly amplified in a semiconducting material provided currents involving supersonic electron drift velocities can be generated[8] In these conditions the electrons, which may be imagined as bunched together in the potential troughs of the wave, transfer their energy towards amplifying the acoustic wave

(2) Acoustic microwave phonons may be generated by electromagnetic microwaves and, conversely, acoustic microwave phonons may give rise to electromagnetic microwaves in conducting and semiconducting material[9]

The following sequence of events is proposed Thin graphite flakes of radii $\sim 10^{-6}$ cm containing OH impurities* are exposed to collisions with gas atoms in a shock front or an *HII* region where the kinetic temperature $T > 3{,}000°$ K Because of collisions the grains acquire angular speeds ω given by

$$\frac{1}{2} I\omega^2 \simeq \frac{3}{2} kT \qquad (1)$$

where I is the moment of inertia For a thin flake (thickness $\sim 10^{-7}$ cm) an angular speed $\sim 10^9$ Hz may be obtained quite easily in the regions we consider With respect to axes fixed in the grain the galactic magnetic field will have rapidly oscillating components and the process of diamagnetic relaxation will take place The details of this process have been discussed elsewhere[5] in relation to the problem of the alignment of grains The energy dissipated by such a process is expected to be largely in the form of low amplitude microwave phonons. It is also likely that a background microwave radiation at $\sim 10^9$ Hz would feed in low amplitude phonons at the same frequency (compare experimental result (2)) If the conditions necessary for experimental result (1) to hold are satisfied, these microwaves may be very greatly amplified in a maser-like fashion There is also some evidence to suggest that maximum amplification occurs for frequencies in the range 10^9–10^{10} Hz, very close to the frequency of the Λ doubling transition in OH (ref 8) The result will be a continuous pile-up of phonon states with energies close to that required for the excitation of the upper state of the Λ doublet Finally, from the experimental result (2) we would expect the microwave phonons to give rise to photons of the same wavelength which actually cause the population inversion in the OH impurities

The velocity of sound in graphite is $\sim 10^6$ cm s^{-1} Although this is close to the thermal velocities of conduction electrons in the grain, the production of systematic currents with drift velocities $v \sim 10^6$ cm s^{-1} would require external electric fields $E \sim v/\mu$, where μ denotes the electron mobility For ideal graphite $\mu \simeq 3 \times 10^6$ E S U (ref 10), but for impure samples it is considerably lower, for our case it may be reasonable to assume $\mu \simeq 10^5$ E S U (ref 11) The external electric field required is thus $E \sim 10$ E S U Such a field may be supplied by ~ 10 electrons residing at any time on a grain of radius $\sim 10^{-6}$ cm By considering the rates of arrival of electrons and protons at a grain surface, Spitzer[12] has shown that such a net charge is indeed likely in an *HII* region

The estimation of the energy output is difficult on account of several uncertain parameters involved The very small sizes, $\leqslant \sim 0\ 01$ pc, of the emitting regions would suggest that drastic compressions of the interstellar medium must be involved For our model it would suffice if this compression is chiefly restricted to the dust component The early work of Spitzer[13] suggests that such compressions of dust relative to gas may take place in the presence of intense radiation fields, which may be appropriate to clouds in *O* and *B* associations This is due to an attractive force which is set up between two dust particles, because each grain casts a "shadow" on the other and cuts off the radiation field in a small solid angle Assuming a compression of dust from an initial dimension of ~ 5 pc to $\sim 0\ 01$ pc, the dust density would increase from $\sim 10^{-11}$ cm^{-3} to $\sim 10^{-3}$ cm^{-3} The gas density may rise by a smaller factor, say, 10^2–10^3

According to the picture we have, the chief source of energy for the excitation of OH arises from the constant arrival of electrons at the grain surface It is the electrostatic force exerted by the impinging electrons which accelerates the conduction electrons to supersonic speeds, and these in turn give up their energy to amplify the 18 cm microwaves The arrival rate of electrons is

$$\sim n_e \pi r^2 v_e \qquad (2)$$

where n_e is the number density of ambient electrons, v_e is their thermal velocity and r is the radius of the grain

---

* We may assume that graphite flakes with a high impurity content possess the semiconducting properties required for experimental result (1) to be valid The impurities have the effect of separating the valence and conduction bands of graphite, and reducing the free carrier concentration

The rate of supply of energy to the conduction electrons is therefore

$$E \simeq n_e \pi r^2 v_e kT \text{ erg s}^{-1} \quad (3)$$

assuming that the entire kinetic energy of impinging electrons is transferred to the solid. With plausible values, $n_e \simeq 10^2$ cm^{-3}, $r \simeq 3 \times 10^{-6}$ cm, $T \simeq 10^3$ °K, $v_e \simeq 10^7$ cm s^{-1}, we obtain $E \simeq 3 \times 10^{-16}$ erg s^{-1} If an appreciable fraction of this energy is converted into 18 cm wavelength photons, the photon production rate will be $\sim 10^2$ s^{-1} grain^{-1}. With an estimated grain density of $\sim 10^{-3}$ cm^{-3} this would give a production rate of ~ 0 1 photons cm^{-3} s^{-1}, similar to the minimum output (assumed isotropic) of the stronger sources

A further linear compression of the dust by a factor $\sim 10^2$–10^3 would raise the total output of radio photons to $\sim 10^6$–10^8 cm^{-3} s^{-1} We may then be able to obtain very high brightness temperatures, $T > 10^{13}$ °K, for OH sources without requiring a collimation of the microwave output

A slight degree of collimation is to be expected in the microwave output if the highly anisotropic graphite flakes are aligned by a magnetic field The harmonic motion of the radiating dipoles will be largely confined to the hexagonal planes, and the scattered light profile of an individual grain will be strongly directed along the crystal axis We may therefore expect the microwave output to be directed more or less along the magnetic field It may also be possible to explain some of the polarization effects which have been reported in terms of the alignment of spinning grains The narrow widths of the observed OH lines may be understood as being because of the very low thermal velocities of the grains

I thank Dr E A Davis and Dr P A. Strittmatter for valuable discussions

Lunar Occultation of a Solar Active Region at 4 cm Wavelength

The solar eclipse of July 20, 1963, was observed from Ann Arbor, Michigan, using the 85 ft paraboloid telescope of the University of Michigan As observed from Michigan the solar eclipse was partial, however, the Moon completely occulted two discrete regions on the Sun—one near the east limb and the other near the west limb We observed the lunar occultation of the eastern region At the 4 cm wavelength at which this occultation was observed, the pencil beam of the radio telescope had a half-power width of 5′ 95 of arc Drift scans were taken across the region before the occultation in order to find the position of the peak These scans indicated an angular size of about 3′ of arc and a position which was in agreement with the position indicated by Stanford λ 9 1 cm maps Thus the beam almost completely covered the discrete region, and the observations consisted in tracking the region throughout the period of occultation with the beam pointed on the peak of the region The occultation was observed in both immersion and emersion.

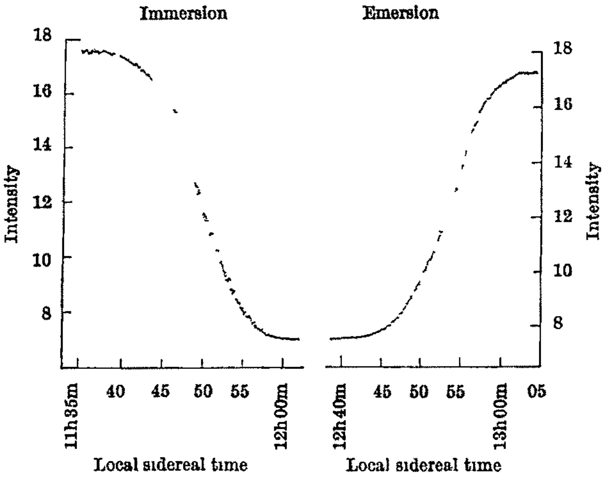

Fig 1 The curves of immersion and emersion of the eclipse of July 20, 1963 The radiometer intensity is in arbitrary units

Both analogue and digital records at intervals of 4 s were taken The occultation curves for immersion and emersion are shown in Fig 1 From the calculated positions of the Moon's limb at intervals of 4 s, we have determined the position angle and the velocity at which the Moon's limb moved across the source These calculations led to an independent determination of the position of the source It coincided well with the position of the region as given by the Stanford map at λ 9 1 cm

The strip-integrated brightness distribution was obtained by differentiating the occultation curve for both immersion and emersion The smoothed brightness distributions for immersion and emersion are shown in Fig 2 From the emersion distribution it seems that the source has a central component of angular size about 45″ of arc and a very weak outer component Furthermore, the distribution is not symmetrical, the intensity rises sharply on the east, and decreases rather slowly on the west side

From the derived brightness distributions, one can find the exact times of disappearance and reappearance of the peak of the active region These times in turn give the position of the peak with a precision of better than 5″ of arc Converted into heliographic co-ordinates the position thus obtained is N. 9°·5, E 52°·6 at 2200 hours UT This position is slightly displaced from the position of the associated sunspot as it appears on the Fraunhofer Institut map This is because the source at λ 4 cm is situated above the sunspot Indeed, assuming that the source is situated radially above the associated sunspot, the height estimated is found to be 14,000 km above the photosphere These results are in agreement with the observations[1] made earlier on λ 3 cm, and are consistent

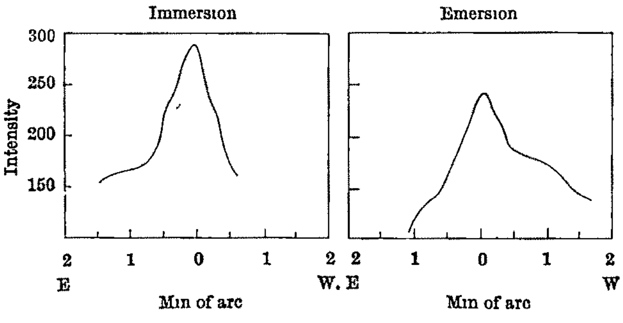

Fig 2 The derived strip-scan brightness distributions across the discrete region, zero of ordinate represents the position where the beam was pointed Directions of scanning for immersion and emersion are at angles of 23° and 4° 5, respectively, to the east–west diameter of the solar disk

with the theory of resonance absorption that has recently been proposed to explain the slowly varying component[2,3] According to this theory, resonance absorption at harmonics of the gyrofrequency in the strong sunspot magnetic field can explain the small size and high brightness temperature of the source at centimetre wavelengths This theory also indicates that the intense peak at centimetre wavelengths should lie above the associated sunspot

We thank Professor F T Haddock for permitting one of us (M R K) to use the 85 ft dish for these observations

PLANETARY SCIENCE

Sunspot Cycle and the Quasi-biennial Stratospheric Oscillation

Previous communications[1,2] reported observations from the southern hemisphere indicating an attenuation of the quasi-biennial stratospheric oscillation in the years 1963–64 The 24 to 26 month cycles of wind and temperature in the lower stratosphere, and of total ozone, weakened or vanished after a series of pronounced cycles[2,3] in the years 1955 to 1962 (which were characterized by high sunspot activity)

During recent years, quasi-biennial modes reappeared with a reversed phase in observations from many places The breakdown of the oscillation in 1963 had been linked[1] with a reduction of direct solar radiation in the southern hemisphere, following the injection of volcanic dust into the lower stratosphere during the eruption of Mount Agung, Bali (8° S , 115° E), in March 1963 Ebden[4] has since shown that a weakening and subsequent phase reversal in the quasi-biennial modes in 30 and 50 mbar temperatures at Ascension Island (7° 58′ S , 14° 24′ W , about 14,000 km west of Bali) commenced with a relatively sudden and sustained temperature rise which was compatible with the eastward spread of the dust and its radiation effects

Ramanathan[5] had already noted that in the long series of observations of total ozone at Arosa (47° N) from 1939 to 1963 breaks and phase shifts occurred in the quasi-biennial mode, about half-way between sunspot maxima. Because 1964 was a year of sunspot minimum an extraterrestrial influence on the oscillation is suggested

We present here further evidence to support a connexion of the quasi-biennial oscillation with sunspot cycle, including observations in the tropics north of the equator The curves in Fig 1 summarizing this evidence are based on time series of monthly means to which a suitable filter[1] has been applied to eliminate trend and annual waves The recent break in the cycles of total ozone at Brisbane (27 5° S) and Aspendale (38° S) in the southern hemisphere, where the ozone amplitude has been generally larger than in the northern hemisphere[6], can be seen The reappearance of a quasi-biennial cycle with reversed phase in 1965 is indicated Early Australian ozone observations with the old type Dobson spectrograph at Mount Stromlo, Canberra (35° S), in the four years preceding a sunspot minimum in 1932 also showed a markedly weakening biennial mode

In the longer records of 60 mbar temperature at Aden (13° N) and Hobart (43° S) the attenuation prior to the sunspot minimum in 1964 stands out clearly There is no discernible quasi-biennial oscillation for several years preceding the sunspot minimum in 1954 At Aden this means a break in secular continuity because the earliest records, before 1951, reveal a marked biennial mode The curve for the meridional wind component at 18 5 km ($\simeq$ 60 mbar) over Wilkes (66° S) on the coast of Antarctica —a corrected and extended version of one previously published (ref 1)—bears out the global nature of the

phenomenon, though with a reduction of amplitude At Macquarie Island (53° S) quasi-biennial cycles of the 100 mbar temperature continued after 1962 (ref 2)

In search of still earlier evidence, we collected all records (see legend to Fig 1) of sufficiently high pilot balloon ascents near the equator where, in the lower stratosphere annual and semi-annual waves in zonal wind are swamped by the quasi-biennial variations They can thus be recognized in scattered samples, each consisting of a few days of observations, as seen in Fig 1 in the plots of 19 5 km ($\simeq$ 60 mbar) zonal wind velocity in the 1908–33 epoch (on a level with the Aden temperature curve) The zonal velocity indicated by the dust veil from the Krakatoa eruption is also shown The connexion with sunspot cycle is brought out in these wind data in another way, by a broadly in-phase relation with the Aden curve, the time scales having been fixed relative to the sunspot cycle (the minimum *m*)

An association of amplitude fluctuation in the quasi-biennial oscillation of temperature and ozone with the single (about 11 yr) sunspot cycle suggests the influence of variable solar corpuscular emission This would, however, require a polar rather than an equatorial drive Lindzen[7] concluded that one can rule out an equatorial drive by radiative-photochemical response (that is, through absorption in the Hartley–Huggins bands of ozone) to small fluctuations in solar ultraviolet emission Variation in the absorption of reflected light from below in the Chappuis band of O_3 in the visible was, however, a feasible cause of the oscillation, and semi-annual (6 month) variations of cloudiness in the tropics have been suggested as a mechanism To explain a biennial (24 month) oscillation, one has to invoke a mechanism of sub-harmonic response which Staley[8] questions in regard to zonal momentum in the equatorial stratosphere In any case, as Staley points out, this would yield integral multiples of semi-annual or, in the extratropical region, annual forcing periods Subharmonic response would therefore fail to explain a period of about 26 months (A value of 26 2 months has been calculated from monthly means of zonal velocity based on 120 months of records at Balboa, at 9° S (ref 9))

We can show, however, that variations in solar emission associated with the double (22 yr) sunspot cycle[11] provide a possible mechanism by which the frequency of a biennial cycle can be shifted Assuming a sinusoidal carrier wave of orbital frequency $\nu_0 = \frac{1}{2}$ yr^{-1} with angular modulation by a single wave with frequency $\nu_M = 1/22$ yr^{-1}, one obtains principal side-band frequencies of $\nu_0 \pm \nu_M$, the corresponding periods being 22 0 and 26 4 months It is important to point out that angular modulation is a feasible mechanism whereas amplitude modulation yielding similar side bands would require additional energy presumably not available, for the oscillation We are indebted to Mr R R McGregor who drew our attention to this distinction

At this stage no plausible mechanism can be suggested whereby only the lower side band with an approximately 26 month period is observed, nor can we explain how the amplitude of the quasi-biennial oscillation varied with the single, 11 yr solar cycle But it is noteworthy that low-amplitude wind cycles with a 13 month period which have been detected in good data from the lower tropical stratosphere[10] can be interpreted in terms of modulation by this cycle, of a weak annual wave present in the tropical belt

Longitudinal Spread of pc 1 Micropulsations in the Magnetosphere

One of the important problems in the field of pc 1 micropulsation (pearl) research is to determine what portion of the magnetosphere is involved in the propagation of an individual structured pc 1 event. It is generally recognized[1] that these micropulsations propagate back and forth in a dispersive medium[2,3] between conjugate hemispheres guided by the Earth's magnetic field, but it is not known whether the waves are constrained to propagate along a single field line or whether they can spread out along an appreciable portion of a magnetic shell Because energy is transferred back and forth between trapped particles and ultra-low frequency (ULF) waves in the cyclotron resonance interaction[4], and because trapped particles undergo longitudinal drift, it is reasonable to assume that a structured pc 1 micropulsation may spread out along a magnetic shell even if it started on a particular field line Dispersion measurements[5–8] which have been used to locate the latitude where the field lines or shells intercept the surface of the Earth cannot be used to determine longitude, and hence one must resort to interstation comparison of data

Unfortunately, measurements of differences in polarization and of the arrival time of the same event at spaced stations are not sufficiently accurate to allow an unambiguous measurement of the longitude or spread in longitude of the magnetospheric portion of the path Comparison of the signal strength or occurrence rates at different stations may also be impossible because the final portion of the propagation path involves an ionospheric duct with unknown attenuation parameters

Fig 1 illustrates the type of interaction that may be present at the interface between the magnetosphere and ionosphere In the reflexion region, part of the incident wave must be reflected back along the field line and part must enter the ionospheric waveguide and be ducted horizontally in all directions at the broad minimum of phase velocity located between 300 and 700 km[9,10] Both

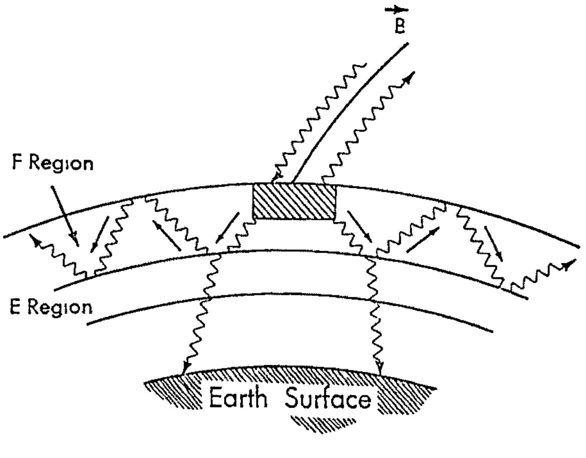

Fig 1 Possible ray paths of a structured pc 1 micropulsation The wavy lines represent the direction of propagation of the incident reflected and ducted waves as well as those which leak out of the *F*-region duct Mode conversion takes place in the cross-hatched area

the incident and reflected waves that are guided must be left-hand polarized whereas the unguided or ducted wave cannot have left-hand polarization Because waves are detected at the surface of the Earth, the waveguide must be leaky at the lower boundary and perhaps also at the upper boundary The spectral energy density of the received signal may be modified drastically during the short passage through the lower F and E region after leaking out of the duct because attenuation is orders of magnitude larger at these lower altitudes[9,10]

Some of the effects of this attenuation can be demonstrated by noting that stations located near 65° geomagnetic latitude rarely detect structured pc 1 at night[11], even though mid-latitude stations[8] detect many events at night which propagate on field lines or shells entering the duct at about 65° Because of this strong local absorption, it is difficult to determine the longitudinal extent of the magnetospheric path from interstation comparison of signal strengths and occurrence rates of pc 1 events

Further progress can, however, be made towards the solution of the longitude problem because of recent advances[12] in the interpretation of the pi 1 events known as "irregular pulsations of diminishing period" (IPDP)[13] These events usually last about an hour and consist of broad-band noise gradually increasing in frequency with structured elements frequently superimposed These structured elements arrive simultaneously in conjugate hemispheres and do not have a simple repetitive pattern[14] It has been shown[12,14] that these elements are guided along the magnetic field lines after having been initiated out in the magnetosphere near the equator Structured pc 1 and structured pi 1 events have the same frequency range, so that the effects of the ionosphere on these two different classes of guided micropulsations should be very similar

The results of the dispersion analysis of a large IPDP data sample[12] show that the structured elements propagate along field lines with equatorial geocentric distances between 7 and 13 Earth radii The diurnal variation of occurrence[1,12,15] and the rising frequency of IPDPs show that the event is characterized by a motion of some disturbance region being swept in and approaching the Earth by crossing field lines in the late evening hours

An interstation comparison of data presented in Fig 2 shows that the rate of detection of IPDP events at Seattle is approximately the same as that at College and is strongly associated with local magnetic disturbances as indicated by comparison with the Victoria K-index The College data were taken from the *High-Latitude Geophysical Data*[16] series without regard to emission frequency, and the Seattle data were scaled from original records in the same fashion Upper frequency limits of approximately 1 Hz are common at Seattle, whereas the IPDPs detected at College rarely exceed 0 5 Hz[15] Because all these emissions propagate on field lines which enter the ionosphere at higher latitudes than College[12], the loss of high frequency activity at College should not be caused by F-region duct attenuation but more likely by attenuation at lower altitudes after leaking out of the bottom edge of the duct Furthermore, the fact that the Seattle rate is essentially the same as the College rate, as shown in Fig 2, indicates that only a very small attenuation is incurred by the passage of the waves through an additional 1,500 km path in the F-region duct

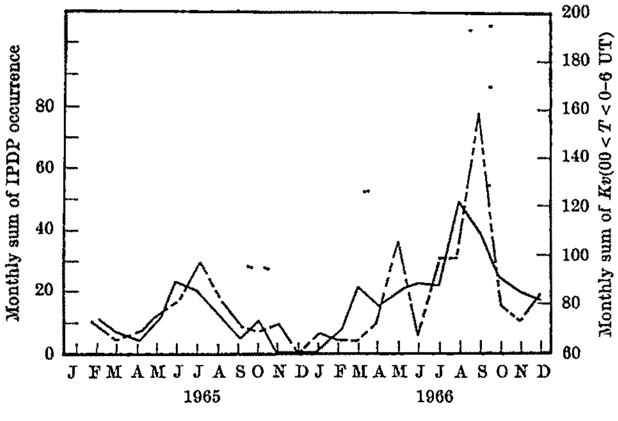

Fig 2 The variation of monthly occurrence of IPDP events for 1965 and 1966 The dashed line represents Seattle data and the solid line is for College data The dotted line forms a histogram showing the variation of the monthly sum of the local magnetic index Kv for Victoria, B C , during the hours (0–6 UT) , $\Sigma[Kv(0\text{–}3\ \text{UT} + Kv(3\text{–}6\ \text{UT})]$

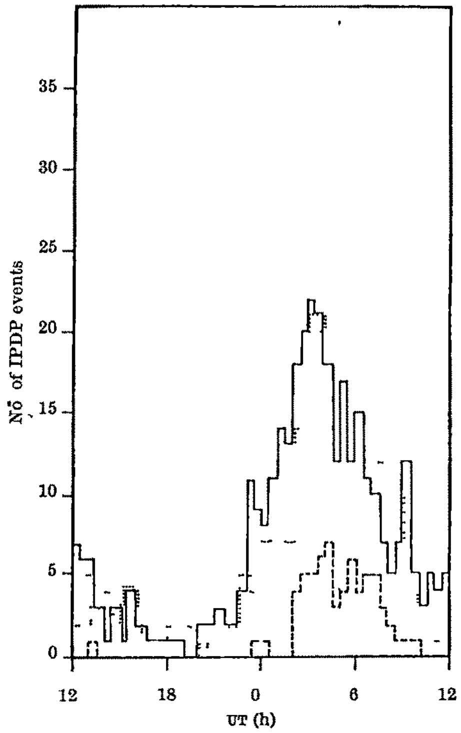

Fig 3 Three superimposed histograms showing the diurnal variation of occurrence of IPDP events from February 1965 to December 1966 The dotted histogram shows the diurnal variation of all IPDP events observed at Seattle, the solid one is for all IPDP events observed at College, and the dashed curve shows the diurnal variation of all IPDP events detected simultaneously at both sites

Similar occurrence rates can exist for these two stations if they always see the same event or if they merely see different events with the same probability Fig 3 is a plot of the diurnal variation of occurrence of all IPDP events detected either at Seattle or at College or simultaneously at both sites It is clear that the two stations do not normally see the same event even though they are separated by only 2 h in longitude An explanation that seems reasonable for the good north–south propagation of micropulsations (similar IPDP occurrence rates at Seattle and College) and the poor east–west propagation (low rate of simultaneous IPDP events at Seattle and College) is anisotropic coupling into the F region at the reflexion point shown schematically in Fig 1 Anisotropic coupling into the duct is more likely than anisotropic propagation after the wave is in the duct because of the peculiar boundary conditions that must be considered at the magnetosphere–ionosphere interface

On the other hand, there are many observations[1,17] of the detection of identical structured pc 1 events at stations widely separated in longitude A possible explanation for these observations is that a structured pc 1 event can have an appreciable spread in longitude along a shell in the magnetosphere rather than be constrained to propagate along a flux tube that is very restricted in longitude

Heating of the Upper Atmosphere during Geomagnetic Disturbances

During geomagnetic disturbances the upper atmosphere may be heated[1] either by injected charged particles and electrojets[2] or by magnetohydrodynamic waves and plasma oscillations[3] Early studies of the heating were based on some peculiarities of auroras at large heights[2] The detection of the increase of artificial satellite drag during geomagnetic disturbances[4-6] led to more widely accepted data on the phenomenon

Investigations of ordinary auroras by an interferometer method[7] show that within an error of ± 5 per cent the temperature of the upper atmosphere does not differ from that given in the 1965 Cospar International Reference Atmosphere for undisturbed conditions[8] This is the case even during auroras of the IV IBC type during which an energy of up to 600 ergs cm^{-2} s^{-1} can be introduced[9] About 10 per cent of this energy inevitably turns into heat Nevertheless, there are no observations showing considerable heating Before these investigations it was assumed[10] that during auroras at low heights a considerable cooling of the upper atmosphere may take place due to emissions by vibrationally excited NO and NO$^+$ molecules Such molecules can be easily formed not only at a high temperature but also as a result of different atomic exchange reactions Such reactions can develop most effectively during vibrational excitation of O$_2$ and N$_2$ It was supposed that the vibrational excitation of N$_2$ is possible during collisions with electrons[11] This process seems to be confirmed by the fact that during geomagnetic disturbances at middle latitudes the electron temperature in the ionosphere decreases[12] After the great geomagnetic storm on February 11, 1958, a decrease of ordinary daytime radio wave absorption in the D layer was observed[13] This can be interpreted as a result of the accumulation of very large amounts of NO in the upper atmosphere, perhaps exceeding 10^{17} NO cm^{-2}. In such circumstances, hydrogen Lyman α emission, penetrating into the D layer and ionizing NO there, will be considerably weakened, and will not be able to produce an ionized layer ensuring considerable absorption of radio waves Truttse (unpublished work) has observed that the published material of the IGY and the IQSY[14] contains indications of a considerable increase of the continuum of the night sky emission at middle latitudes during large geomagnetic storms This continuum is a result of the appearance of considerable NO concentrations[15,16] in the upper atmosphere It should also be recalled that in the spectrum of the aurora on February 11, 1958, two unidentified emissions at 3780 Å and 3812 Å were found[17] which are near to the components of the most intense 0–11 band of the β-system of NO (ref 18) NO and NO$^+$ molecules can emit about 3×10^{-13} ergs in 0 1 s and nearly restore their vibrational excitation during each collision with surrounding atoms and molecules[10] Thus if the result of interferometric investigations of the temperature during auroras is reliable, there are serious grounds for believing that the heating of the upper atmosphere at low heights (below 200 km) because of the injection of charged particles and electrojets cannot be important.

During large geomagnetic storms, however, the metastable atomic oxygen emission at 6300 Å (refs 19 and 20) which appears above 300 km is the main and predominant auroral emission Even in the mid-latitude region its diffuse fields have enormous extents and intensity The Doppler contour of this emission is very wide This indicates that even temperatures averaged over several hours reach 3,500° K (ref 21) Thus instantaneous temperatures can be much higher At the most intense spots during the aurora on February 11, 1958, the emission at 6300 Å reached 10^8 R, which corresponded to an energy flow amounting to 300 ergs cm^{-2} s^{-1} The intensity of this emission exceeded by four orders of magnitude the intensity of the green emission of atomic oxygen at 5577 Å, while the excitation potentials amount to 1 96 eV for the former and 4 17 eV for the latter, that is, they do not differ considerably Neither energetic, nor low-energy electrons nor hot electron gas with a Maxwellian energy distribution can be a reason for the excitation of red emission at 6300 Å In high-latitude regions during the injection of low-energy protons, which do not penetrate deeply into the atmosphere, the intensity of the emission at 6300 Å increases considerably[22]. But on February 11, 1958, hydrogen emission in high-latitude regions was not intensive and at middle latitudes did not exceed the observability threshold at all Thus the heating of the upper atmosphere by some plasma oscillations or magnetohydrodynamic waves remains at present the only probable reason for the appearance of red atomic oxygen emission at 6300 Å

The top of the upper atmosphere should be heated most intensively The boundary of the heated region will be lowered to levels at which the removal of injected heat outside the atmosphere will become possible The greater the injected energy, the lower the boundary of the high-temperature region The removal of the heat downward, however, as a result of thermal conductivity, is insignificant even during very great heating despite a large surface which removes heat and which is secured by a rapid levelling of the temperature in the top of the upper atmosphere

In these circumstances, the most probable processes are collisions and the atomic exchange reaction NO($^2\Pi$) + O(^{3}P)→NO($^2\Pi$) + O(^{1}D), during which the Wiegner rule is observed At high temperatures when the average energy of atoms and molecules approaches 2 eV, the rate of this reaction can amount to 10^{-10} cm^3 s^{-1} In such circumstances, most oxygen atoms will be in the ^{1}D state Thus at about 10^9 O cm^{-3} it is necessary to have about 10^{15} NO cm^{-3} for an emission at 6300 Å at 10^8 R (the maximum intensity observed) At a lower temperature but with an equal number of collisions these NO molecules can be excited and emit infrared photons with energies of about 0 2 eV The total energy in this region of the spectrum, however, will be an order of magnitude lower than in the red emission at 6300 Å the photons of which have energies of 1 96 eV At the same time the afore-mentioned NO molecules will take part in the creation of the continuum in the reaction $NO+O \rightarrow NO_2+\text{continuum}$[15] This reaction has a rate[16] of about 10^{-16} cm^3 s^{-1}, giving a continuum of 10^2 in a very wide region of the spectrum Such additional emission cannot be observed against the general background of the ordinary continuum Thus the increase in the continuum may only be due to the accumulation of large quantities of NO in lower parts of the atmosphere with a larger atomic oxygen concentration Large amounts of NO will, however, considerably cool the atmosphere As a result of this, the temperature at low heights will not increase essentially, because the downward flow of heat from strongly heated parts of the atmosphere, where emission at 6300 Å is emitted, is considerably weakened

The increase of artificial satellite drag during geomagnetic disturbances was interpreted in terms of heating of the upper atmosphere during which the height distribution of heat inflows corresponded to that typical of daytime ordinary, undisturbed conditions Indirect measurements of the increments in the exospheric temperature ΔT obtained from the value of the drag were not great, being about 1° K per a_p unit Direct measurements of such temperatures have not yet been accomplished Jacchia[23] has noted that the maximal drags and ΔT take place when the perigee of a satellite is situated at a height of about 650 km Lower and higher perigees correspond to smaller drags and ΔT. A higher location of the main source of heating does not contradict the relative distribution of drag with height described by Jacchia

The actual data available at present do not permit us to establish all the details of the heating process Truttse (unpublished work) has shown that the drag and the logarithm of the intensity of emission at 6300 Å (ref 24) are in phase and proportional to D_{st} On one hand, this dependency can be interpreted as evidence of a sharp non-linear increase of the heating agent with an increase of D_{st} On the other hand, it can be regarded as an indication of a sharp conversion from vibrational excitation of NO molecules and their quenching by infrared photons to the generation of emission photons at 6300 Å in the atomic exchange reaction because of the increase in the temperature In the latter case, the relation between D_{st} and the total energy in the NO infrared emission and the atomic oxygen emission at 6300 Å will not be so non-linear and perhaps will even be linear The choice between these two alternatives can only be made on the basis of simultaneous investigation of these emissions

Twenty-seven day and semi-annual variations of artificial satellite drag can also be associated with the heating of the upper atmosphere by plasma oscillations or magnetohydrodynamic waves which accompany geomagnetic disturbances and auroras The latter are characterized by remarkably similar synphase variations Variations of the upper atmospheric density with the time of day and with solar activity are well described by the existing models of the atmosphere, in which only variation of the solar electromagnetic radiation is taken into account It is very likely, however, that with further, more detailed determination of the heating processes a small contribution from magnetohydrodynamic and plasma wave absorption will be detected This should be taken into account despite the fact that solar hard ultraviolet radiation, absorbed in the atmosphere, is reliably known The problem is that the process of the transformation of energy into heat and the removal of this heat outside the atmosphere has not yet been explored with sufficient comprehensiveness

Age of the Upper Boulder Clay Glaciation in the Midlands

THE radiocarbon dating of 30–36,000 yr provided by Shotton[1] for peaty samples obtained from gravels occurring beneath the Upper Boulder Clay of the Four Ashes area [*SJ*9208], situated about 5 miles north of Wolverhampton, is probably the most important advance in absolute Pleistocene chronology yet achieved by the method of age determination in the English Midlands It has proved that the Upper Boulder Clay is a viable time-stratigraphic unit within the Shropshire–Cheshire Basin[2,3] and disproved the hypothesis that the maximum limit of advance of the ice-sheet which laid down the Upper Boulder Clay in north Cheshire reached only as far as the Wrexham–Bar Hill morainic suite situated in the centre of the Shropshire–Cheshire Basin[4] By inference this dating must support the view that the complex Wrexham–Bar Hill end-moraine is of pre-Upper Boulder Clay (Middle Sands) age[2,3] and therefore cannot be correlated with the Brandenberg and Lesnow moraines as suggested by Boulton and Worsley[4] Furthermore, it also shows that the variations in carbonate leaching properties discovered by Boulton and Worsley in the Upper Boulder Clay to the north and south of this morainic suite are not necessarily indicative of age differences between these deposits as suggested by them[4]

The sequence of glacial deposits within the Shropshire–Cheshire Basin[2,3] comprises an Upper Boulder Clay (now shown to be of Wurm II age), Middle Sands (of radiocarbon age-determinations ranging from 28,000[4] to 57,000[5] yr old) and Lower Boulder Clay (by inference probably of Würm I age) The melt-phase of each glaciation produced separate and distinct glacial lake features within the Shropshire–Cheshire Basin[2] and from the Four Ashes age determination of 30–36,000 yr we must conclude that the Main Terrace of the River Severn (dated downstream from Ironbridge at 42,000 yr (ref. 6) correlates through the Ironbridge Gorge with a glacial lake-stage formed during the melt-phase of the Lower Boulder Clay glaciation (products of which probably include the Middle Sands Wrexham–Bar Hill morainic suite) rather than with the long accepted correlation with glacial Lake Lapworth[7], for the uppermost Lake Lapworth features are cut into and obviously postdate the Upper Boulder Clay of the type Shrewsbury (sheet 153) area[2,3,7]

While this new radiocarbon dating has helped to standardize the chronology of the Shropshire–Cheshire Basin, it accentuates the need for further such absolute chronology to be obtained in the critical Wolverhampton–Birmingham area A glance at the one-inch geological drift maps 153, 154 and 168 shows that the now-proved Wurm II Upper Boulder Clay of the Four Ashes area occurs on the north-western margin of an almost continuous till-sheet which extends eastwards over the Cannock Coalfield and south-eastwards into the West Bromwich and Edgbaston area of Birmingham The so-called "Wolverhampton Line"[1] is merely an approximate limit of large "Irish Sea" erratics in the Upper Boulder Clay and as such is not absolute evidence of the maximum limit reached by ice-sheets in the Wurm II period of glaciation The boulder clay to the south of the River Tame south of Walsall is chiefly composed of locally derived Coal Measures material in which "Irish Sea" erratics are occasionally found It is notable that Kelly has recorded "Irish Sea" erratics in the Upper Glacial deposits of the North Birmingham area[8] and it would seem at least possible that the uppermost boulder clay (Edgbaston Till) of his complex succession hereabouts may correlate with the Wurm II boulder clays of the Four Ashes area

Koyna Earthquake

THE Koyna earthquake of December 11, 1967, killed about 200 people and injured a few thousand The epicentre was within 5 km of the Koyna Dam (17° 23′ N , 73° 45′ E) A magnitude of the order of 7 5 on the Richter scale has been reported by the Indian Meteorological Department and the Central Water and Power Research Station The depth of focus of the earthquake has been estimated at about 30 km The earthquake was felt over distances up to 700 km from the epicentre Geologists, basing their opinion on this information, have suggested that the earthquake resulted from movements along a fault, possibly a satellite of the principal fault along the Malabar coast, and that it may be an isolated event unconnected with the reservoir and the earlier seismic activity

Koyna Dam and the Shivaji Sagar Lake formed by it are situated in the western part of the peninsular shield which is covered by the Deccan lava flows commonly known as Deccan Traps The dam was constructed on the Koyna river which originates in the Mahabaleshwar region and runs practically north–south up to Helwak, a point which is very close to the epicentre and where the river turns sharply to the east

The peninsular shield is one of the nearly non-seismic stable central shields of the continents Isolated shocks of low magnitude have been reported on the western and eastern ghats The Koyna reservoir was impounded in 1962 and reports of Earth tremors near the site of the dam began to be prevalent soon afterwards The frequency of tremors increased considerably from mid-1963 From September 1964 to March 1966 sixty-one tremors were recorded and their epicentres were determined using data from a network of four closely spaced seismological observatories at Mahabaleshwar, Satara, Govalkot and Koyna Nagar (Fig 1) During 1967, five tremors were recorded by a few other seismological observatories as well as the four situated in the neighbourhood of Koyna Dam Studies of these tremors showed that the epicentres of most of these were located within a small radius around the dam site The foci of these tremors were located at a depth of about 4 km, and they were attributed to crustal adjustments within the Deccan lava flows[1] Before the earthquake of December 11, there was a shock on September 13, 1967, in this region which was widely felt and caused minor local damage This was the first earthquake in this area to arouse public anxiety

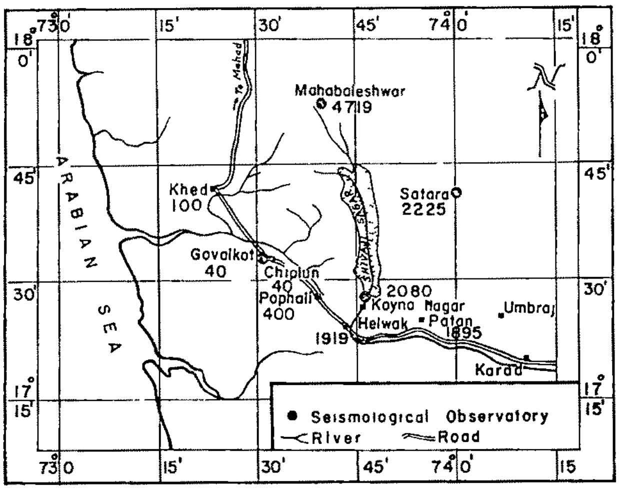

Fig. 1 Koyna Nagar and its surroundings

Field investigations carried out by us after the Koyna earthquake of December 11 showed very localized damage Koyna Nagar and some areas to the south are the most affected, where the intensity hardly exceeds 8 on the MM scale Poorly constructed brick and mud houses have withstood this earthquake at small distances of 8–10 km Field studies indicate a much smaller magnitude than 7 5 and a depth of focus shallower than 30 km The large distances of 700 km over which the earthquake was felt may be a consequence of the good transmission of energy in the shield area

We have obtained seismograms from Adelaide, Athens, Anpu, Kongsberg, Valentia and Kirkenes, where the seismological observatories are equipped with WWSSS. The surface wave magnitude has been determined for the Koyna earthquake from these seismograms and an average value of 6 2 is obtained (Table 1) The Uppsala observatory has reported a magnitude of 6 25 for this earthquake and the same value has been assigned by Adams (personal communication) It is therefore established that the magnitude of this earthquake is of the order of 6 2

Table 1

Recording station	Surface wave magnitude
Adelaide, Australia	6 2
Anpu, Taiwan	6 3
Athens, Greece	5 9
Kongsberg, Norway	6 3
Kirkenes, Norway	6 3
Valentia, Ireland	6 3

Seismic activity has been reported to be associated with the filling of the Boulder Dam by Carder[2] where several hundred small earthquakes were felt and several thousands were recorded by seismographs in the vicinity of the Boulder Dam reservoir after it was filled in 1935 These earthquakes were of low magnitude and did not cause any damage Adams (personal communication) has found a three-fold increase in seismic activity at Mangla Dam in Pakistan following its filling

Evans[3,4] has put forward the classic example of Rocky Mountain Arsenal near Denver where a deep well was used for disposal of waste fluids Otherwise a non-seismic area, Denver experienced about 700 tremors during 3 5 yr The frequency of these tremors was found to be high during the months of high injection and vice versa The Pre-Cambrian rocks of the Arsenal reservoir are highly fractured and rest on steep slopes The increase of fluid pressure within the reservoir decreases the frictional resistance along the fracture planes and the movement occurs The elastic wave energy thus released is recorded as earthquakes The largest recorded magnitude in this area is 4 8 on the Richter scale

Association of the enhanced seismic activity in the Koyna region with the impounding of the dam is established beyond doubt Guha *et al* [1] have shown an increase in the seismic energy release in this area with the increase of the reservoir level with a certain time lag The highest recorded magnitude for tremors in this region until March 1966 was of the order of 4 00 The earthquake of September 13 had a magnitude of the order of 5 0 and the earthquake of December 11 of the order of 6 0 These events all seem to be connected

The exact mechanism of the seismic activity associated with the loading of the reservoir is not known Without doubt the hydrostatic pressure of 50 lb /in ^{2} exerted by the Koyna reservoir could not be directly responsible for an earthquake of magnitude 6 0

There is the possibility that the Koyna river itself flows along a fault and that water from Shivaji Sagar Lake percolating through great depths could have created certain imbalances in hydrostatic pressures resulting in slippage along fracture planes This mechanism itself could also act as a triggering agency for some sort of chain reaction at depths of 5 to 10 or 15 km Detailed geological and geophysical investigations in this region and studies of the seismological records of the earthquake, its fore-shocks and after-shocks are essential if the cause of this earthquake in this part of the stable peninsula is to be understood

Chemical Composition of Dew and Dry Fallout in Jerusalem, Israel

THIS report describes the first results of an analysis of the chemical composition of dew collected in Jerusalem, Israel, during the dry summer season of 1967 The data are compared with analyses of precipitation and dry fallout carried out during previous years (unpublished results of Yaalon and Jacobs), which were made in an attempt to evaluate the contribution of airborne salts to the circulation of soluble salts[1,2]

Thirty-five samples of dew were collected during the rainless months July to October 1967 In twenty-one of these the amount exceeded 150 ml (equivalent to more than 0 15 mm of dew per night), which sufficed for a complete chemical analysis (including Na, K, Ca, Mg, Cl SO_4, HCO_3, *p*H and conductivity) according to the methods currently used by this laboratory for rain water analyses Only partial analyses of the remaining smaller samples were made.

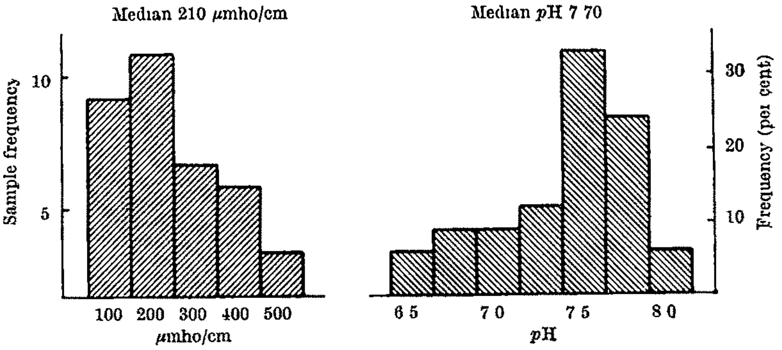

Fig 1 Frequency distribution of conductivity and *p*H values in 33 samples of dew, Jerusalem, summer 1967 Minimum and maximum values of conductivity are 100 and 500 μmhos cm^{-1} (25° C), the *p*H range is 6 55 to 8 10

Dry fallout during the rainy winter season of 1962–63 was collected by washing a large polyethylene funnel (area 700 cm^2) and the bottle which served as rain collector with exactly 1 1 of double distilled water

The concentration of soluble salts found in the dew is usually within the range of concentrations found previously in the precipitation (unpublished work of Yaalon and Jacobs) There is a clear inverse relationship between the amount of dew and salt concentration The average chloride concentration in dew on days with < 0 1 mm of dew is three times as large as in the rest of the samples In part the effect may be because of some evaporation of the dew from the glass collecting plate Because of occasional high concentrations the frequency distributions of the ionic concentrations are all positively skewed and

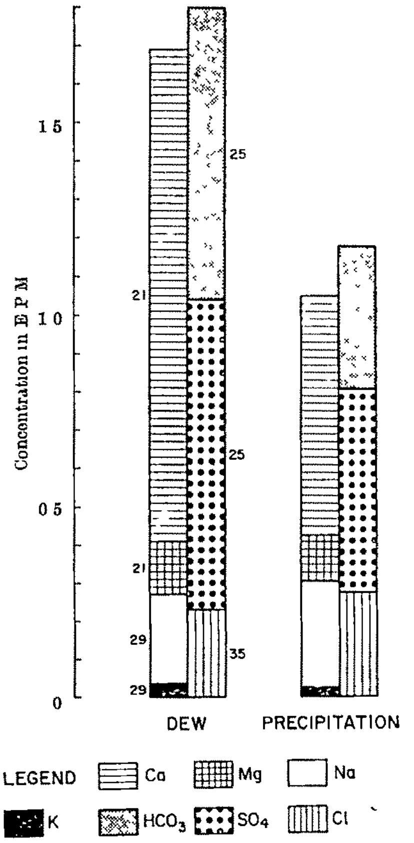

Fig 2 Average chemical composition of dew and bulk precipitation in Jerusalem The number of analyses available for the calculation of the median values of dew are indicated in the graph Values of bulk precipitation are the means of rainfall years 1960/61–1962/63

tend to be log-normal Medians rather than means were therefore calculated The frequency distributions of conductivity and pH values are shown in Fig 1, the medians being 210 μmhos cm^{-1} and pH 7 7, respectively Median values for all the analysed ions are plotted in Fig 2, and compared with the weighted mean concentrations of precipitation in Jerusalem The inequality between the sum of cations and anions is explained principally by the disregard of ammonia in the analyses[3] The median total amount of dissolved solids (calculated) in the dew is 120 mg l^{-1}, more than that in the precipitation Fog water has also recently been found to contain greater concentrations than rainfall[4]

From Fig 2 it seems that dew is richer than precipitation in Ca, HCO_3 and SO_4. This enrichment becomes still more evident from the ternary plots showing the relative amounts of cations and anions (Fig 3) In spite of the fairly large variations in the concentration of the salts, their relative proportions in the dew vary remarkably little In the precipitation the variations are usually much larger (unpublished work of Yaalon and Jacobs, and ref 6) The dominance of Ca and HCO_3 is easily explained as being due to calcareous dust from rocks and buildings in the Jerusalem environment[5] Possibly some of the fine calcareous dust particles act as condensation nuclei for the dew and are dissolved in the process Sulphate is doubtless derived from sulphur dioxide in the air It seems to dissolve the carbonate minerals in the dusty air, thereby producing some calcium sulphate

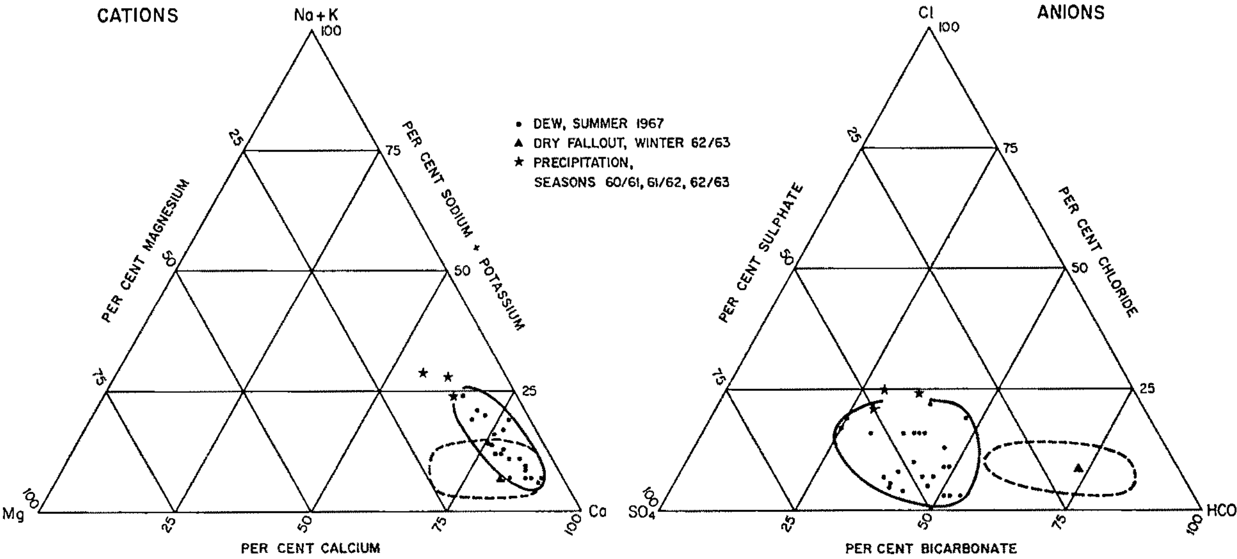

Fig 3 Diagram showing general chemical character of dew, bulk precipitation and dry fallout in Jerusalem, Israel Sum of equivalent reacting values for cations and anions equals 100 per cent

Both the average concentration and the relative ionic proportions of Cl, Na, K and Mg in dew are remarkably similar to those in the precipitation This seems to suggest the same maritime source for these salts Evidently the moisture which condenses as dew scavenges salts and aerosols from the air just like bulk precipitation Whitehead and Feth[6] reported that in California bulk precipitation, which includes dry fallout deposited on the collector between rains, is 4 to 10 times higher in mineral concentration than rainwater

Sodium and potassium have been combined in the ternary diagrams The low Na/K ratio, which in all of the twenty-eight analyses was less than 10 (median 6 5), is, however, noteworthy The Ca/Mg in the dew, varying from 7 to 25 (median 10), is relatively high, reflecting the effect of dissolution of $CaCO_3$ dust The influence of calcareous dust is even more evident in the composition of dry fallout (Fig 3) In the dry fallout (eighteen samples), the relative proportions of all constituents except Ca and HCO_3 are similar to those in the precipitation

Only very approximate calculations can be made of the total contribution of dew and dry fallout to total salt precipitation. Measurements of dew in Israel[7,8] indicate that in Jerusalem there are about 150 dew nights per year, depositing something like 0 15 mm per dew night or a total of about 25 mm per year, with maximum frequency and quantities in September Although the amount of dew depends greatly on the nature of the surface on which it collects, the present measurements generally confirm these averages Dew would thus contribute an amount of Cl and the other oceanographic salts equivalent to 25 mm of winter precipitation Dry fallout contributes several times more than this, principally because it is not confined to the few night hours of dew condensation The total amount of dry fallout in summer cannot yet be estimated because of inadequate data In the rainy winter season it is included with the precipitation Estimates from other countries that dry fallout contributes more than rainfall[6,9] may well be correct for Jerusalem

In conclusion, these data seem to suggest that dew condensation represents rather well the chemical composition and relative proportions of the oceanogenic part in aerosols and dry fallout It may be worthwhile to determine the relative concentrations of these and other salts at other places also, and to determine the concentration gradients with distance from the sea

We thank Mrs T Braun for carrying out the chemical analyses and Mr A Katz for collecting the dry fallout samples

PHYSICS

Self-trapping of Radiation Produced Electrons

THE problem treated here is the trapping of free electrons produced by ionizing radiation in dielectric systems Detailed theoretical descriptions of the equilibrium properties of the solvated electron are available[1-3], but its formation is still under discussion Electrons are formed and thermalized in the coulomb field of the positive ions, but not fully recaptured by the ions Magee[4] considered the auto-ionization of the H_3O radicals as a possible secondary source of electrons, Freeman[5-7] assumed the electrons to be trapped in the defect sites of the medium at the instant of thermalization, while we thought[8,9] that in polar dielectrics the escape of the electrons from the ions can be a free-energy decreasing, and therefore spontaneous, process In our approach, the electrons which escape are treated as quasi-free, and the question of the kinetics and mechanism of electron trapping arises Diffusion kinetic calculations on the radiolysis of water[10,11] suggest very high initial hydrated electron densities, which require fast trapping processes

Our electron escape theory used a continuous dielectric medium to which the notion of any defect site is not applicable This theory has already been proved experimentally to some extent[12] Thus in keeping with Platzman's original conception[13], and with the picture given recently by Boag[14], we shall discuss the stabilization of the electron in the medium as a self-trapping process, that is, as the formation of an energy well in the medium under the influence of the electric field of the electron The question to be answered is how much time is needed for a free electron in a dielectric substance to form an energy well of suitable depth ?

An electric charge of density ρ induces in a dipolar medium some polarization of its environment The extent of this process can be characterized by a polarization charge density ρ^* In the case of equilibrium, $\rho_e^* = (1-\varepsilon_s^{-1})\rho$, where ε_s is the static dielectric constant of the substance (see appendix) This relationship is correct only as far as the absolute values are concerned, ρ^* and ρ being of opposite sign An electron becomes self-trapped if the polarization charge density is high enough to produce a strong positive field which is able to trap the electron The presence of solvated electrons in a system shows ρ_e^* to have met this requirement

An electron will become trapped at a place $\mathbf{r}$ and a time t, where the actual density of polarization charges equals or surpasses the equilibrium value, that is, where the following inequality holds

$$\rho^*(\mathbf{r},t) \geq (1-\varepsilon_s^{-1})\rho(\mathbf{r},t) \quad (1)$$

An inducing charge immediately influences non-polar dielectrics to form their polarization charges The polarization is much faster than the change in the field strength caused by the motion of a thermal electron Thus the condition of inequality (1) is met at the instant and site of thermalization, or not met at all Because it has been shown[9] that thermal free electrons occur with only a very low probability in non-polar systems, this point will not be discussed

Polar dielectrics need some time for the polarization charges to be formed For a large class of polar substances, including water, this formation can be described by the equation

$$\rho^*(\mathbf{r},t) = (1-\varepsilon_\infty^{-1})\,\rho(\mathbf{r},t) + \bar{\varepsilon}^{-1}\vartheta^{-1}\exp(-t/\vartheta)\int_0^t \rho(\mathbf{r},t')\exp(t'/\vartheta)\,dt',$$

$$\bar{\varepsilon}^{-1} = \varepsilon_\infty^{-1} - \varepsilon_s^{-1}, \quad \vartheta = \varepsilon_\infty\tau/\varepsilon_s \quad (2)$$

where ε_s and ε_∞ are the static and infrared dielectcir constants, respectively, and τ is the dielectric relaxation time (see appendix)

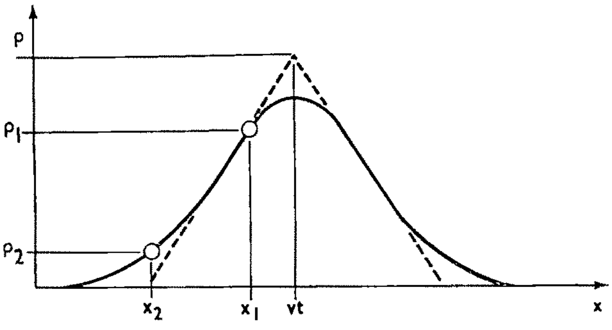

Fig 1 Schematic electron density distribution

The sluggishness of the polarization, reflected in equation (2), helps the electron to be trapped Thermal electrons spreading out over a number of water molecules can be characterized by some continuous charge density, which depends on space and time, and is qualitatively similar to the density distribution given in Fig 1 Let the electron move in the direction of the $+x$ axis The high charge density ρ_1 tends to induce a certain amount of polarization in the medium at x_1 The polarization charges form slowly and, although they continue to do so after ρ_1 has left site x_1, this process is far from complete by the time the low charge density ρ_2 reaches x_1 The polarization charges at x_1 are insufficient to trap the high density part of the electron, because their density is much lower than required by inequality (1) The polarization at x_1 as induced by ρ_1 might, however, trap the low density part of the electron, ρ_2 This is meaningful in statistical terms

This qualitative picture can be formulated by combining inequality (1) and equation (2) to give the expression

$$\rho(\mathbf{r},0) + \int_0^t [\partial\rho(\mathbf{r},t')/\partial t']\exp(t'/\vartheta)\,dt' \leq 0 \quad (3)$$

Inequality (3) defines for each moment t a volume $V(t)$ which contains all the points—that is, the space vectors $\mathbf{r}$, where this inequality is met.

The trapping probability $p(t)$ for the period of time $[0,t]$ is equal to the probability of finding the electron in the volume $V(t)$

$$p(t) = \int_{V(t)} \rho(\mathbf{r},t)\,dV \quad (4)$$

The quantum mechanical calculation of the time-dependent electron wave-function in a potential well formed by the electron itself is insoluble A very crude estimate can be made by describing the electron as a travelling wave packet of constant geometry; that is, the effect of elapsing time which tends to broaden the charge-distribution and the effect of the potential well being formed which tries to confine the electron are neglected If the electron moves with a constant velocity v in the $+x$ direction, the one-dimensional density function has the general form $\rho = \rho(x-vt)$, and inequality (3) assumes the form

$$\rho(x,0) - \vartheta v(\partial\rho/\partial x)[\exp(t/\vartheta) - 1] \leq 0 \quad (3')$$

The solvation probability is given as

$$p(t) = \int_{-\infty}^{x} \rho(x')\,dx' \quad (4')$$

Solvation takes place, according to equation (3′), only at those sites where $(\partial\rho/\partial x) > 0$, that is, along the ascending part of $\rho(x)$ Hence this model leads to a 50 per cent solvation as an upper limit.

A numerical guess can be made by using the "roof" dotted in Fig. 1 as a normalized electron density function This has the following analytical form

$$\rho(x-vt) = (-1)^\alpha(\sqrt{2}\lambda)^{-2}(x-vt) + (\sqrt{2}\lambda)^{-1}$$

$$\alpha = \begin{cases} 0 \text{ if } x-vt \leq 0 \\ 1 \text{ if } x-vt > 0 \end{cases} \quad (5)$$

whereas the continuous curve in Fig 1 is that of the Gaussian function $[(\lambda\sqrt{\pi})^{-1} \exp [(x-vt)/\lambda]^2$ According to equation (5), τ has a finite range and so a well defined period of time for the completion of trapping The de Broglie wavelength λ of an average thermal electron is 60 Å, and its average velocity $v = 1 \times 10^7$ cm s^{-1} Using these values and the dielectric characteristics of water[15] ($\varepsilon_s = 80\ 1$, $\varepsilon_\infty = 4\ 9$, $\tau = 1\ 01 \times 10^{-11}$ s), the self-trapping process takes about $t_m \approx 3 \times 10^{-13}$ s

If the travelling velocity of the polarization charges is known, the site of the self-trapping can be determined It is shown in the appendix that there is only a small difference between the velocity of the centre of the polarization charge cloud $\mathbf{v}^*$ and that of the centre of mass of the electron $\mathbf{v}$ Thus we simply compute with v and evaluate[13] the average distance travelled by the electron from the site of thermalization to the site of self-trapping as the geometrical mean of its maximum path length of vt_m and minimum displacement of $\sim 10^{-8}$ cm Here we get about 17 Å for the mean displacement This figure agrees with the radius of electron spurs used as parameters in diffusion kinetic calculations by Schwarz[10] and Kuppermann[11] This final result is almost independent of v

This agreement is thought to be somewhat fortuitous and cannot be considered as a heuristic proof of our treatment There are, however, semiquantitative results of the present calculation which we consider both valid and important

According to inequality (3), solvation can take place at those sites where the electron density decreases, that is, where $(\partial\rho/\partial t) < 0$ This proves our previous assumption[8,9] that the electrons of a spur or track which become solvated are those which are able to escape, moving outward from the positive ions and thus decreasing the density of the electron heap

Quasi-free electrons in a polar substance become self-trapped in much shorter periods than the dipolar relaxation time, self-trapping being about as fast as thermalization Thus thermalization and self-trapping take place almost simultaneously

Appendix Let us define ρ^* as the source of the polarization Using standard notation[16]

$$\rho^* = \mathrm{div}\,\mathbf{P} = \frac{1}{4\pi}\,\mathrm{div}\,(\mathbf{D}-\mathbf{E}) = \rho - \frac{1}{4\pi}\,\mathrm{div}\,\mathbf{E} \tag{6}$$

For a large class of polar substances **D** and **E** are interrelated by the differential equation[16]

$$\mathrm{d}\mathbf{E}/\mathrm{d}t + \mathbf{E}/\vartheta = \mathbf{D}/\varepsilon_\infty \tau + (1/\varepsilon_\infty)\mathrm{d}\mathbf{D}/\mathrm{d}t \tag{7}$$

By combining equations (6) and (7) one gets equation (2) In the case of equilibrium $\mathbf{D} = \varepsilon_s \mathbf{E}$ and, when this is inserted into equation (6), ρ_e^* is found

The centres of the electron cloud $\mathbf{r}_0$ and that of the polarization charge cloud $\mathbf{r}_0^*$ are defined as

$$\mathbf{r}_0 = \int_V \mathbf{r}\rho(\mathbf{r})\mathrm{d}V \quad \text{and} \quad \mathbf{r}_0^* = \int_V \mathbf{r}\rho^*(\mathbf{r})\mathrm{d}V \tag{8}$$

The corresponding velocities are

$$\mathbf{v} = \mathrm{d}\mathbf{r}_0/\mathrm{d}t \quad \text{and} \quad \mathbf{v}^* = \mathrm{d}\mathbf{r}_0^*/\mathrm{d}t \tag{9}$$

The combination of equations (6), (7) and (9) leads to the expression

$$\mathbf{v}^* = \frac{1-\varepsilon_\infty^{-1}}{1-\varepsilon_s^{-1}-\bar{\varepsilon}^{-1}\exp(-t/\vartheta)}\,\mathbf{v} + \frac{(1-\varepsilon_s^{-1})(\bar{\varepsilon}\vartheta)^{-1}\exp(-t/\vartheta)\int_0^t \mathbf{v}[\exp(t'/\vartheta)-1]\mathrm{d}t'}{[1-\varepsilon_s^{-1}-\bar{\varepsilon}^{-1}\exp(-t/\vartheta)]^2} \tag{10}$$

or, because the second term in equation (10) is never negative

$$\mathbf{v} \geq \mathbf{v}^* \geq [(1-\varepsilon_\infty^{-1})/(1-\varepsilon_s^{-1})]\mathbf{v} \tag{11}$$

The lower limit even for highly polar water is as high as 0 8 v Therefore the approximate identity

$$\mathbf{v} \approx \mathbf{v}^*$$

holds

I thank Dr M Ebert for his help during the preparation of the manuscript

Vibration Analysis by Stroboscopic Holography

This communication describes a method for vibration analysis in which fringes are directly related to the amplitude of the vibrating object. This is achieved by combining the frozen fringes technique with stroboscopy

Wavefront reconstruction interferometry is, by now, a well established technique, and some applications of this technique, sometimes referred to as the "frozen fringes" method, have been described[1,2] Powell and Stetson[3,4] have extended the method to vibrating objects

When a hologram is made in the normal way from a vibrating object[3,4], interference fringes are seen on reconstruction These fringes are uniquely related to the probability density function of the motion of the object and not to the particular motion Thus the fringe pattern is not directly related to any physical parameter which could be otherwise measured In any vibration analysis the position of vibration nodes is of primary interest This method does not give the direct answer

With a conventional optical arrangement a hologram of the object was recorded on the photographic plate The exposure time, however, was half that which would be required to produce a good hologram The object was then acoustically excited using a signal generator and a 6 W loudspeaker At the same time, the laser light was chopped in synchronization with the vibrating object by a slot in a disk driven by a synchronous motor coupled to the same signal generator The same photographic plate, retained in precisely the same position, was exposed again The exposure time was adjusted so that the final density (about 0 5 log units) gave a bright good-quality reconstruction The object, a "T" piece clamped by its central shorter leg to the loudspeaker frame, was vibrating at its first resonance frequency, about 226 Hz The chopper produced a light pulse of approximately 40 μs The phase was adjusted to "freeze" the motion at approximately maximum displacement—that is, at the position where the velocity is zero. Fig 1 shows stroboscopic fringes obtained by double exposure

The object was vibrating about the horizontal axis, parallel to the plane of Fig. 1, so all fringes should have been horizontal and parallel. Because of the vibration of the whole mounting of the loudspeaker, however, the recorded resultant motion was far more complicated than simple harmonic oscillation. This changed the shape of the fringes. The motion of the frame was detected, of course, by the presence of stroboscopic fringes on it. For comparison Fig. 2 shows Powell and Stetson fringes[3] of the same object under exactly the same excitation.

This stroboscopic method also allows the analysis of objects vibrating with larger amplitudes than the method of Powell and Stetson. This is shown in Figs. 1 and 2; the fringes in Fig. 2 have smaller spacing than in Fig. 1 for the same amplitude. Furthermore, stroboscopic holography can be used to obtain fringes at any amplitude less than the maximum. In this case the light pulse would have to be reduced as the velocity would have a finite, and possibly, large value. This, in turn, would require an increase of the exposure time. The exposure times used were moderately short. With the illuminating pulse occurring every ninth cycle and an 80 mW c.w. He–Ne laser the exposure time was between 2–4 min. The hologram produced measured approximately 10× 10 cm.

The interpretation of fringes obtained stroboscopically is far easier than of those of Powell and Stetson. The fringes here, as in the frozen fringe method, are directly related to displacement and therefore to the amplitude of the vibrating object. The interpretation of such fringes was discussed by Haines[2] and his conclusions are directly applicable. Here, as in all interferograms, the sign ambiguity of the amplitude exists. The sign must be predicted from experience.

With this method, as with those previously described[1-4], live fringes can be obtained. The hologram is first made from the non-vibrating object and replaced in exactly the same position as it occupied during the exposure. Then if the vibrating object is illuminated stroboscopically and viewed through the hologram the reconstructed image from the hologram will interfere directly with the light scattered from the object and live fringes will be seen.

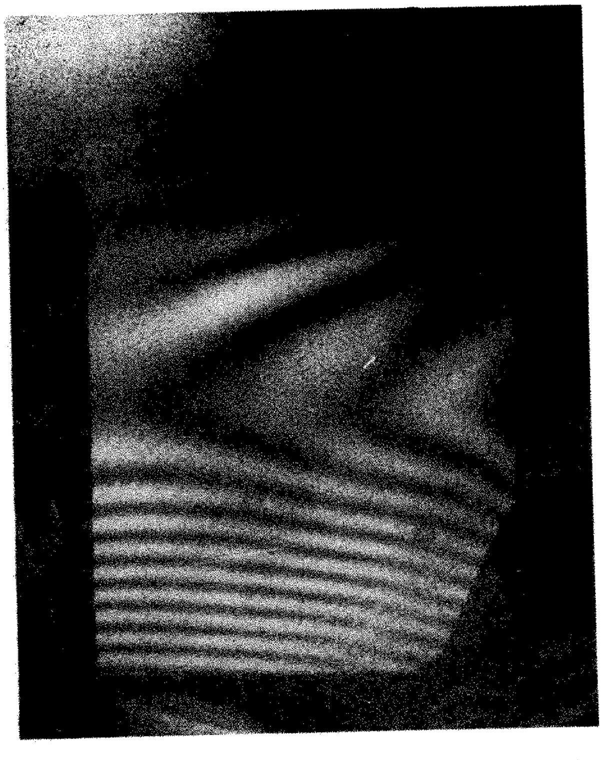

Fig. 1. Frozen fringes obtained stroboscopically from a vibrating object.

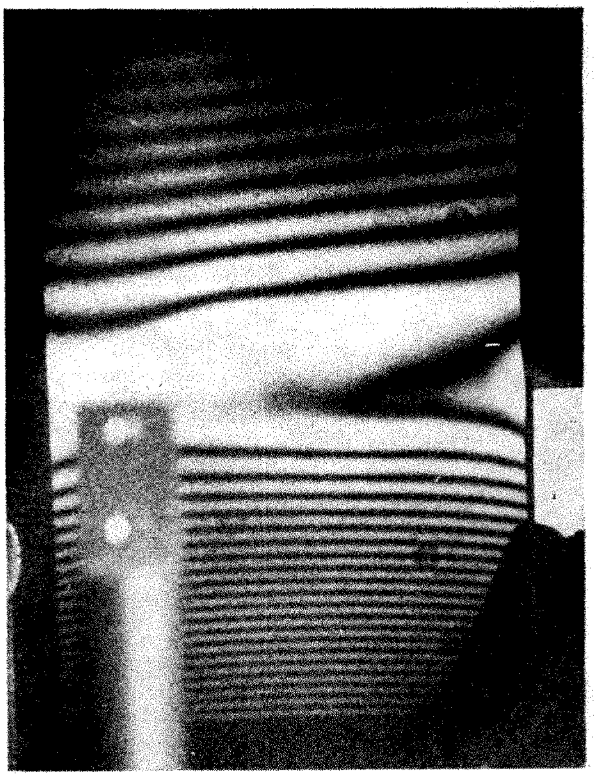

Fig. 2. Powell and Stetson fringes obtained with the same vibrating object. In the foreground a standard optical bench rod is seen.

Finally, if a Powell and Stetson hologram is made with stroboscopic instead of continuous illumination, the pulse width of the chopped light will determine the range of amplitude recorded on the hologram. Thus on reconstruction, the fringes will correspond to an object vibrating over a smaller amplitude range.

We thank J. Ackroyd, L. G. May and P. Atkins for useful discussions.

Measurement of the Diffusion Coefficient of Radium A

THE potential hazard in mines from the inhalation of the progeny of radon gas has become increasingly interesting in recent years. This hazard involves radon daughters in two forms: (*a*) attached to aerosol particles or condensation nuclei; and (*b*) unattached atoms or ions. The form of the unattached daughters is not fully known, but one of their important and basic characteristics is their diffusion coefficient. Of special interest is the diffusion coefficient of the first radon daughter, ^{218}Po, called radium A. This parameter is very important not only in describing atmospheric behaviour[1] but also in considering the biological hazard of inhaling unattached daughters[2].

Radon decays by alpha emission, with a half-life of 3·825 days, to form radium A with a recoil energy of

120 KeV. It is positively charged from the stripping of orbital electrons by the departing alpha particle or by the recoil motion. Its recoil range in air is about 50μ. How long it remains charged and into what chemical reactions it enters have not been demonstrated. It is possible that the radium A ion is quickly neutralized and forms polonium oxide.

On contact, radium A becomes attached to surfaces. Because it has a high diffusion coefficient, and because the most available surfaces are the surfaces of aerosol particles, radium A rapidly becomes attached to aerosol particles at a rate dependent on the aerosol concentration and on the diffusion coefficient. Similar effects occur with other unattached radon progeny, the most important being ^{214}Pb, called radium B, and ^{214}Bi, called radium C. Curie[3] observed that the attachment seemed to be affected by water vapour, but this effect has not been elucidated.

If unattached radium A is inhaled by a human, it deposits by diffusion on the walls of the respiratory tract. How much is deposited during breathing and where in the respiratory tract this deposition occurs depend on the diffusion coefficient of radium A. The diffusion coefficient of radium A is reported to be approximately 0·05 cm^2 s^{-1} (refs. 2 and 4). This is smaller than would be expected for a single uncharged atom (0·1 cm^2 s^{-1}), implying either a charged atom or a small cluster of atoms. The importance of water molecule interactions has not been clearly demonstrated. In this study, the diffusion coefficient of radium A was measured in two different conditions of humidity (described by the temperature of the dew point). An apparent effect of the humidity of the atmosphere on the diffusion coefficient was found.

The technique introduced by Townsend[5] was used to make these measurements. This technique consists of drawing the radon daughters through cylindrical tubes of various lengths and observing the penetration fractions. For these experiments glass tubes of small diameter were used. A filter was placed at the end of each of the tubes to collect the penetrating radon daughters, and these filters were counted for alpha activity. The air concentrations of the radon daughters were calculated by mathematical study of the decay of each sample[6]. To correct for the production of radon daughters during passage of the radon gas through the tubes, similar measurements were made with filters also at the entrances of the tubes and the small concentrations of radon daughters found with these prefiltered samples were subtracted from the corresponding unfiltered penetration concentrations.

Samples were taken from the centre of a 1,000 l. chamber through which clean air containing radon gas was continually flowing. The supply of air for the chamber was doubly filtered. The state of humidity depended on the meteorological conditions. The radon gas was generated by bubbling a small quantity of air through a dilute hydrochloric acid solution containing radium chloride. The arrangement was basically that described by Wilson[7]. Before entering the radium chloride solution, the air was filtered and passed through a conditioning bubbler for humidification. The radon-laden air was passed through an overflow and droplet trap and then through a soda lime trap. It was doubly filtered at the entrance to the chamber, where it was mixed with the clean air. Independent measurements of the daughters in the chamber were made with filters inserted directly into the chamber. All flow rates for sampling were 1·08 l. min^{-1}. The humidity was measured with a thermistor psychrometer.

Two experiments were conducted: experiment 1 used an atmosphere with a dew point of 27° Fahrenheit, and experiment 2 used an atmosphere with a dew point of 47° Fahrenheit. For both experiments the chamber flow was 180 l. min^{-1} and the radon concentration was about $1·5 \times 10^{-8}$ Ci l.$^{-1}$ with the ratio of radium A atoms to radium B atoms at about 2·4 : 1. There was little radium C. In both cases, the air temperature was 78° Fahrenheit.

To study the electrical charge state of the radium A, samples were drawn through a condenser with an electrical field up to 50,000 Vm^{-1}. Radium A was undisturbed in passage through this condenser, indicating that the radium A ions were neutralized to uncharged atoms because of the high radon concentration.

Townsend[5] derived an equation describing the penetration of diffusing particles drawn through a cylindrical tube, and this equation was more accurately calculated by Gormley and Kennedy[8]. The relationship can be expressed as

$$F = 0{\cdot}819 \exp(-3{\cdot}66\pi D\eta) + 0{\cdot}0975 \exp(-22{\cdot}3\pi D\eta) + 0{\cdot}0325 \exp(-58{\cdot}6\pi D\eta)$$

with F the penetration fraction, D the diffusion coefficient of the diffusing material and η equal to the length of the tube divided by the volumetric flow rate through the tube. Because the last two exponential terms are unimportant except very close to the entrance of the tube, this relationship yields a straight line for penetration fractions less than about 0·8 when the logarithm of penetration is plotted against the parameter η. The slope of this line is proportional to the diffusion coefficient.

To analyse the data collected in these experiments, the concentration of radium A based on each sample was corrected for the radon decay in the tube and then normalized by dividing by the concentration of radium A measured with the chamber sample (zero diffusion length). The corresponding variances and standard deviations were also calculated. These experimental data were fitted by the method of weighted least squares to a simple exponential with the zero-length intercept equal to 0·819.

The calculated penetration fractions and their standard deviations for the two experiments are plotted in Fig. 1 as percentage penetration. Also shown are the experimental points reported by Chamberlain and Dyson[2] for the thoron daughter ^{212}Pb, called thorium B, which they used to confirm their calculation that the diffusion coefficient should be 0·054 cm^2 s^{-1}.

The diffusion coefficient calculated in experiment 1 was 0·047 cm^2 s^{-1}, which is similar to the value given by Wellisch[4]. The diffusion coefficient calculated from the

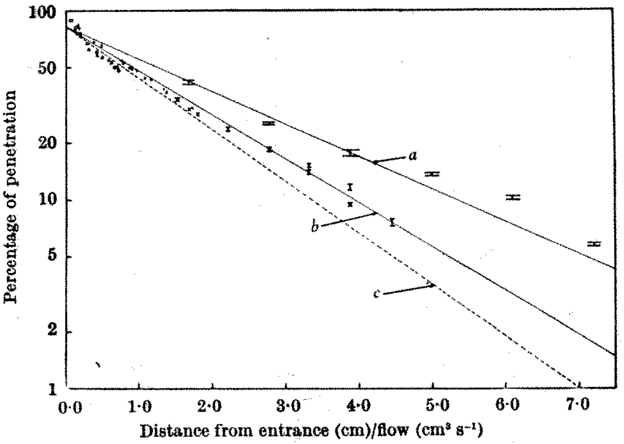

Fig. 1. Experimental data and standard deviations with the fitted theoretical lines for the percentage of penetration of radium A passing through a diffusion tube. The data points and theoretical line reported by Chamberlain and Dyson[2] (referred to here as $C+D$) are also given. The temperature of the dew point is indicated as DP. a, $D=0{\cdot}034$ cm^2 s^{-1} (DP = 47° Fahrenheit); b, $D=0{\cdot}047$ cm^2 s^{-1} (DP = 27° Fahrenheit); c, $D=0{\cdot}054$ cm^2 s^{-1} ($C+D$).

Symbol	Flow (cm^3 s^{-1})	Tube diameter (cm)	Source
●	16·6	0·4	$C+D$
×	33·3	1·8	$C+D$
△	83·3	0·4	$C+D$
○	83·3	1·8	$C+D$
I	18·0	0·7	Experiment 1
⌶	18·0	0·5	Experiment 2

data of experiment 2 was 0 034 cm^2 s^{-1} The principal difference between these two experiments was the absolute humidity, which, when expressed as the temperature of the dew point, was 27° Fahrenheit and 42° Fahrenheit, respectively

Tyndall[9] predicted that polar molecules, such as water, would tend to cluster around ions such as the initially charged radon daughters This type of clustering may explain the apparent diminution of the radon daughter diffusion coefficient with increased absolute humidity Possibly chemical reactions such as the formation of oxides are involved

These diffusion coefficient measurements indicate that there is a need for a more thorough study of the diffusion coefficient of radon daughters in various conditions, with special concern for the absolute humidity

This work was undertaken during the tenure of a US Atomic Energy Commission fellowship in the Department of Radiation Biology and Biophysics, University of Rochester, New York

THE SOLID STATE

Particle Coarsening in the Solid State

PARTICLE growth in supersaturated solutions has stimulated much theoretical and experimental work, but less attention has been paid to the subsequent reaction of particle coarsening in a matrix of solute content in local equilibrium with small particles The driving force for coarsening is the decrease in total energy accompanying a reduction of particle/matrix interfacial area Coarsening is controlled either by the diffusion of solute down the concentration gradient between neighbouring particles of differing size, or by the difficulty of assimilating solute atoms at the interface of a growing particle

It has been shown[1-3] that a particle dispersion with an initial mean radius $\bar{r}_0$ at the beginning of the coarsening process will usually have at time t a mean radius $\bar{r}$ given by an equation of the form

$$\bar{r}^n - \bar{r}^n_0 = At \tag{1}$$

where n and A are constants The value of n depends on the mechanism controlling the coarsening process The condition that $n = 2$ indicates an interface controlled reaction[1] while $n = 3$ indicates volume solute diffusion control[1,3] Speight[4] has recently proposed a model for coarsening of particles in grain boundaries, in which $n = 4$ In the latter case growth takes place by grain boundary rather than volume diffusion The constant A contains various parameters which depend on the precise mechanism

A difficulty with reactions following equation (1) is that of determining the index n It is common practice to plot the logarithm of the measured parameter versus the logarithm of the time, thus neglecting the constant $\bar{r}_0$ in equation (1) If $\bar{r}_0$ is small compared with $\bar{r}$ for the time interval of interest, then n is equal to the reciprocal of the slope If $\bar{r}_0$ is not negligible, however, the slope of a log $\bar{r}$ versus log t plot is no longer inversely proportional to n and the slope tends towards zero at small t as $\bar{r}$ tends towards $\bar{r}_0$ This difficulty is enhanced when such log–log plots show breaks or changes of slope which are usually interpreted as indicating changes in mechanism or rate

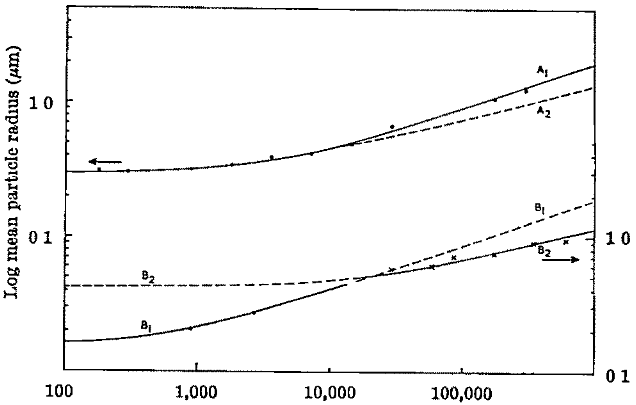

Fig 1 Coarsening of iron carbide particles in steel

Data for coarsening of iron carbide (Fe_3C) in a 0 3 per cent by weight carbon steel at 720° C and at 675° C are presented in Fig 1 as plots of log $\bar{r}$ versus log time The radii plotted were obtained from the procedure given by Fullman[5] for the sectioning of uniform spheres of radius r_u If the shape of the size distribution histogram of $r/\bar{r}$ is invariant with time, as it should be for a coarsening reaction, then no error is introduced in the determination of n by utilizing r_u from the uniform sphere formula rather than $\bar{r}$ values

Curve A_1, showing the data for coarsening at 720° C, has a slope near to zero at small t The slope gradually increases with t until it corresponds to an n value of 3 at $t \simeq 2 \times 10^4$ s, when $\bar{r}^3 \simeq 6\bar{r}_0^3$ The solid curve A_1 was not drawn as a best fit through the data points but was calculated from equation (1), using values of $\bar{r}_0$ and A derived from a plot of $\bar{r}^3$ versus t Curve A_2 was calculated from equation (1) using values of $\bar{r}_0$ and A derived from a plot of $\bar{r}^4$ versus t The two curves are indistinguishable for $t < 10^4$ s Clearly the data best fit equation (1) with $n = 3$ This n value indicates that a matrix diffusion process is the activated step controlling coarsening, possibly carbon diffusion, although co-operative diffusion of iron cannot be excluded[6]

Table 1 VALUES OF THE CONSTANTS GIVEN BY THE NON-LINEAR REGRESSION ANALYSIS

Temp (°C)	n	A cm^n s^{-1}	r_0 cm
720	3 1	0 73 × 10^{-17}	0 28 × 10^{-4}
675	3 09	0 29 × 10^{-17}	0 21 × 10^{-4}
675	4 11	0 58 × 10^{-22}	0 49 × 10^{-4}

To verify this interpretation of the log–log plot the data were analysed using a non-linear regression analysis on an IBM 760/350 computer This gave a value of $n = 3$ 1 for the whole of the time span investigated The other constants are given in Table 1, but their values as determined from a non-linear analysis are probably not as accurate as would be obtained using a linear analysis with the correct n value

The data for coarsening at 675° C—curves B_1 and B_2—show a break in the log–log plot Treating each section as a linear relation gives slopes of 0 34 and 0 22 It is possible that the lower slope for $t > 2 \times 10^4$ s is a transient effect caused by the neglect of a new (and greater) $\bar{r}_0$ term and that the time dependence is the same as in the early stages The data were split at the break in the plot, and application of a non-linear regression analysis for each half showed that the data for shorter times were best fitted by an n value of 3.09 and the data for longer times by $n = 4.11$. These results are reasonably close to possible ideal values, indicating a real change in reaction mechanism.

The constants $\bar{r}_0$ and A were obtained from plots of $\bar{r}^3$ and $\bar{r}^4$ versus t for each half of the data, and curves B_1 and B_2 were calculated from equation (1) with the constants appropriate to $n = 3$ for the shorter time data and $n = 4$ for the longer time data. Clearly all the data cannot be described by a single curve of the form of equation (1). The complementary curves using the values of $\bar{r}_0$ and A calculated from $n = 4$ for the shorter time data and $n = 3$ for the longer time are not shown, but do not provide a fit with the data. Many of the carbide particles were seen to lie at sub-grain boundaries in both steels at all ageing times, and, as already indicated[4], a value of $n = 4$ suggests that a grain boundary diffusion growth process becomes predominant at long ageing times.

We have found similar behaviour in other steels and we are investigating the factors affecting the transition from matrix to grain boundary diffusion control more closely as a function of temperature, chemical composition and microstructure.

We thank R. I. Iles for some of the experimental determinations, and Mrs Janice Rolls for advice on computer procedures.

Optical Study of Particle Size of Montmorillonite with Various Adsorbed Cations

In sodium-montmorillonite suspensions the single clay plates are largely separated from each other, whereas in calcium-montmorillonite they form aggregates or tactoids containing from 5 to 15 parallel plates[1]. This property of calcium-montmorillonite may affect its swelling[2], negative adsorption[3] and ion exchange kinetics and equilibrium[4,5].

Because of this difference in particle size, dilute sodium-montmorillonite suspensions are less opaque—that is, they absorb and scatter less light in the visible range—than calcium-montmorillonite suspensions[2,5–7]. Differences in the opacity also exist between dilute suspensions of montmorillonite with other adsorbed cations. It is known that, in general, the absorption and scattering of light is largely dependent on the size of the colloidal particles, and can be used to estimate particle size. In fact, optical methods have been used to estimate the orientation and the shape of particles in pure sodium-montmorillonite suspensions[6,8]. This has not, however, been done for mono-ionic montmorillonite with other adsorbed ions. We therefore decided to study systematically the optical properties of a series of montmorillonite suspensions with different adsorbed cations, and to use the findings to estimate the particle size.

We found that the relative size of the average montmorillonite particle depends on the type of adsorbed ion. The size tends to increase systematically with the position of the ion in the lyotropic series, probably because of the formation of tactoids containing greater numbers of clay plates. Even the monovalent ions were observed to induce tactoid formation, so this process seems to be the rule for montmorillonite in any ionic form rather than an exception for calcium-montmorillonite, as previously assumed.

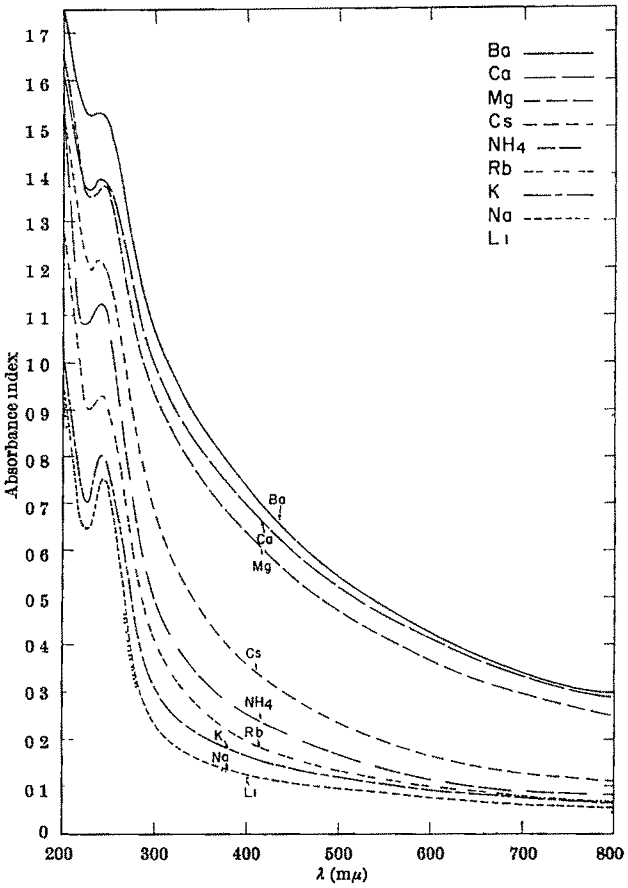

Fig. 1. The absorbance index (optical density for unit optical path length) of dilute, mono-ionic montmorillonite suspensions (250 mg clay l.$^{-1}$) in the wavelength range 200–800 mμ. Notice the selective absorption peak at 245 mμ, and the absence of such selective light absorption in the visible range.

Mono-ionic, essentially salt-free, montmorillonite suspensions of known clay concentration were prepared, as described in detail elsewhere[9], and their optical density was determined in the range 200–800 mμ with a Cary model 15 recording spectrophotometer. From the results, the absorbance index K, defined as the optical density for unit path length, was calculated.

Fig. 1 shows the spectra of montmorillonite saturated with Li^+, Na^+, K^+, NH_4^+, Rb^+, Cs^+, Mg^{++}, Ca^{++} and Ba^{++}. All the suspensions had the same clay concentration of 250 mg l.$^{-1}$. Similar spectra were obtained for other clay concentrations in the range up to 500 mg l.$^{-1}$. It can be seen that the adsorbed cation does not affect the general shape of the spectrum, but the higher the adsorbed ion in the so-called lyotropic series, the higher is the absorbance index of the suspension at a given wavelength in the visible range. Because the crystallographic composition and the concentration of the clay are the same in all the suspensions, and because the ions *per se* do not adsorb or scatter light in the visible range, it seems that changes in the average particle size of the clay can be the only possible cause for the observed differences in K.

We will now attempt to estimate the relative sizes of the clay particles in a more quantitative way. In the experimental system used, little of the scattered light entered the measured beam, so the absorbance index measured the total decrease in light intensity resulting from both light absorption by the particles and scattering from their surfaces. Thus[10]

$$K = t + d \qquad (1)$$

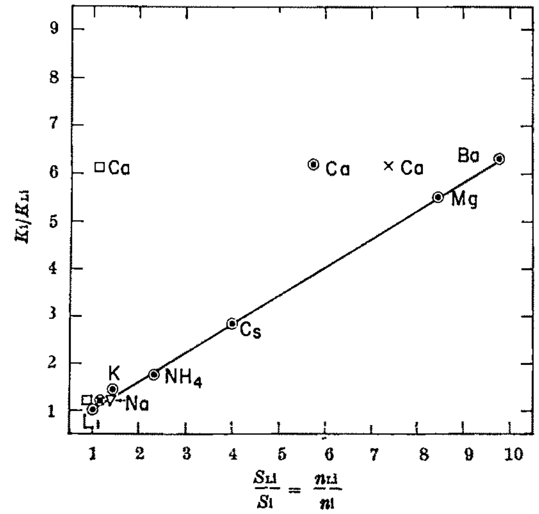

Fig 2 Correlation between absorbance index (K) ratios and specific surface area (S) ratios K values were taken from Fig 1 at 700 mμ S values, determined by the negative adsorption method, were taken from the literature and serve to estimate the relative number (n) of plates per tactoid for montmorillonite in various ionic forms Values for Li–montmorillonite were taken as the basis in all the calculations Sources for S values ○, Edwards, Posner and Quirk[13], ×, Edwards and Quirk[3], □, Bolt and Warkentin[14], ▽, Schofield[15]

where t and d are the scattering and absorption contributions respectively It is known, however, that clays do not absorb light in the visible range[11] We confirmed this for the montmorillonite suspensions we used by measuring separately the light absorbance component of several suspensions using a total diffuse reflectance accessory in the Cary spectrophotometer We found that absorbance was negligible compared with scattering As a first approximation, equation (1) thus reduces to

$$K = t \tag{2}$$

Furthermore, t is related to the turbidity τ by $t = 0\ 4343\tau$. The turbidity is proportional to the particle weight M and the concentration c as follows

$$\tau = HcM \tag{3}$$

where H is a constant depending on the optical properties of the particles and the solvent[12] This relationship can then be used to estimate the particle weight from the optical measurements

The montmorillonite tactoids consist of several parallel clay plates separated from each other by water layers of 9–10 Å thickness[3] For such an arrangement the composite particle weight is simply given by

$$M = mn \tag{4}$$

where m is the average weight of a single clay plate and n the average number of plates in a tactoid

Using equations (2), (3) and (4) we can calculate the ratio of the absorbance indices at a given wavelength of two suspensions having the same clay concentration but different adsorbed ions (1) and (2), and we get

$$\frac{K_1}{K_2} = \frac{H_1 n_1}{H_2 n_2} \tag{5}$$

We see that the absorbance index ratio is proportional to the relative size of the tactoids

Because the lithium–montmorillonite suspension gave the smallest K values, it apparently had the smallest n, assumed to be equal to one, and it was used as the reference (ion 2) for the calculations of the relative average tactoid sizes in other ionic forms by use of equation (5) and data from Fig 1 To check these calculations we estimated the relative tactoid sizes by another, independent, method We assumed, following Edwards and Quirk[3], that the existence of tactoids in the suspension decreases the volume of exclusion of chloride ions Thus the surface area S calculated from the measured volume of exclusion is also decreased, being in inverse proportion to the tactoid size More explicitly we write $S = S_t/n$ where S_t is the total surface area The relative average tactoid size in two different ionic forms can then be found from the relationship $n_1/n_2 = S_2/S_1$ For the calculations, we used surface area data reported in refs 3, 13, 14 and 15, again with Li as the reference form Finally we plotted the K ratios versus the n ratios, as shown in Fig 2 Apart from the deviations of calcium, a rather good correlation is found between the two sets of values This fact lends support to the hypothesis that the average particle size of montmorillonite in suspension is affected by the type of adsorbed ion This is a hitherto unknown effect of the exchangeable ion on the particle size of montmorillonite, and it should help in understanding the many other properties of clay suspensions that depend on the average particle size A possible cause of the great discrepancies between measured surface areas of calcium–montmorillonite reported in the literature, for example, refs 3, 13 and 14, and reflected in Fig 2, may be variations in the tactoid size of the clays studied, resulting from different materials or preparation methods

We thank Mr D Banin for his assistance in the optical measurements

CHEMISTRY

Co-ordination Compounds of Alkali Metals, with 8-Hydroxyquinoline and Isonitrosoacetophenone

As part of a study of the uptake and transport of alkali metals by plants, we are investigating their co-ordination chemistry in an attempt to obtain compounds in which the alkali metal is unequivocally co-ordinated Earlier reports[1] on compounds formed with salicylaldehyde (HL) suggested formulae of the form $ML n$HL In this system we have found n to be continuously variable, only the salt ML being definitely isolated But with the ligands 8-hydroxyquinoline and isonitrosoacetophenone we have succeeded in isolating crystalline complexes ML HL or ML 2HL, the product formed depends primarily on the radius of the metal and second on the reaction conditions

Addition of the ligand 8-hydroxyquinoline (HQ) to a suspension of metal hydroxide in absolute ethanol—it is essential that water be absent—gave *M*Q HQ for *M* = Li, Na and K but *M*Q 2HQ for *M* = Rb and Cs, irrespective of the ratios of reactants

For the ligand isonitroacetophenone (I), HL, the reactions took place in ethanol between the metal hydroxide and the ligand

Whatever the proportions of the reactants lithium and caesium gave only LiL and CsL HL, respectively For the alkali metals of intermediate radius *M*L or *M*L HL was formed according to the conditions For mole ratios 1 1, with potassium or rubidium in slight excess, the yellow ethanol solution deposits red flaky crystals of KL or RbL These crystals give red solutions in dimethyl formamide or *N*-methylpyrolidone If they are warmed in ethanol or benzene with excess HL, yellow needles of KL HL or RbL HL separate These give a yellow solution in *N*-methylpyrolidone In other organic solvents the red flakes *M*L are deposited, and in water the ligand separates leaving a yellow solution of the salt The sodium salt NaL is obtained as a cream coloured precipitate, when this is suspended in benzene and treated with HL a gelatinous white substance is formed which when dried was analysed as NaL HL

The new compounds are summarized in Table 1 All gave satisfactory chemical analyses Entries for the crystal system indicate that the molecular weights have been determined by X-ray studies on single crystals, KL HL is isomorphous with RbL HL, RbQ 2HQ and CsQ 2HQ are isomorphous No information about molecular symmetry can be deduced from any of the space groups

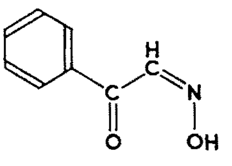
Table 1 PROPERTIES OF THE COMPOUNDS

Compound	Colour	m.p (dec)	Crystal system
LiL	Yellow	180	
NaL	Cream	150	
KL	Red	95	
RbL	Red	108	
NaL HL	White	105	
KL HL	Orange-yellow	87	Triclinic }
RbL HL	Yellow	110	Triclinic }
CsL HL	Yellow	85	Monoclinic
LiQ HQ	Pale yellow	130	Hexagonal
NaQ HQ	Pale yellow	115	
KQ HQ	Pale yellow	150	Monoclinic
RbQ 2HQ	Pale yellow	120	Triclinic }
CsQ 2HQ	Pale yellow	110	Triclinic }

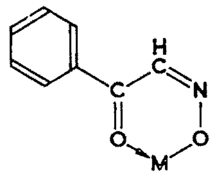
The infrared spectra of all the compounds have been measured in Nujol mulls, as have those of HL and HQ under the same conditions All the alkali metal HQ compounds in Table 1 gave similar spectra They differed from that of the ligand molecule by the absence of a weak broad band at 3,200 cm^{-1} (probably O–H stretching) and by an increase in the number of bands in the 1,570–1,610 cm^{-1} region from one in the ligand to four in caesium compound The spectra were similar to those of the magnesium chelate MgQ$_2$ (ref 2)

The infrared spectra of the *M*L compounds are similar to one another and differ from that of the ligand by the absence of the hydroxyl band at 3,260 cm^{-1} and a shift in the carbonyl peak from 1,680 cm^{-1} to 1,640, 1,635, 1,625 and 1,610 cm^{-1} for Li, Na, K and Rb, respectively This suggests a chelate form (II) for the *M*L compounds.

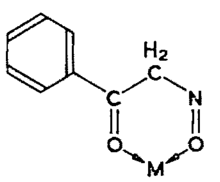
The infrared spectrum of the compound NaL HL closely resembles that of HL, in particular in having a hydroxyl band at 3,200 cm^{-1} and a carbonyl stretch at 1,675 cm^{-1} This evidence is equally consistent either with a second molecule being chelated in form I or with the product being a mixture of NaL and HL Potassium, rubidium and caesium compounds, *M*L HL, have spectra distinct from those of *M*L and of the ligand, no hydroxyl frequency appears and all three show a sharp band at 1,635 cm^{-1} Another sharp band appears at 1,660, 1,655 and 1,650 cm^{-1} in the K, Rb and Cs compounds, respectively These spectra are consistent either with the alkali metal being chelated by one anionic ligand as in (II) and a second neutral one as in (III), or with the hydrogen bonded structure (IV) The latter would make both ligands equivalent and might more satisfactorily explain the colour changes on co-ordination by a second ligand.



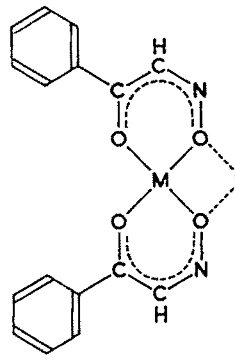
(I)



(II)



(III)



(IV)

Preliminary experiments with mixed ligands, giving, for example, KL HQ, have yielded promising results and will be reported when the compounds are fully characterized

Molecular Conformation of Thymidine and a Comparison with some Electron Spin Resonance Results

The determination of the structure of thymidine (C10 N2 O5 H14, Fig 1) was undertaken as part of a series of structure determinations of nucleic acid components Thymidine is the only nucleoside which has been studied[1] by electron spin resonance of irradiated single crystals and, in particular, the orientation of the pyrimidine ring has been predicted from these studies Radiation effects on thymine make an important contribution to the spectra obtained in electron spin resonance experiments on irradiated deoxyribose nucleic acid[2]

Crystals were obtained from aqueous solution The unit cell is orthorhombic with dimensions $a = 4\ 86$ Å, $b = 13\ 91$ Å and $c = 16\ 32$ Å The space group is $P2_12_12_1$ and there are four molecules in each cell These results are in good agreement with those found by Furberg[3] In all, 1,203 reflexions were observed using molybdenum $K\alpha$ radiation The data were collected using the Hilger and Watts linear diffractometer

The structure was determined by the method described by Tollin and Cochran[4]. The function $I(\Theta\ \varphi)$ (ref 4) was calculated using the 100 largest sharpened $|F|^2$ values and is shown in Fig 2. This map indicated that the plane of the pyrimidine ring has a normal defined by $\Theta = 90°$, $\varphi = 43.5°$, where Θ and φ are the spherical polar angles with respect to the axial set a, b, c. The orientation of the pyrimidine ring within this plane was obtained from the section in this orientation through the origin of the Patterson function. The position of the ring in the unit cell was determined using the Q-functions defined by Tollin[5].

A three-dimensional electron density map, using the magnitudes of the observed structure factors and phases calculated from the atoms of the pyrimidine ring alone, revealed the positions of the remaining atoms. Fourier refinement on the a-axis projection and least-squares refinement using the three-dimensional data led to a structure giving an R factor, where

$$R = \frac{\Sigma ||F_0| - |F_c||}{\Sigma |F_0|},$$

of 0.13 using isotropic temperature parameters. The determination of the positions of the hydrogen atoms from a three-dimensional difference Fourier and subsequent refinement with anisotropic temperature parameters gave a final structure which led to an R factor of 0.08 for the observed reflexions. These results together with the details of the structure determination will be published later, but a number of observations can be made at present.

The orientation of the pyrimidine ring is given by $\Theta = 89°$, $\varphi = 45°$, the maximum deviation from this plane being 0.015 Å, which confirms the electron spin resonance results which predict angles of approximately $\Theta = 90°$, $\varphi = 45°$. The conformation of the sugar residue relative to the pyrimidine ring is best described by the torsion angle φ_{CN} defined by Donohue and Trueblood[6] which has a value in this case of $-39°$, the sugar being in the *anti* conformation with respect to the pyrimidine ring. This value agrees with previous results for pyrimidine nucleosides and nucleotides[7]. Moreover, in all nucleosides and nucleotides the sugar ring has one atom, either C2′ or C3′, displaced from the mean plane of the other four ring atoms. In thymidine the atom C3′ is displaced 0.5 Å on the opposite side of the plane from the atom C5′ (the *exo* conformation). Only one other nucleoside or nucleotide—deoxyadenosine[8]—has this displaced atom in the *exo* position. The bond C5′–O5′ is *gauche* with respect to the C4′–O1′ bond and *trans* with respect to the C4′–C3′ bond[9].

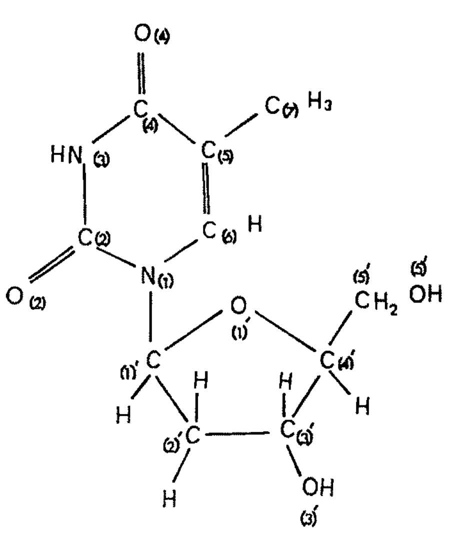

Fig. 1. The molecular formula of thymidine and the conventional numbering system.

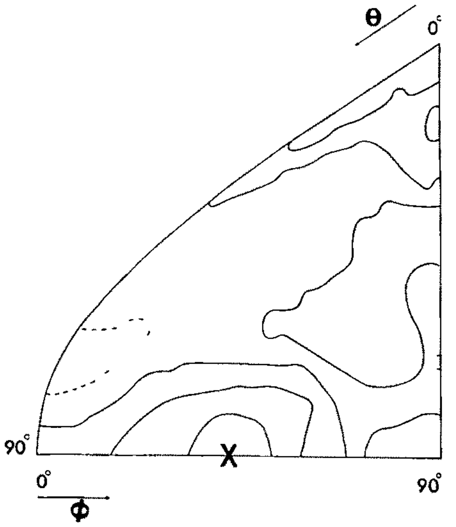

Fig 2. The $I(\Theta,\varphi)$ function. Contours are drawn at equal intervals. The lowest contour is dashed. The cross (×) marks the position of largest peak.

These results can be compared with the conformation of the molecule in calcium thymidilate[10] in which $\varphi_{CN} = -48°$, the displaced atom is C3′ in the *endo* position and the conformation of the bond C5′–O5′ is *gauche-gauche*.

Pruden *et al*[1] state in their conclusions from the electron spin resonance studies of irradiated thymidine that "The equivalence of the coupling of the $C_{(5)}-CH_3$ protons proves that the methyl group is rotating about the C—C bond". The hydrogen atoms of the methyl group are well resolved in the three-dimensional difference map, so we conclude that in the undamaged crystals the methyl group is not rotating.

BIOCHEMISTRY

Growth Hormone in Human Development

Many investigators have established that changes occur in the structure of enzymes and other proteins during development. For example, Cahn *et al* have shown changes in the isoenzymes of lactic dehydrogenase (LDH)[1], and Korber was the first to recognize that foetal haemoglobin is more resistant to alkali than maternal haemoglobin[2]

There is thus a precedent for the possibility that human peptide hormones undergo changes during foetal development To pursue this question, complement fixation, a technique extremely sensitive to slight changes in antigenic structure[3-5], was employed to compare growth hormone in the human foetus and human adult

Adult human growth hormone (*HS*-496 *A*), prepared by the method of Wilhelmi[6], was purified by column chromatography on diethyl amino-ethyl cellulose in 0 02 M borate–NaOH buffer, *p*H 8 0 Three protein peaks were obtained Peak *A*, the purified antigen in this study contained 2 IU/mg of growth activity[7] and 6 8 IU/mg of crop gland stimulating activity[8]

Thirteen pituitaries, and a small piece of foetal fibrous connective tissue from the area around the sella turcica, used as a control, were obtained at autopsy from foetuses ranging from 12 weeks (crown–rump, 8 cm) to 40 weeks old, and were frozen at − 20° C Before use they were thawed, weighed to the nearest mg, and individually extracted in 1 ml of ice cold isotonic *tris* buffer, *p*H 7 4, by homogenization in a glass tissue grinder[9]

After standing for 1–2 h at 2° C the homogenates were centrifuged at 10,000*g* for 10 min at 4° C The supernatant solutions were decanted and used for immunological studies without further purification

A single anti-adult human growth hormone A rabbit serum (*RA* 452*B*-7) was used It was prepared as previously described and diluted 1 1,500 before use[10] No evidence of immunochemical heterogeneity of the antiserum was shown by double diffusion in agar In addition, only one complement fixation peak was observed with the antiserum even when there was a great excess of antigen against human growth hormone or a crude extract of adult human pituitary glands

Quantitative micro-complement (*C′*) fixation was performed according to Wasserman and Levine[11] The *C′* fixation curves (Fig 1) obtained with antiserum *RA* 452*B*-7 (diluted 1 1,500) and *HS*-496 *A* and thirteen crude extracts of human foetal pituitary glands from 12 to 40 weeks of gestation are all superimposable These curves show that 85–88 per cent of complement is fixed at the zone of antibody–antigen equivalence (0 08 µg of antigen) No complement was fixed when foetal fibrous tissue was used as the antigen

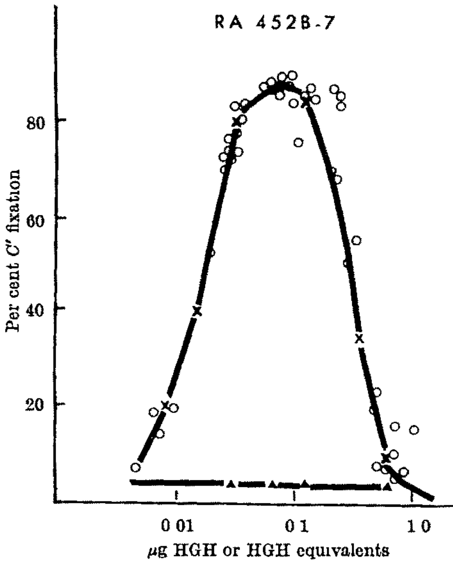

Fig 1 *C′* fixation curves obtained with adult human growth hormone *A* (HGH-*A*) (×) or with a crude extract of any one of thirteen foetal pituitaries (○) and antiserum 452*B*-7, diluted 1 1,500 The curves are drawn with their points of equivalence at the same antigen concentration The maximum *C′* fixations obtained with purified HGH-*A* and the crude foetal pituitary extracts are identical No *C′* fixation was obtained when a crude extract of foetal fibrous tissue was used as an antigen (▲)

The question of whether or not there are specific foetal hormones may have important implications for medicine and biology If they do exist, there may be abnormalities of their regulation, analogous to some of the haemoglobinopathies, which have not yet been recognized Also, the persistence of the varying levels of the foetal hormone in the adult may account for some of the hormone-like substances which have been detected in adult serum[12,13] On the other hand, the immutability of growth hormone during development may be equally significant

This experiment does not conclusively exclude the possibility that a specific foetal hormone exists It is possible that (*a*) areas of the peptide hormone other than those containing the antigenic determinants are structurally different, (*b*) growth hormones exist in the foetus which are so different antigenically that they do not react with the antiserum used in this experiment, and (*c*) earlier stages of development than those investigated have different growth hormone(s)

Further studies, including investigation of still younger foetuses and study of the primary structure of the peptide hormones, are necessary to elucidate the problem The present studies indicate that pituitaries of human foetuses contain a substance which is antigenically indistinguishable from purified adult growth hormone by quantitative complement

I thank Dr Lawrence Levine of Brandeis University and his staff, in whose laboratory part of this experiment was performed, and also Dr R B Hill for advice This investigation was supported by a pathology training grant

Pink Spot as a Diagnostic Test in Schizophrenia

THE first report of the presence of DMPEA in the urine of schizophrenic patients[1] was followed by other confirmatory[2-4] and conflicting[5-9] results We have used different methods to give a better resolution of the substance Recently a new technique for the isolation and identification of the pink spot was described[10] This seems to be a specific method by which at least seven constituents of the pink spot (DMPEA being only a minor one) have been discovered

Only one of the previous investigations[4] involved the chromatographic procedure first described by Friedhoff and van Winkle, and the pink spot has regularly been found to be absent from normal individuals, while it was present in varying proportions in a group of schizophrenic patients We wished to verify whether the pink spot—identified by a special method and consisting of many other compounds as well as DMPEA—was specific for schizophrenia If it was, this would signify that, as well as the production of DMPEA, a greater disturbance of amine metabolism could be involved in schizophrenia[11], this would prove the validity of our method as a diagnostic test

We treated the urine of 221 individuals according to the extraction and chromatographic method of Friedhoff and van Winkle Of these, 106 cases had psychic disorders, eighty-eight were physically ill and twenty-seven were normal subjects Twenty hour urine samples were collected in the first 24 h after admission to hospital, before the beginning of any treatment The patients had received no drugs for periods of from 3 weeks to several months Of the 106 patients with psychic disorders, fifty-one were diagnosed as schizophrenics by three psychiatrists The remaining fifty-five patients were divided as follows sixteen had neurotic disorders, fifteen had psychopathic disorders—seven mania and nine endogenous depression—and eight had involutional or artheriosclerotic dementia Of the patients with physical disorders, nine were suffering from Parkinson's disease, and the rest were cardiac, rheumatic or digestive cases

The pink spot was present in the urine of twenty-three out of fifty-one schizophrenics (45 per cent), and three cases were impossible to assess We could not find any significant correlation between the form of schizophrenia and the frequency of the pink spot[4] As for the urine of the other seventeen subjects, only in one case of Parkinsonism did we obtain a positive reaction and in another case with the same diagnosis the reaction was impossible to assess The presence of DMPEA in the urine of patients with Parkinson's disease has been reported before[12]

We consider these results to confirm the chromatographic technique of Friedhoff and van Winkle as a useful diagnostic method If the pink spot consists of at least seven amines, and if it is specific for schizophrenia and possibly for a few restrained disturbances of the basal ganglia as well, then a certain common derangement of amine metabolism, including the production of DMPEA, occurs in such cases These data agree with the high concentration of catecholamines and dopamine in subcortical structures and with the Parkinson-like symptoms induced by psychoactive drugs which have a depressant action on these structures[13]

We thank Professor Arnold J Friedhoff for his help

Effects of Enzymes on the Pharmacology of Isolated Organs

A NUMBER of reports[1-5] have described the effects of enzymes on the mechanical responses of isolated muscles obtained in response to drugs and other stimuli Enzyme treatment, however, does not always provide a way of examining the nature of drug receptors because the drug receptor interaction is only the first of a chain of events leading to contraction If the predominant enzyme effect is on a stage of the process following the drug receptor interaction, no information about the nature of the receptor can be adduced. In such cases a proportional reduction in the response to several different stimuli might be expected We wish to present our own findings as a case in point

The effects of tryptic digestion on the sensitivity of frog rectus abdominis muscle to acetylcholine (stimulus via drug receptors) and to direct current (stimulus bypassing drug receptors) were studied Both the aggregate (contracture) and the discrete (single muscle cell membrane potentials) responses were monitored by conventional means The results show that although classical stimulus-effect relationships are maintained after enzyme treatment (Fig 1), the responses to both acetylcholine and d c stimulus deteriorate at comparable rates (Fig 2) with continued exposure to trypsin

Furthermore, this relationship holds for all concentrations of trypsin which produce a measurable desensitization of the muscle There is concomitant obliteration of muscle cell membrane potentials successively deeper within the preparation (Table 1) Histological sections confirm this invasive deterioration of cellular structures

Our findings indicate that, for the rectus muscle and trypsin, the penultimate process of contracture is affected

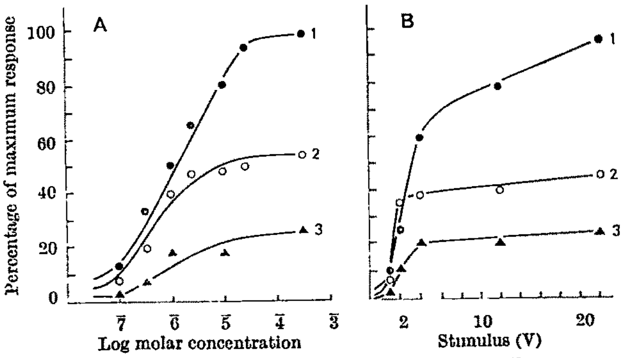

Fig 1 Effect of digestion by 0 1 mg/ml of trypsin on the response of frog rectus abdominis to acetylcholine (*A*) and to electrical stimulation (*B*) 1, Control, 2, after 10 min digestion, 3, after 20 min digestion

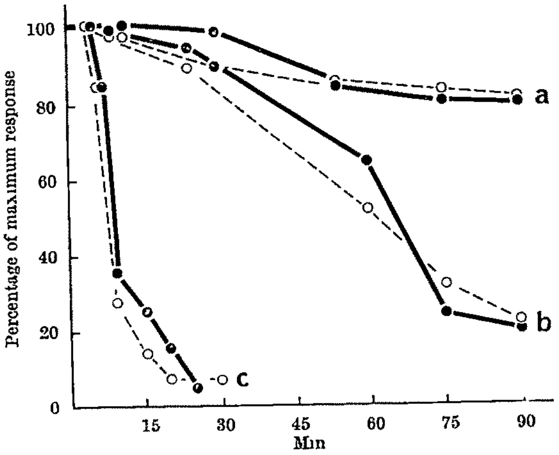

Fig 2 Change in sensitivity of frog rectus abdominis muscle to acetylcholine (——) and to electrical stimulus (– – – –) as a function of time and of enzyme concentration *a*, 0 01 mg/ml of trypsin, *b*, 0 1 mg/ml of trypsin, *c*, 1 mg/ml of trypsin

Table 1 LATENT PERIOD FOR REDUCTION OF MUSCLE CELL MEMBRANE POTENTIALS FROM INITIAL LEVELS (−65 TO −78 mV) TO −10 TO −20 mV AT VARIOUS LOCATIONS WITHIN A RECTUS MUSCLE TREATED WITH 0 1 mg/ml OF TRYPSIN

Depth (μ)	No of observations	Time of depolarization (min)
100	5	2 5–3 5
100–400	5	7 0–14
400–600	3	24–45

to the extent that precludes an assessment of specific effects of the enzyme on drug receptors We suggest that a similar examination of other systems may show that this is a common limitation to such studies

Production of Renin by *in vitro* Cultures of Human Chorion and Uterine Muscle

Renin-like enzymes have been extracted from a variety of tissues other than the kidney, including cat placenta[1], rabbit uterine muscle and placenta[2–4], hog aorta[5] and mouse submaxillary gland[6,7]

In situ synthesis has been claimed in pregnant rabbit uteri on the basis of the finding that bilateral nephrectomy does not lead to depletion of renin from this tissue[8] Proof of synthesis by *in vitro* culture techniques has, however, only been shown in renal cortical cells[9,10], and even in these studies renin production was poor, with supernatant concentrations below those normal in plasma In addition, evidence of renin production through sub-culture was not provided

The description by Brown *et al* [11] of high concentrations of renin in human amniotic fluid has led us to measure the renin content of maternal and foetal tissue, and to reveal that chorion laeve had a higher content per wet weight than myometrium, decidua, amnion and placenta Concentration in chorion was four times that of either amnion or liquor amnii, and 100 times that of placenta and uterine muscle These findings suggested that chorion could be an important site of renin synthesis We report here confirmation of this suggestion, together with evidence that cells in human uterine muscle are capable of producing renin during *in vitro* culture

Tissues were collected from five normal pregnant subjects at the end of gestation Four of the five subjects were delivered by caesarean section before the onset of labour, and one subject was delivered vaginally Peripheral chorion (chorion laeve) was collected by stripping amnion from chorion, and chorion was also dissected from the foetal surface of the placenta (chorion plate) Placenta itself was sampled from the maternal surface, and uterine muscle and decidua were dissected at caesarean section

Tissues were washed five times in an antibiotic solution of 10^4 μg/ml of kanamycin and 500 μg/ml of fungizone in 'Dulbecco' phosphate buffer (personal communication from Von der Borch) Tissues were minced into small fragments (approximately 1 mm^3) and explanted into chick plasma clots in Leighton tubes The culture medium consisted of 6 per cent chick embryo extract, 40 per cent human AB serum and 54 per cent tissue culture medium 199 (Commonwealth Serum Laboratories) The cultures were maintained at 37° C and the medium was changed every 48 or 72 h and replaced with 2 ml of fresh medium After each change, the culture medium was frozen and stored, together with a similar volume of control culture medium not exposed to the tissue culture When confluent growth had occurred—usually after 7–10 days—sub-cultures were made by trypsinization with 0 25 per cent trypsin and resuspension of the cells in the culture medium Placenta was taken from two subjects, chorion laeve from four subjects, chorion plate from two subjects, amnion from three subjects and uterine muscle from two subjects. All tissues were cultured at least in duplicate.

The growth of the tissue cultures is summarized in Table 1 In ten out of thirty-five primary cultures, no growth occurred In the remaining twenty-five cultures, some primary growth occurred, and eleven were suitable for sub-culture

Supernatants collected at each medium change were frozen for storage and control medium was sampled at the same time. The concentration of renin in selected samples was then assayed quantitatively by the technique described for plasma[12] In this method, renin is prepared free of endogenous substrate and then incubated in standard conditions with a constant amount of added substrate in an angiotensinase-free environment The velocity of angiotensin formation in the incubate was assayed using rat blood pressure, and specificity for renin was tested by the method used before[12], which is based on (*a*) the peptide nature of the end product, (*b*) consumption of substrate, and (*c*) antibody inactivation. Non-specific pressor and depressor responses were not encountered Renin was present in control media in approximately half the normal concentration in plasma[12], and this was subtracted accordingly in deriving renin production

Fig 1 shows the concentration of renin in supernatants of all cultures which displayed some growth. The six primary cultures of chorion consistently produced large amounts of renin into the media The time course of this production was similar for all cultures, with peak concentrations on days 5–9 The highest concentration achieved was 1,000 U/ml, approximately 100 times the usual concentration of renin[12] In five cultures a fall in renin production after day 9 was paralleled by a decline in the rate of growth. Renin production, nevertheless, continued at a lower level for 24 days Only one primary culture of chorion had a consistent growth rate throughout (closed squares, Fig 1), and this was successfully sub-cultured three times during a 55 day period, at which time supernatant concentrations were still reaching the concentrations displayed by the primary growth

Myometrium also produced large amounts of renin, but for an entirely different time course (Fig 1) Three of four cultures displayed grew well throughout, but each produced renin only after an initial interval of 10–15

Table 1

Tissue	No of cultures	Explant growth*		No of cultures sub-cultured	No of sub-cultures	Total time of culture (days)
Chorion laeve	10	No growth	4	—	—	—
		Fair growth	3	—	—	All 15 days
		Good growth	2	—	—	27, 27
		Excellent growth	1	1	3	55
Uterine muscle	5	No growth	1	—	—	—
		Fair growth	1	1	1	30
		Good growth	3	3	1, 1, 3	30, 27, 27
Placenta	4	Poor growth	2	—	—	20, 20
		Fair growth	2	—	—	24, 24
Amnion	6	No growth	1	—	—	—
		Good growth	2	2	1, 1	27, 27
		Excellent growth	3	3	2, 1, 1	27, 25, 25
Decidua	4	Poor growth	2	—	—	20, 20
		Fair growth	2	—	—	18, 18
Chorion plate	4	No growth	2	—	—	—
		Poor growth	1	—	—	—
		Good growth	1	1	2	57

* The terms poor, fair, good and excellent growth apply to the primary culture

These terms refer to the period of time in culture before outgrowth from the explant occurred Thus, with poor growth, outgrowth occurred after 10–14 days, fair growth occurred after 7–10 days, good growth after 3–7 days and excellent growth within 3 days

days, during which none was detected After the tenth day, renin concentration increased progressively, reaching a level 120 times that of normal plasma before sub-culture The fourth culture, which showed fair growth, is not shown in Fig 1, and produced no renin during 30 days of incubation Myometrium was successfully sub-cultured on two occasions and in each instance renin production continued

Placenta did not grow well, but two of the four cultures showed fair growth and produced some renin into supernatant The time course was similar to that for chorion, but at a much lower level No growth was adequate for sub-culture

Although amnion grew consistently well and was readily sub-cultured, no renin was produced into the supernatant (Fig 1) Decidua neither produced renin nor grew well, and was not sub-cultured. One culture of chorion plate grew well and was sub-cultured, but produced no renin, while a second grew poorly and produced low but significant amounts

These experiments provide the first proof that other tissues as well as the kidney can synthesize renin Both chorion and myometrium growing *in vitro* produced renin at remarkable rates In 2 days the amount of renin released into the 2 ml of culture medium totalled more than that normally present in 200 ml of plasma That this renin was synthesized and not simply a release of stored enzyme is shown by its continued production through sub-culture, and by the fact that the total amount produced was far in excess of that shown previously to be present in these tissues[12]

The different time course for the production of renin in chorion and myometrium cannot be related to different growth rates, for both grew well from the start Nor is it likely that the particular cell producing renin took longer to become established in cultures of myometrium than chorion, because both cultures seemed to produce only fibroblast-like cells The possibility that myometrium contains an enzyme inhibitor which is progressively lost during culture has been excluded (unpublished work of Skinner, Lumbers and Symonds) by finding that added renin displays the expected activity in myometrial extracts We have previously shown that human myometrium contains little renin, and so it seems more likely that the synthesis of this enzyme is weakly repressed in human myometrial cells, and that, after passage through several *in vitro* generations, this repression is lost It follows from this hypothesis that production of renin by human myometrium *in vivo* probably does not usually occur Rabbit myometrium is notably different, however, with a high renin concentration[2] and presumably in this species synthesis is not repressed[8] Such extreme differences between species are likely to be of functional significance, but the reasons are not apparent at present

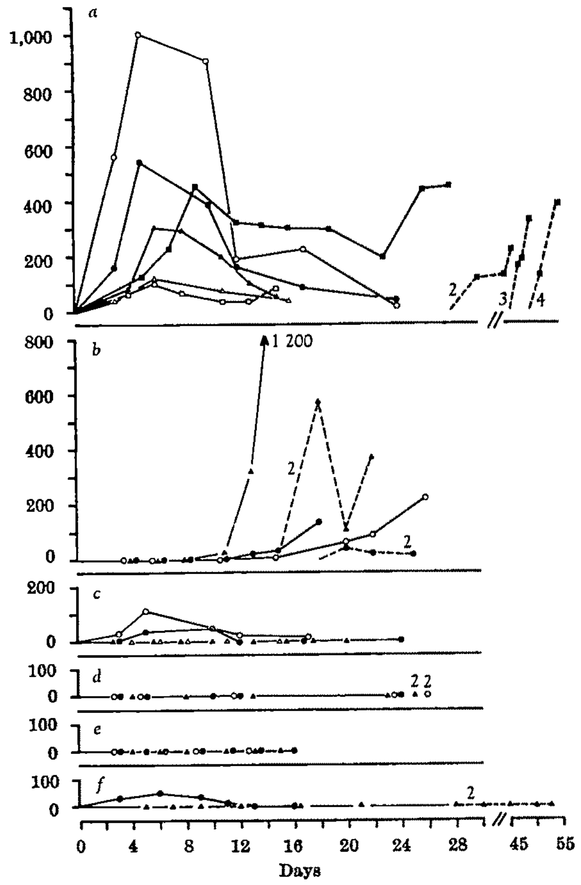

Fig 1 Renin concentration (U/ml) in selected culture media changed every second or third day Primary cultures are shown in solid lines Secondary, tertiary and quaternary cultures are shown as broken lines between symbols corresponding to the appropriate primary culture, and are numbered 2, 3 and 4, respectively *a*, Chorion, *b*, myometrium, *c*, placenta, *d*, amnion, *e*, decidua, *f*, chorion plate

No conclusion can be reached at this stage as to the specific cells involved in renin synthesis Although the growing cells looked like fibroblasts, histological investigation may reveal some heterogeneity We cannot exclude the possibility that the cells growing in culture may be decidual This seems unlikely, in view of our earlier finding that decidua contains much less renin per wet weight than chorion (unpublished) The close proximity to the amniotic sac of cells capable of synthesizing renin provides a logical explanation for the high concentrations of renin in liquor amnii

This work was supported, in part, by a grant from the National Health and Medical Research Council of Australia We thank Miss K Ormond and Mrs R Sexton for assistance with the *in vitro* cultures

Ratios between Contents of DNA, RNA and Protein in Different Micro-organisms as a Function of Maximal Growth Rate

THE growth medium determines the macromolecular composition as well as the growth rate (number of doublings per hour) of micro-organisms in the steady state of growth For a given micro-organism the ratios of RNA protein and RNA DNA are linear functions of the growth rate, whereas the ratio of DNA protein is virtually independent of the rate of growth[1–4] All these studies involved one micro-organism studied at different growth rates

We have looked for a correlation between the maximal growth rates of different micro-organisms and their contents of DNA, RNA and protein. The organisms tested included twelve bacteria, a haploid and a diploid strain of yeast and a ciliate protozoon, selected to cover a range of generation times for growth at 30° C in complex media which create optimal growth conditions for many organotrophic micro-organisms[5]

All organisms were grown in batch cultures The bacteria, except *Lactobacillus bulgaricus* and *Clostridium perfringens,* were grown aerobically in 0 8 per cent Difco broth, 0 1 per cent NH_4Cl, 0 05 per cent $MgSO_4$ $7H_2O$ and 0 5 per cent glucose *Cl perfringens* was grown anaerobically in this medium and *Lactobacillus bulgaricus* was grown aerobically in 4 per cent Elliker broth (Difco) *Saccharomyces cerevisiae* was grown aerobically in 2 per cent Bacto peptone, 0 1 per cent yeast extract and 2 per cent glucose *Tetrahymena pyriformis* was grown aerobically at 28° C in 2 per cent 'Proteose' peptone (Difco), 0 1 per cent liver extract (Wilson Laboratories) and inorganic salts as described earlier[2] Generation times of the bacteria and of the yeast were determined by measuring the increase in turbidity at 450 mμ (bacteria) and at 420 mμ (yeast). The cells were collected in the steady state of growth at an optical density (*O D*) of approximately 0 5 Growth of *Tetrahymena pyriformis* was followed by particle counts in a Coulter electronic cell counter, model *F* *Tetrahymena* was grown at 28° C, and so corrections were made for the generation time assuming a doubling of the growth rate for a 10° C increase in temperature All growth rates were calculated as the number of doublings per hour at 30° C

The chemical analysis of the cellular content of DNA, RNA and protein was carried out as follows Nucleic acids were extracted from about 100 mg wet weight of cells by treatment with 0 5 N perchloric acid at 70° C for 20 min Deoxyribose was determined by the diphenylamine procedure using dAMP as standard[6] Ribose was determined by the orcinol procedure using AMP as standard[7] The protein content in the residue was determined by the method of Lowry using bovine serum albumin (Armour) as standard[8]

The rate of protein synthesis per unit of RNA has previously been determined according to the expression protein/RNA × μ, where μ = doublings per hour (refs 1, 2 and 4) Table 1 shows the rates of protein synthesis per unit of RNA for different organisms collected from steady state growing cultures The values for the rate of protein synthesis per unit of RNA vary from 2 0 to 3 1 h^{-1} This suggests a similar efficiency of the ribosomes in protein synthesis in the organisms which we studied

Table 1 RATIOS BETWEEN DNA, RNA AND PROTEIN OF DIFFERENT MICRO-ORGANISMS GROWN IN COMPLEX MEDIA AT 30° C

Micro-organism	Generation time(h)	μ = Growth rate (doublings/h)	$\frac{\text{Protein}}{\text{RNA}}$	$\frac{\text{Protein}}{\text{RNA}} \times \mu$ (h^{-1})	$\frac{\text{RNA}}{\text{DNA}}$	$\frac{\text{RNA}}{\text{DNA}} \times \mu$ (h^{-1})
Aerobacter aerogenes	0 43	2 33	1 18	2 7	12 0	28
E coli	0 50	2 00	1 47	2 9	10 9	22
Salmonella typhimurium	0 50	2 00	1 57	3 1	9 8	20
Citrobacter freundii	0 50	2 00	1 35	2 7	10 6	21
E coli B	0 52	1 92	1 54	3 0	10 4	20
Serratia marcescens	0 52	1 92	1 35	2 6	10 2	20
Bacillus subtilis	0 58	1 72	1 41	2 4	15 0	26
Erwinia carotovora	0 68	1 47	1 67	2 5	10 9	16
Micrococcus anhaemolyticus	0 72	1 39	1 85	2 6	11 2	16
Cl perfringens	0 77	1 30	1 83	2 4	12 0	16
Pseudomonas aeruginosa	0 68	1 47	1 84	2 7	5 1	7
Lactobacillus bulgaricus	0 92	1 09	2 81	3 1	9 4	10
Saccharomyces cerevisiae (diploid) No 66	1 25	0 80	2 44	2 0	82 0	66
Saccharomyces cerevisiae (haploid) 1507–7*A*	1 50	0 67	2 98	2 0	105 0	70
Tetrahymena pyriformis GL	2 00	0 50	4 34	2 2	24 0	12

The determination of the growth rates of the micro-organisms and the chemical analysis of DNA, RNA and protein were carried out as described in the text Each value represents the mean of triplicate determinations of DNA, RNA and protein in two independently grown cultures

The ratio of DNA protein for *Escherichia coli, S typhimurium, A aerogenes* and *T pyriformis* in the steady state of growth has been shown to be almost independent of the growth rate of these organisms[1–4] The relationship is almost linear when the ratios of DNA protein for each of the organisms studied are plotted against their maximal growth rate (Fig 1) The ratio of DNA protein for *S cerevisiae* is lower than would be expected from the growth rate When, however, a haploid strain of *S cerevisiae* was compared with a diploid strain, the general trend shown in Fig 1 was confirmed The diploid strain shows a significantly higher ratio of DNA protein as well as showing faster growth

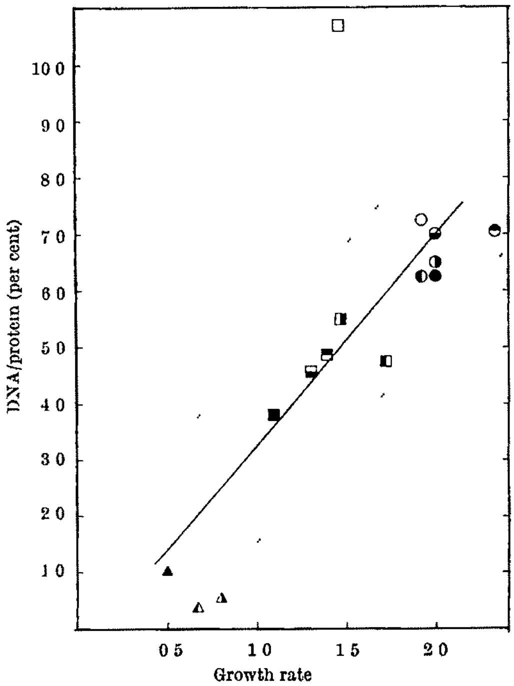

Fig 1 Ratio of DNA protein as a function of maximal growth rate for a number of micro-organisms growing at 30° C Each ratio of DNA protein represents the mean of triplicate determinations of DNA and protein contents in two independently grown cultures DNA and protein were determined as described in the text The solid line is drawn as calculated by the "estimate (regression) equation" The zone ± 1 $s_{Y\,X}$ (standard error of estimate) is shown by the dotted lines ◓, *Aerobacter aerogenes*, ●, *Escherichia coli*, ◐, *E coli B*, ◑, *Salmonella typhimurium*, ◧, *Erwinia carotovora*, ○, *Serratia marcescens*, ◒, *Citrobacter freundii*, ◧, *Bacillus subtilis*, □, *Pseudomonas aeruginosa*, ■, *Lactobacillus bulgaricus*, ⬒, *Micrococcus anhaemolyticus*, ⬓, *Cl perfringens*, ◭, *Saccharomyces cerevisiae* (haploid) 1507–7*A*, ◮, *Saccharomyces cerevisiae* (diploid) No 66, ▲, *Tetrahymena pyriformis* GL

The correlation shown in Fig 1 suggests that the amount of the DNA template can be a rate limiting factor for the flow of information from DNA to protein, that is, that the amount of DNA can be limiting for *m*RNA synthesis A high ratio of DNA protein could favour a high overall production of *m*RNA in fast growing organisms This explanation is consistent with the hypothesis that the degradation of *m*RNA is possibly correlated with the translation of *m*RNAs on the ribosomes[9–11] A fast growing organism with a high ratio of DNA protein might thus have a higher turnover of *m*RNA than a slow growing organism because of its higher content of DNA and ribosomes

A second explanation could involve the fact that ribosomes are active in the regulation of *m*RNA synthesis in bacteria[11–14] This mode of regulation, which suggests that ribosomes are needed for the detachment of *m*RNA from the DNA template, could depend on the appropriate amount of DNA per ribosome Thus the ratio of RNA DNA as well as the ratio of RNA protein could be important for a micro-organism to grow at the maximal rate

This work was supported by a grant from Carlsberg-fondet I thank Professor Hans Klenow, Professor Ole Maaløe, Dr K Overgaard-Hansen and Dr Ronald Pearlman for helpful suggestions and criticism

Evidence for an Extragranular Localization of Tyrosine Hydroxylase

GROWING interest in the intracellular localization of enzymes has led to the standardization of techniques generally used in tissue fractionation The scope and limitations of these methods have been defined already, in particular the use of marker enzymes in profiling the distribution of different particles[1]

The data concerning the intracellular localization of tyrosine hydroxylase are rather conflicting Nagatsu *et al* [2], who first isolated the enzyme, described it as particle-bound, while Udenfriend[3] has proposed that all enzymes involved in biosynthesis of catecholamine are organized into granules containing catecholamine In the brain, tyrosine hydroxylase was found to be linked to a particulate fraction[4] Stjarne and Lishajko[5], however, have shown, by incubating *in vitro* various fractions of a bovine splenic nerve homogenate, that this enzyme occurs outside the granules

This communication describes experiments dealing with the activity of tyrosine hydroxylase in various fractions of bovine adrenal medulla and in different segments of the splenic nerves of dogs

Bovine adrenal medullae were homogenized in five volumes of either 0 25 M sucrose or of 0 16 M potassium chloride with a 'Dual' homogenizer The sediment obtained after low speed (7,000g min) centrifugation was resuspended in the same volume and centrifuged again at the same speed to provide a pellet of the nuclear fraction A sample of the pooled supernatants was kept and the rest was further fractionated by centrifuging at $6 \times 10^6 g$ to obtain a large particulate fraction and a final supernatant The whole fractionation procedure was carefully carried out at 0° C

Splenic nerves were ligatured as previously described[6] Two segments of nerves were removed 48 h after operation, one above (proximal to) and another below (distal to) the ligature As with the coeliac ganglion or normal splenic nerves, they were homogenized in twenty volumes of 0 25 M sucrose

The total activity of dopamine-β-hydroxylase was assayed using tyramine as the substrate and in the presence of 'Triton X-100', as previously described[7] Tyrosine hydroxylase was assayed according to Nagatsu *et al* [2] using labelled tyrosine (New England Nuclear Corp , ^{14}C-L-Tyrosine, specific activity 300 mCi/mmole) The dopamine-β-hydroxylase was separated on Al_2O_3 columns and the radioactivity was counted in a Packard liquid scintillation spectrometer In order to eliminate interfering of large amounts of catecholamines, acid-insoluble proteins were determined according to Lowry's method[8]

Fig 1 shows the distribution patterns of tyrosine hydroxylase and dopamine-β-hydroxylase when the fractionation of adrenal medulla was carried out either in a sucrose or in a KCl medium Dopamine-β-hydroxylase provides a valuable marker to fix the position of the catecholamine granules on the distribution diagrams[10] This enzyme behaves similarly in both experimental conditions, as shown by its distribution patterns, in that more than 60 per cent of the activity is found in the large particulate fraction On the other hand, the distribution of tyrosine hydroxylase is quite different from that of dopamine-β-hydroxylase In sucrose solutions 34 per cent of the activity is found in the nuclear fraction and 41 per cent in the supernatant This bimodal distribution becomes nearly unimodal in potassium chloride solutions with values of 16 per cent and 70 per cent

The different distribution of tyrosine hydroxylase could be a result of higher adsorption of soluble proteins in sugar solutions than in ionic media Nevertheless, these experiments show clearly that, by comparing the distribution patterns of these two enzymes, it cannot be suggested that tyrosine hydroxylase is contained in the catecholamine granules Furthermore, other data concerning the latency of all the enzymes of noradrenaline biosynthesis and dealing with the uptake of various amines[11] support the view that tyrosine hydroxylase is located in an extragranular site, probably the cell sap The results listed in Table 1 lead to a similar conclusion

Thus the activity of tyrosine hydroxylase was found to decrease slightly above the proximal segment 48 h after ligation, although, for the same period, the activity of dopamine-β-hydroxylase was twenty times greater than that of the control values In contrast, both enzymatic activities decreased similarly in the distal segments It should also be noted that these activities are slightly

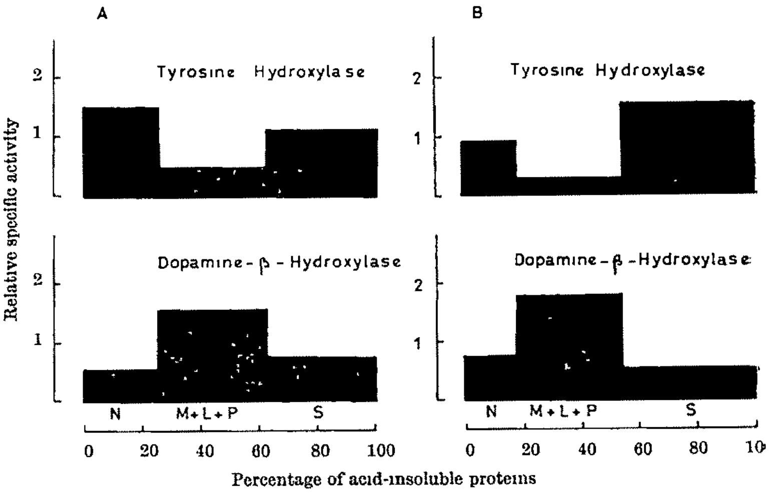

Fig 1 Distribution pattern of enzymes *A*, fractionation was performed in 0 25 M sucrose and, *B*, in 0 16 M potassium chloride Each graph represents the mean of three experiments N, Nuclear fraction, M+L+P, large particulate fraction, S, supernatant. The results are presented in the manner used by de Duve *et al* [9]

Table 1. ENZYMATIC ACTIVITY IN SPLENIC NERVES AND COELIAC GANGLIA OF DOGS

	Tyrosine hydroxylase (μmoles/g/h ± S D)	Dopamine-β-hydroxylase (μmoles/g/h ± S D)
Splenic nerve		
Control	0 39 ± 0 09 ($n=5$)	0 79 ± 0 56 ($n=5$)
Proximal part 48 h after ligation	0 21 ± 0 09 ($n=12$)	15 1 ± 6 8 ($n=5$)
Distal part 48 h after ligation	0 12 ± 0 07 ($n=12$)	0 39 ± 0 35 ($n=5$)
Coeliac ganglion		
Control	0 56 ± 0 24 ($n=16$)	1 49 ± 0 36 ($n=11$)

higher for the coeliac ganglion than for the splenic nerves

If tyrosine hydroxylase were associated with granules containing catecholamine and dopamine-β-hydroxylase, a similar accumulation above a constriction of the sympathetic nerves, as proved for dopamine-β-hydroxylase and previously for noradrenaline[6], should be expected for tyrosine hydroxylase The fact that tyrosine hydroxylase does not increase in the proximal part after ligation points to an extragranular localization of the enzyme This new approach confirms the previous data of Stjarne and Lishajko[5]

Because these observations show that tyrosine hydroxylase in the adrenal medulla and sympathetic nerves is independent from the granules containing catecholamine, the first step of catecholamine biosynthesis, as well as the second one[11], occurs outside these granules

BIOLOGY

Germination of Caryophyllaceae at Low Temperatures in relation to Geographical Distribution

SEED germination is one of many factors which determine whether a particular species is able to maintain itself in a given locality This must occur at a season which will allow the subsequent development of the plant and the production of flowers and viable seed There have been many reports of the mechanisms which regulate the time of germination based on requirements for a period of after-ripening, temperature conditions, light or mechanical injury Yet few studies have been made on the relation between germination patterns and natural distributions of different species This work was done with a group of species of Caryophyllaceae distributed in different localities throughout Europe, in an attempt to determine features of the germination response which could be correlated with climatic conditions

Ripe seed was collected from plants growing in the Royal Botanic Gardens, Kew, and stored over calcium chloride at 18° to 22° C, until required for tests. Tests were done in incubators at 2° C, or on a specially designed thermogradient bar set to provide continuously variable temperatures from about 5° to about 18° C Temperatures on the bar were monitored through thermo-couples and could be defined at any point throughout the bar's length to within ±0 5° C The seeds were sown on a basic medium consisting of the standard Long Ashton nutrient solution[1], used at half-strength and stabilized with 1 per cent agar They were taken as having germinated as soon as the radicle was visible Records were made either at convenient intervals in the incubators at 2° C, or daily on the thermo-gradient bars

Fig 1 illustrates the way in which the rate of germination at 2° C varied between different species grouped according to their broad geographical distributions These groupings are approximate, for the occurrence of some of these species as weeds makes their natural distribution hard to define The geographical definitions used, however, are so broad and the difference between the groups so distinct that they overwhelm any differences of opinion on the precise ranges of the species concerned

There were wide variations in the rates of germination and the limits for reaching the 50 per cent level lay between 19 days for *Agrostemma githago* and nearly 190 days for *Silene alba* All the species from the Mediterranean germinated rapidly at this low temperature, whereas none of the species from northern Europe reached the 50 per cent level in less than 100 days; central European species occupied intermediate positions

Germination rates of a selection of species were recorded at temperatures between 5° C and 18° C on the thermo-gradient bar, and graphs were prepared from which the number of days required for each species to reach 50 per cent germination at different temperatures could be calculated. The results (Fig 2) showed that the rates of germination varied from one species to another, and that the speed of germination could be related to the geographical range over the whole temperature range tested There was no straight line relationship between germination rate and temperature, and the exponential curves obtained showed a rapidly increasing steepness as the temperatures fell. There was evidence that the temperature range over which the curves tended to the vertical was correlated with geographical range, occurring at increasingly higher temperatures as the distribution of the species moved north *Kohlrauschia prolifera*, classed as a central European species, was a possible exception to these generalizations appearing in Fig 2 in association with the Mediterranean species *Agrostemma githago* and *Silene nocturna*

Supplementary experiments on these species have shown that most of them have a short period of relative dormancy, after the fully mature seed is shed, during which they fail to germinate at temperatures above about 20° C Germination at lower temperatures is normally unaffected by after-ripening requirements, and, because the seed in these tests had been kept in store for several months and germinated freely to 90 per cent or more at temperatures between 10° C and 18° C, it is unlikely that the results obtained were distorted by any unsatisfied after-ripening requirements of the seed It seems probable that the measurements represent the capacity of each species to grow at low temperatures, and reflect a phenomenon similar to that reported by Cooper[2] for ecotypes of *Lolium perenne* collected from varying geographical locations Cooper found that *Lolium perenne* from northern or colder areas stopped growth at higher temperatures than those from regions with milder winters such as the Mediterranean

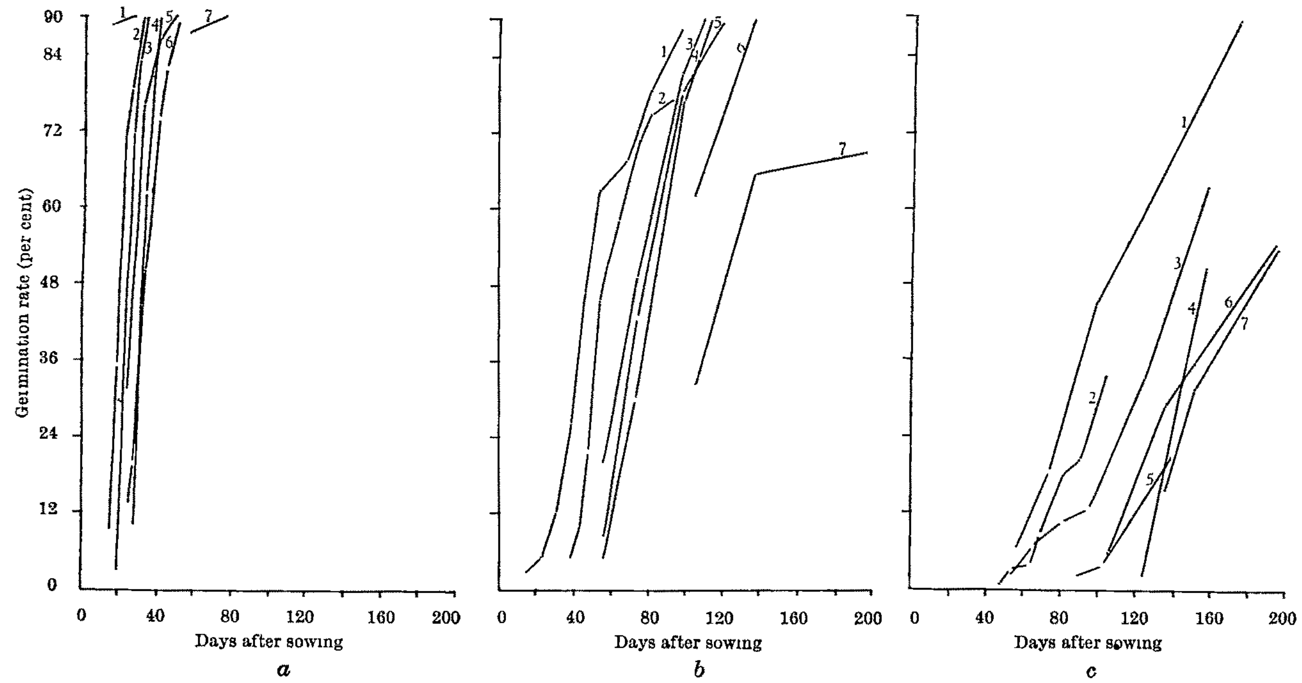

Fig 1 Rate of germination at 2° C of species of Caryophyllaceae from *a*, Mediterranean 1, *Agrostemma githago* L (1966), 2, *Agrostemma githago* L , 3, *Silene chloraefolia* Sm , 4, *S nocturna* L , 5 *S colorata Poir*, 6, *S rubella* L , 7, *S nocturna* (1966) *b*, Southern and central Europe 1, *Vaccaria pyramidata* Medicus, 2, *Silene gallica* L , 3, *Silene italica* (L) Pers , 4, *Lychnis flos-jovis* (L) Desr 5, *Silene compacta* Fischer, 6, *S italica* (L) Pers (1966), 7, *Kohlrauschia prolifera* (L) Kunth *c*, Northern and north-west Europe 1 *Silene dioica* (L) Clairu, 2, *Silene alba* (Mill) E H L Krause, 3, *Silene maritima* With , 4, *Dianthus deltoides* L , 5, *Silene cucubalus* Wibel, 6, *Lychnis viscaria* L , 7, *Silene alba* (1966) All seed from 1967 harvest unless otherwise marked

The exponential relationship between germination rate and temperature shows that, with these species, straight line extrapolations of the kind made by Went[3] to determine minimum temperatures for germination would be quite inadmissible, and that in fact no determinable minimum (above 2° C) exists Each of these species was capable of germination at all temperatures down to 2° C, although germination was very slow in some of the species from northern Europe at the low temperatures

No work has yet been done to relate the results to climatic situations in the localities from which the species come They may be similar in some respects to the results reported by Went and co-workers[4,5], on temperature effects on the germination of winter and summer annuals in California, to the extent that Mediterranean species with their capacity for germination at low temperatures seem to be adapted for germination in late autumn and winter whereas the species from northern Europe in which germination is very slow in soil temperatures around 9° C would not usually germinate to any extent in Britain after early September

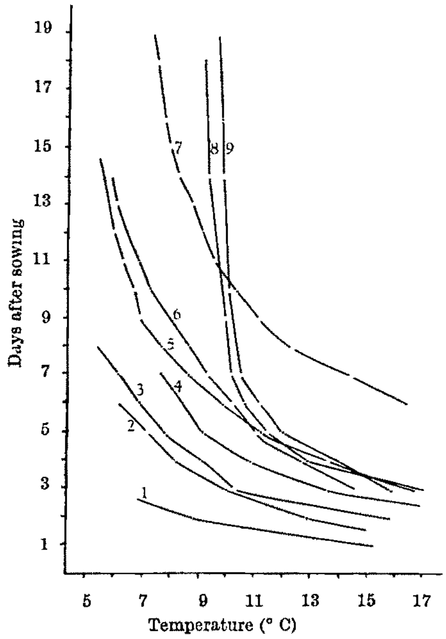

Fig 2 Temperatures at which various species of Caryophyllaceae attained 50 per cent germination rate on successive days after sowing 1, *Agrostemma githago* L , 2, *Kohlrauschia prolifera* (L) Kunth, 3, *Silene nocturna* L , 4, *Silene italica* (L) Pers , 5, *Lychnis flos-jovis* (L) Desr , 6, *Silene noctiflora* L , 7 *Lychnis viscaria* L , 8, *Silene cucubalis* Wibel, 9, *Silene dioica* (L) Clairu

The results reported here are based on relatively few species, but the correlations between distribution and germination are marked They provide no indication of the amount of variability within a particular species, however, and experiments are now in progress to determine to what extent germination behaviour of a species may show modifications according to the location of individual populations within its general range

Saprolegnia parasitica Coker in Estuaries

DICK's interesting comments[1] on our communication[2] point to the need for further work on this complex topic—a fact of which we are not unaware Indeed, our communication was intended solely as an interim report on work in progress in order to show that too facile dismissal of fungal involvement in previously reported work was premature

We did not set out to answer "whether *S parasitica* is a fresh-water fungus or a fungus capable of growing and sporing in both fresh-water and estuarine environments" We merely recorded two facts (*a*) that *Saprolegnia* has been isolated in a number of cases from fish that we can prove to be freshly arrived in an estuary, and (*b*) that *S parasitica* can grow in saline conditions

At this stage of the investigation, these are facts important enough to warrant recording and are not vitiated by Dick's comments For *Saprolegnia* to be involved at all in estuarine conditions it is not essential, as Dick states, to find out whether the fungus is capable of sporulating and so on equally well in both fresh-water and estuarine conditions (Q1–6), however desirable it may be to have further evidence along these lines We do not imply that the estuary is the sole locus for infection, and indeed believe that it is much more likely that *Saprolegnia* is more active in fresh water

Finally, we state that "the apparent correlation between the spread of the fungus in ulcerative dermal necrosis and water temperature merits investigation" This is a general observation and nowhere do we quote "temperature data for asexual sporulation" as Dick states

Resistance of Rainbow Trout to Ulcerative Dermal Necrosis

THE susceptibility of rainbow trout to ulcerative dermal necrosis[1], an infectious disease of some salmonids, has become a matter of importance to fish farmers We have shown that the aetiological agent of ulcerative dermal necrosis is filterable[2] although some workers have suggested that specific bacteria[3,4] or fungi[5] may be the primary pathogens Preliminary experiments indicated that rainbow trout exposed to a salmon affected by ulcerative dermal necrosis did not show symptoms of the disease whereas a healthy salmon in the same tank as the trout did The siphoning technique successfully used to reproduce ulcerative dermal necrosis in salmon[2] was adapted to the experiments described here, which were designed to ascertain the susceptibility of rainbow trout to the disease Further experiments, also described, were carried out to show whether rainbow trout can act as symptomless carriers

In experiment *A*, ten mature hatchery-reared rainbow trout obtained from the Inland Fisheries Trust farm at Roscrea were divided into two equal groups One group was kept as a control and the other was placed in a tank with a salmon obtained from the Boyne, a river free from ulcerative dermal necrosis Water was siphoned into the tank containing the trout and salmon from a tank containing a salmon obtained during a natural outbreak, and showing clinical signs of ulcerative dermal necrosis[1] Both tanks (and all tanks used in these experiments) were disinfected with a chlorine solution before use

The mean water temperature was 10 8° C, range 7 5–13 0° C On the fifteenth day of the experiment, the Boyne salmon died showing lesions of ulcerative dermal necrosis The five trout in the tank with the salmon showed no lesions, and they and the controls remained clinically healthy until the end of the series of experiments, more than 4 months later

In experiment *B*, the five rainbow trout exposed to infection in experiment *A* were placed in one disinfected tank and a healthy salmon from the Boyne was placed in another Water was siphoned from the tank containing the trout to that containing the salmon The mean water temperature was 7 2° C, range 5 0–8 0° C On the forty-seventh day of the experiment the salmon was in excellent health and showed no signs of ulcerative dermal necrosis The usual incubation period of the disease is 7–17 days[2]

In experiment *C*, the salmon used in experiment *B* was placed in a disinfected tank, and water was siphoned to it from a tank containing a salmon affected in a natural outbreak of ulcerative dermal necrosis The mean water temperature was 6 3° C, range 3 0–10 0° C The recipient salmon died showing lesions of ulcerative dermal necrosis

The results of experiment *A* confirmed previous findings that rainbow trout do not show clinical signs of ulcerative dermal necrosis Trout do not act as symptomless carriers of the disease, for the salmon which had been exposed to possible infection from the trout in experiment *B* was in fact susceptible, as shown in experiment *C*, so the result of experiment *B* was obtained because the trout were not infective

Imprinting: Drug-produced Isolation and the Sensitive Period

IMPRINTING as a phenomenon in early behavioural development owes much of its importance to the fact that it occurs only during a limited period of an animal's life Although there is some disagreement as to the exact nature and duration of this sensitive period, there is general agreement that such a period exists

Because of its importance in distinguishing imprinting from other forms of stimulus-response association, the sensitive period has been the subject of considerable theoretical interest This interest in turn has centred on the factors which influence the length and offset of the period Bateson[1] has recently reviewed empirical studies of the role of these factors and has concluded that the imprinting response will usually continue to occur to a particular stimulus unless the bird concerned has had an opportunity to develop a preference for something else This is, of course, equivalent to saying that imprinting as a process is inevitable and it will happen to either a class of stimuli in the bird's regular environment, or to a stimulus presented in an experimental imprinting situation.

I have developed this argument by assuming that the tendency to imprint on experimental objects declines as a result of the bird imprinting on some stimuli in its housing environment If this imprinting on the general environment is made less effective by procedures which are known to make experimental imprinting less effective, then the time during which the bird will remain responsive to test objects will be prolonged While it would be desirable to test directly the strength of attachment to aspects

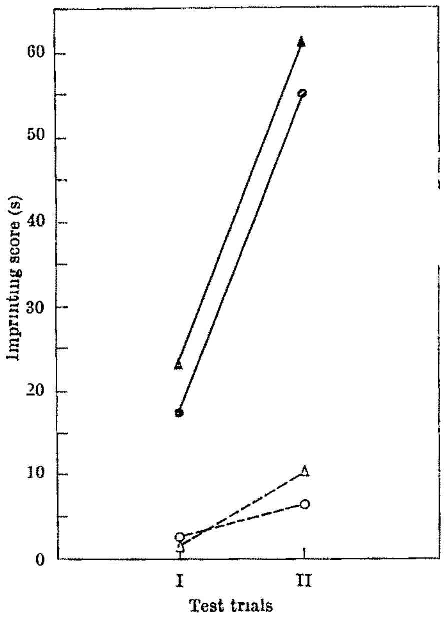

Fig 1 Imprinting scores for two drug groups and two control groups on the fourth day (test trial I) and the fifth day (test trial II) of life The imprinting score is the mean time spent within 12 in of the imprinting stimulus during 5 min Drug ●, 10 mg/kg, and ▲, 15 mg/kg Control ○, 10 mg/kg, and △, 15 mg/kg

of the housing environment, it is not possible to do so because of the presence of confounding factors such as food and warmth

A method of making imprinting on the general environment less effective without confounding stimulus characteristics and experience is suggested by an experimental study reported by John Bradford and myself to the Eastern Psychological Association in April 1966 The results of that study—on the effects of sodium pentobarbital on the development of the approach response in the domestic chick—showed that birds injected with a small dose of sodium pentobarbital (7 mg/kg) 15 min before imprinting training trials did not develop the associations necessary to produce approach behaviour when the imprinting stimulus was presented later It follows from this result, and from the foregoing line of argument, that newly hatched chicks reared under the influence of small doses of sodium pentobarbital would not imprint strongly on their environments and would therefore continue to be more responsive to experimentally introduced stimuli when the drug is withdrawn

This proposal was tested using forty-eight White Rock × Cornish chicks, which were removed from the incubator 2 h after hatching and placed in individual compartments in a warm air brooder Immediately after this the chicks were weighed and injected intraperitoneally with either 10 mg/kg or 15 mg/kg of sodium pentobarbital or equivalent volumes of control solution Thus there were two drug groups and two control groups The chicks were injected again 4 h later and again at approximately 10 a m , 2 p m and 6 p m on the following 2 days On the fourth day the subjects were injected at 10 a m and given imprinting test procedures at 4 p m On the fifth day the subjects were again tested in the imprinting situation

The imprinting procedure was a modification of that used by James[2] and consisted of placing the bird in a 1 ft × 1 ft × 6 ft alley with the stimulus, consisting of a flashing light and intermittent sound, on at one end When the bird approached within 12 in of the stimulus and when 60 s had elapsed, the stimulus was switched to the other end These 60 s trials were repeated five times and resulted in a procedure functionally equivalent to the bird following a stimulus The imprinting score was time spent within 1 ft of the stimulus during the 5 min period

As can be seen in Fig 1, the results were clear Both groups which were kept partially isolated and treated with the drug showed much higher responsiveness to the imprinting test stimuli than their corresponding control groups The experimental groups also showed a greater increase in imprinting scores from the first test day to the second test day than did the controls The differences were shown to be significant by analysis of variance ($P<0\ 01$) There were no significant differences between the two treated groups or between the two control groups

These results lend strong support to the notion that the offset of the critical period for experimental imprinting is a result of the birds imprinting on or forming associations with stimuli in their general environment Furthermore, because the birds were pharmacologically isolated for only a part of each 24 h period, there is the implication that imprinting on general environmental stimuli is not set in absolute opposition to imprinting on a test stimulus Rather, a partial reduction in imprinting on the general environment will result in a corresponding increase in the time that the bird remains sensitive to experimentally produced imprinting test stimuli

Dispersal of Larvae by Equatorial Ocean Currents and its Importance to the Zoogeography of Shoal-water Tropical Species

PLANKTONIC larvae are dispersal stages which make it possible for marine species to breach faunal barriers and to colonize new regions The occurrence of trans-oceanic dispersal by larvae of the shoal-water tropical benthos can be deduced if the actual distribution of such larvae is known relative to the principal ocean currents likely to transport them

Taken as a whole, the North Atlantic surface circulation may be regarded as an enormous clockwise gyre The Gulf Stream continuing as the North Atlantic Drift passes eastward toward the European continent The Canary Current joins the North Equatorial Current which passes westward from the coast of Africa to the shores of South America In the southern hemisphere, the Atlantic forms a similar gyre, but rotates counterclockwise Circulation in the North and South Atlantic is actually much more complex than this simplification, which is adequate for the purpose here

Within the equatorial region the North Equatorial Current is separated from the South Equatorial Current by a rather weakly developed Equatorial Countercurrent moving eastward Unlike the currents on either side of it, the countercurrent moves a relatively small volume of water, and usually extends only part of the way across the western Atlantic Monthly charts of the North and South Atlantic surface circulation constructed by Schumacher and the US Hydrographic Office[1-3] show the Equatorial Countercurrent to be diffuse and seasonal in occurrence The surface currents of the Atlantic described here are common knowledge, and may be found illustrated in any good atlas

Consider now the distribution on the ocean surface of larvae that belong to tropical benthic species The biological data are from more than 600 plankton samples taken throughout the North and Equatorial Atlantic Larvae from the chief invertebrate phyla, including the Coelenterata, Echinodermata, Arthropoda, Annelida and Mollusca[4], are found in the surface waters of the open sea A diversity of taxa are known from each of these phyla For example, among the gastropods alone, at least nine families are represented, including the Cymatiidae, Triphoridae, Architectonicidae, Ovulidae, Cypraeidae, Tonnidae, Thaidae, Magilidae and Naticidae[5] About 79 per cent of all plankton samples taken from the North Atlantic contain veliger larvae of benthic gastropods, and it is certain that many additional families will be represented when the material is further studied

One example among the gastropods can be examined in more detail Veliger larvae of the genus *Philippia*, belonging to the prosobranch gastropod family Architectonicidae, are frequently found in the surface waters of the tropical North and South Atlantic Several species are represented, but one common form is believed to be *Philippia krebsii* Morch[6]

As a reproducing adult, this species is restricted entirely to tropical and subtropical regions Its vertical distribution, however, extends from 7 to 205 m (ref 6) Such a range in depth means that the species frequently must live at temperatures well below 20° C, for although tropical surface waters often exceed 27° C, at 150 to 200 m the water temperature at the bottom may be as low as 12°–15° C It is concluded from this that *Philippia krebsii* must be eurythermal or at least that the adult of the species lives at wider ranges of temperatures than might at first be expected from its tropical distribution

The larvae of *Philippia krebsii* are characteristic of tropical gastropod veligers found in the open sea The protoconch or larval shell is thin and not heavily calcified, the velum has large lobes used in swimming and feeding The vivid colours of the larvae can only be seen in living specimens at sea When the distribution of Architectonicid larvae is examined, particularly that of *Philippia krebsii*, the veligers are seen to be distributed along the entire periphery of the North Atlantic gyre The larvae are clearly also eurythermal, sometimes occurring in water much colder than 20° C in the North Atlantic Drift while more commonly at 27° C in the surface waters at the equator (Fig 1)

If the larvae can delay metamorphosis long enough, then the North Atlantic can be regarded as a giant roundabout, and the riders, that is the larvae, if lucky, can jump off at any point along the way There is already evidence, from holding larvae captured at sea, to suggest that a considerable number of tropical gastropod species have veligers that remain planktonic for a long time (for example, *Cymatium parthenopeum*[7]) Furthermore, it is known from experiments that settlement of some gastropod veligers can be delayed in the absence of an environment where post-larval survival is possible[8–10]

There are many tropical species that are shoal stenothermal warm-water forms, and yet are amphi-Atlantic in their distribution Such species will not readily survive the colder temperatures of 20° C and less that are

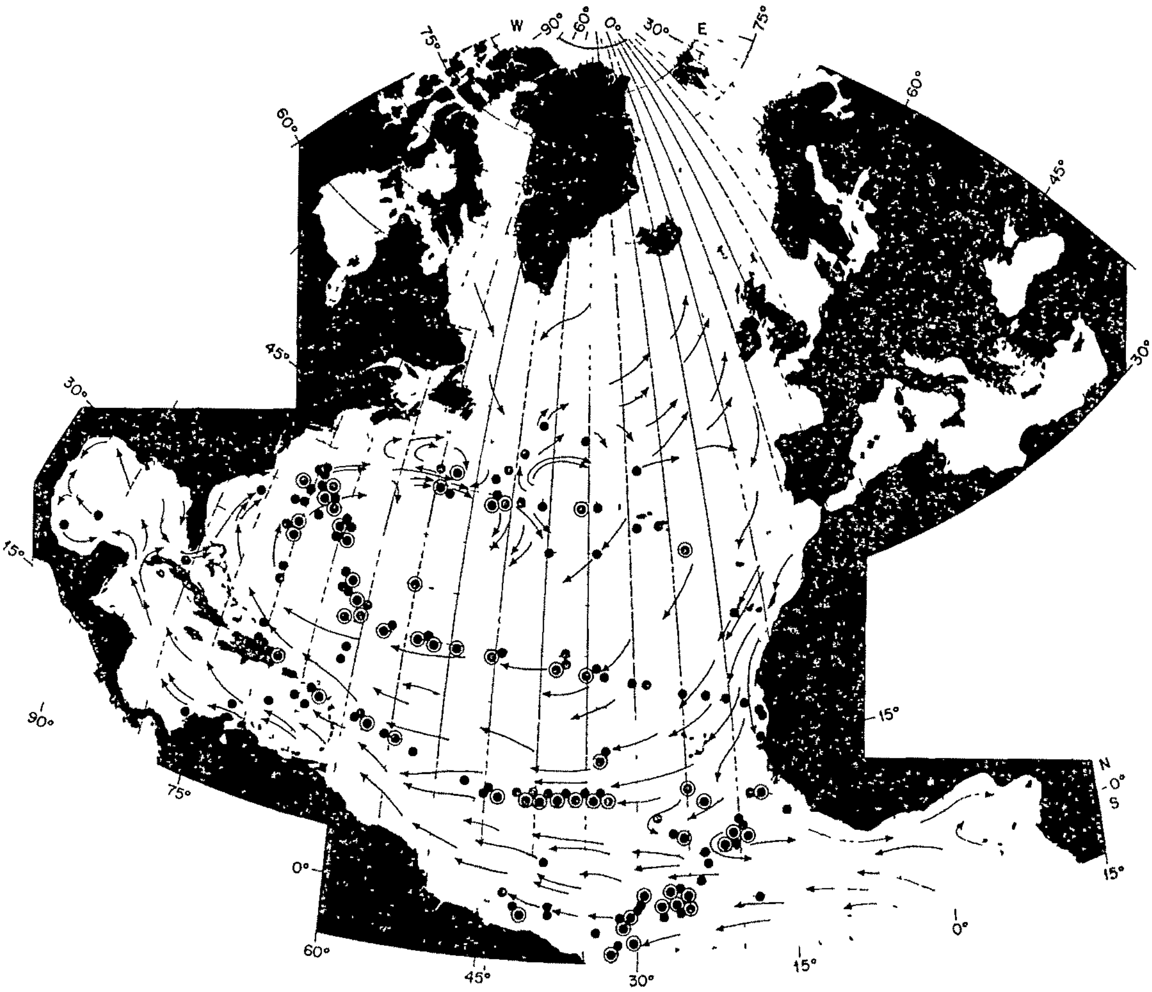

Fig. 1 Distribution of veliger larvae of the gastropod family Architectonicidae Adults belonging to this family are distributed throughout the tropics Circled stations include *Philippia krebsii* (Morch, 1875)

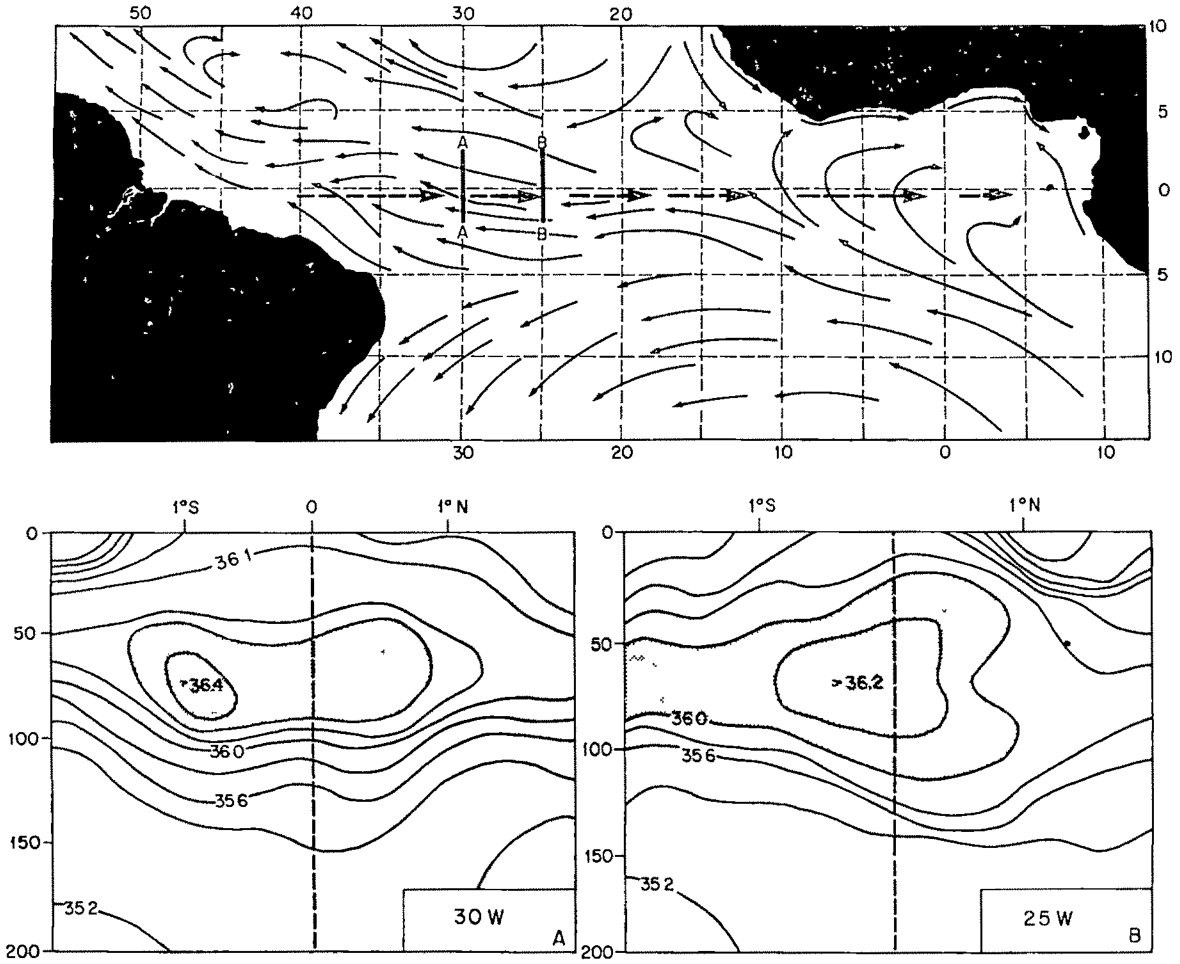

Fig 2 The Equatorial Undercurrent is a sub-surface core of saline water moving in an easterly direction at a depth of from approximately 60 to 90 m It flows directly under the equator between Brazil and the island of São Tomé in the Gulf of Guinea[12], and is shown in vertical cross-sections The more saline water of the undercurrent is stippled in the cross-sections Plankton samples were taken from this portion of the water column Vertical salinity sections modified after Khanaychenko *et al* [13]

frequently encountered in the North Atlantic Drift Examples of stenothermal forms are found among the Zoanthid corals and a wide variety of other organisms The question now arises how Zoanthid corals, restricted entirely to the tropics, can possibly be dispersed from the western to the eastern Atlantic, for although the transport of Semper's larvae from the coast of Africa to South America is readily explained by drift along the North or South Equatorial Current, it is not immediately obvious how transport in the opposite direction can occur Certainly the Equatorial Countercurrent does not provide a very likely means for easterly dispersal

The answer to this problem was unwittingly provided in 1886 by the hydrographer Buchanan when he described to the Royal Geographical Society "the very remarkable undercurrent setting in a south-easterly direction with a velocity of over a mile per hour"[11] This current was found directly under the equator as far as Buchanan was able to trace it It is remarkable that this information has been rediscovered only recently in an international oceanographic expedition of the tropical Atlantic commonly referred to as "Equalant" The current described by Buchanan, now generally known as the Equatorial Undercurrent, is an easterly subsurface flow at a depth of between 60 and 90 m It is evident in salinity profiles as a saline core of water (Fig 2) The maximum velocity of the current varies from 1 to 5 km/h and averages perhaps 2 km/h (ref 13) Most important is the fact that the water temperature in its core is warm, exceeding 25° C at its centre (Fig 3) Thus it might readily be supposed that the Equatorial Undercurrent could serve as an important agent for zoogeographical dispersal

Semper's larvae of the Zoanthid coral are not particularly striking, and their coelenterate affinities are not

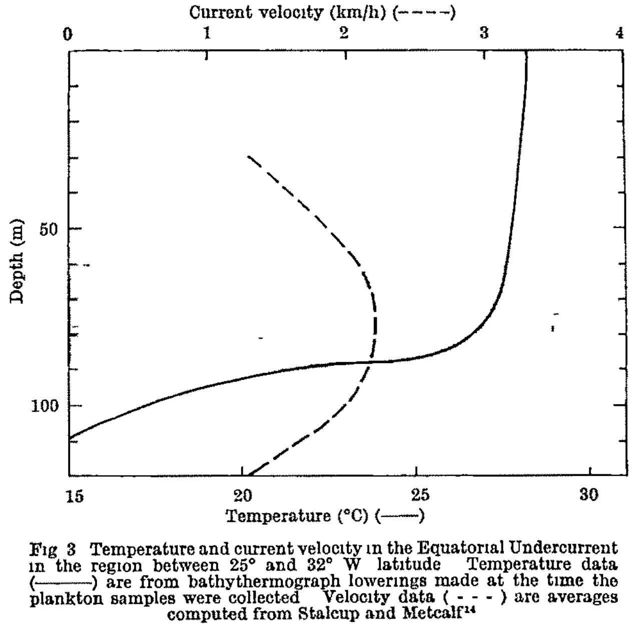

Fig 3 Temperature and current velocity in the Equatorial Undercurrent in the region between 25° and 32° W latitude Temperature data (——) are from bathythermograph lowerings made at the time the plankton samples were collected Velocity data (- - -) are averages computed from Stalcup and Metcalf[14]

immediately obvious When such larvae are sectioned, however, this affinity becomes evident from the presence of septa The distribution of the Semper's larvae from one species will serve to demonstrate the importance of the undercurrent

Throughout the tropical Atlantic there is a larval form, probably belonging to the genus *Palythoa*, which is entirely restricted to water at 23° C or more The species has rarely been found in the Gulf Stream at 36° north latitude but it is very prevalent throughout the equatorial Atlantic (Fig 4) But does it occur in the undercurrent, and can this account for its dispersal from South America to Africa ? Closing nets can be used to take samples at any given depth interval Net tows taken in the Equatorial Undercurrent, that is, between 50 and 100 m depth, show that Semper's larvae of this species regularly occur in the eastwardly moving undercurrent Hence the larvae of *Palythoa* can drift westward on the North or South Equatorial Current and eastward in the Equatorial Undercurrent While there are a great variety of other shoal water benthic larvae found in the undercurrent, interestingly enough *Philippia krebsii* is seldom among these, for it is almost entirely restricted to surface waters (0–50 m)

It is now apparent that there are two means by which larvae can be transported from east to west across the Atlantic The first is by way of the North Atlantic Drift and can only be accomplished by eurythermal forms, the second is by means of the Equatorial Undercurrent and is the only means available to stenothermal tropical species

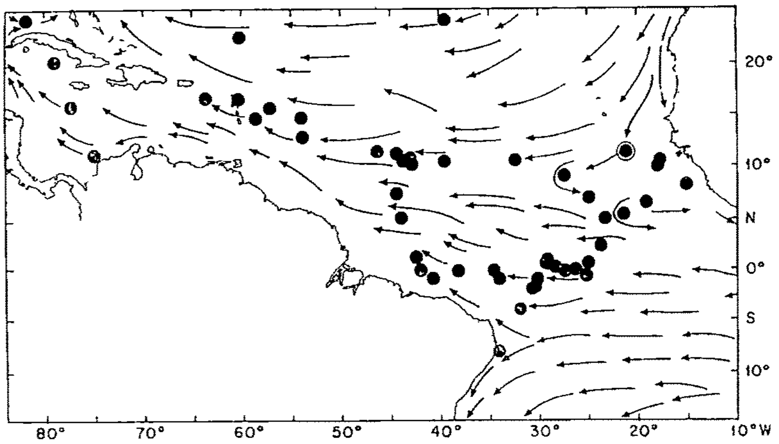

Fig 4 Distribution of Semper's larvae from a Zoanthid coral taken in plankton tows throughout the equatorial Atlantic

Direct evidence from their distribution in the open sea shows that larvae are commonly dispersed over long distances by ocean currents The examples that I have given are only illustrative of a large volume of unpublished data There is no doubt that the exchange of species can occur across the Atlantic in either direction between Africa and South America The dispersal of larvae over long distances by ocean currents offers one important explanation for the amphi-Atlantic distribution of tropical shoal-water benthic species

This research was supported by grants from the US National Science Foundation I thank Mrs Janet Moller and the officers and crew of the research vessel Atlantis II for their help

Relation between DDT in Diets of Laying Birds and Viability of their Eggs

Concern at the presence of organo-chlorine insecticides in birds' eggs has stimulated attempts to relate concentrations of toxicants in eggs to hatchability[1] We have tried to relate the ingestion of DDT by adult birds to the viability of their eggs Initially we carried out a pilot study similar to that of Cross *et al* [2] and followed this with the study described here, in which diets containing 200 p p m of DDT were fed after the start of laying to caged Japanese quail (*Coturnix c japonica*) Eggs were set at weekly intervals before and after the start of feeding of DDT and the hatchability of the eggs and survival of chicks were compared with those of a control group The concentration of DDT in the treated diet is expressed as the amount of the (*pp*) isomer contained in a commercial wettable powder containing 35 per cent (*pp*) and 10 per cent (*op*) isomers On this basis, the mean weight of *pp* DDT consumed per bird per week was estimated at 28 mg for the first week and 22 mg for the second.

Table 1 shows numbers of chicks hatched from fertile eggs, set at weekly intervals, from both groups Chi square tests show no significant changes in hatchability in either the treated or control group during the test, moreover, the hatchability of the batch of eggs collected during the second week after the start of feeding DDT showed no significant difference from the control batch We have, however, been aware of the desirability of measuring mortality in chicks for several days after hatching[3] In the present experiment, deaths among all chicks were recorded for 7 days after hatching of the first chick Approximately 79 per cent of all deaths of chicks occurred within 3 days of hatching Clear signs of DDT poisoning—strong tremors and loss of balance followed by collapse—were observed in both batches of chicks from treated parents Table 2 shows the total deaths among chicks from weekly settings A chi square test shows highly significant heterogeneity ($P = 0\ 001$) in mortality among batches of chicks from the treated group and this is largely the result of the high mortality among chicks obtained from eggs laid in the second week of consumption of food to which DDT had been added Heterogeneity in mortality among batches of chicks from the control group is not significant at the level $P = 0\ 05$

Table 1 NUMBERS OF CHICKS HATCHED FROM FERTILE EGGS

	Treated group			Control group		
Period (days)	Diet of parents	No of eggs set	No of chicks hatched	Diet of parents	No of eggs set	No of chicks hatched
1–7	Normal food only	125	74 (59%)	Normal food only	119	72 (61%)
8–14	200 p p m DDT	177	116 (66%)	,, ,, ,,	148	107 (72%)
14–21	200 ,, ,,	156	107 (69%)	,, ,, ,,	139	107 (77%)

Table 2 MORTALITY OF CHICKS DURING THE FIRST WEEK AFTER HATCHING

	Treated group			Control group		
Period (days)	Diets of parents	Nos of chicks* Hatched	Nos of chicks* Died	Diets of parents	Nos of chicks Hatched	Nos of chicks Died
1–7	Normal food only	58	10 (17%)	Normal food only	62	16 (26%)
8–14	200 p p m DDT	100	19 (19%)	,, ,, ,,	105	22 (21%)
14–21	200 ,, ,,	103	64 (62%)	,, ,, ,,	107	13 (12%)

* Chicks hatched later than 2 days after the start of hatching were discarded, as were all those which were deformed or died in the incubator before drying

We conclude that it is possible for eggs to carry amounts of DDT, or its metabolites, large enough to cause high mortality among chicks hatched from them without substantially affecting their hatchability It is also clear that the situation in which newly hatched chicks rely for some days on stored yolk for nutrition, which Koeman *et al* [3] suggested to represent a hazard to birds contaminated with dieldrin, also applies potentially to DDT

We thank E N Wright for helpful discussions, A Taylor for analysing a sample of DDT and Miss G M Parrott who carried out much of the practical work

Relationships among Functional Properties of Californian Grassland

THE communication by McNaughton[1] provides an example of the problems which arise when a quantitative approach is made to a subject such as ecology

McNaughton attaches significance to a correlation between a dominance index and number of species but, as defined, his parameters are not independent. If a sample contains only four species, the two species contributing the greatest (most important) proportion to the standing crop must exceed 50 per cent—otherwise all species contribute equally For the range of species number studied, this minimum value varies from 33 3 per cent for six species to 12 5 per cent for sixteen species Percentage contribution is not logically independent of species number

Species number (richness)[1] is not usually equated with diversity as normally defined; McIntosh[2] has examined the parameters species number, dominance and number of individuals in relation to indices of diversity These indices take into account both species number and "overall dominance" or equitability—that is, the distribution of individuals among the species The questions to be asked about the relationship between species number and dominance should perhaps be rephrased as three interrelated questions (*a*) What combinations of species number and abundance occur in the field ? (*b*) Do all possible combinations of diversity for a given species number and abundance (standing crop or number of individuals) occur in the field ? (*c*) Does the range of single species dominance observed in the field correspond with the possible range for the same number of species and the same abundance ?

Definitions of the terms "diversity" and "dominance" are needed before these questions can have a precise meaning McIntosh[2] has reviewed the definition of diversity, dominance can be defined as the abundance of the species which has the greatest observed abundance The limits of this value when abundance is measured as number of individuals are

$$\text{Dominance maximum} = N - S + 1$$

$$\text{minimum} = \frac{N}{S} \text{ when } \frac{N}{S} \text{ is an integer}$$

$$\text{or} = \frac{N}{S} + 1$$

where N is the number of individuals and S is the number of species.

When standing crop is used as a measure of abundance, it is not possible to define the maximum possible contribution of a species The contribution of the most abundant single species can, however, be compared with that expected with maximum diversity (minimal dominance), that is, when all species contribute equally

A dominance index D can be used

$$D = \frac{\dfrac{X\,S}{C} - 1}{S - 1} \text{ for } S \geqslant 2$$

where C is the standing crop and X is the contribution of species X to the standing crop $D = 0$ at maximum diversity, $D \rightarrow 1\ 0$ as dominance increases D is not independent of S, as $S \rightarrow \infty$, $D \rightarrow \frac{X}{C}$ (compare McNaughton[1]), when S is small, the percentage contribution must be greater to obtain an equivalent value of D

D cannot equal 1 0, but it would be of considerable interest to know how closely observed values approach this figure The size of individuals of other species present in the community will influence this, which suggests that for a given species number the community with the greatest range in size of species will have the larger possible dominance All hypotheses of this type, however, depend on an adequate definition of the term "community", which is at present lacking

McIntosh[2] quotes Gerard[3] " Before measurements can be meaningful they must be directed to the right things and even in science, finding these right things is the major achievement, entitation is more important than quantitation", and adds "Herein lies a major difficulty of ecology". More adequate definitions are necessary before McNaughton's suggestions regarding the relationships between the functional properties, species number and dominance, and between productivity and dominance can profitably be examined

I thank D Machin, P Greig-Smith and E R B Oxley for helpful discussion and comments

Artificial Reconstruction of a Species of Fern, *Asplenium adulterinum*

AMONG the flowering plants there is a limited number of records of artificial synthesis of a natural polyploid species Of these, the first and most familiar example is *Galeopsis tetrahit*[1] The example described here, however, is the first complete synthesis of a natural species of pteridophyte

The fern *Asplenium adulterinum* Milde has a wide but extremely intermittent distribution in Central Europe and Scandinavia It is virtually restricted to serpentine and other ultrabasic rocks In morphology, it is intermediate between *A trichomanes* L and *A viride* Hudson As its name suggests, its status has been widely disputed in the past, but it has been generally accepted for many years as a genuine and distinct species All examples of *A adulterinum* which I have investigated cytogenetically, whether from localities in Austria, Norway, Switzerland or elsewhere, have proved to be tetraploid, with $n=72$ chromosomes, and to reproduce sexually All chromosome counts of this species recorded by others[2-4] are likewise tetraploid

Hybrids have been synthesized between *Asplenium adulterinum* and the two diploids which are believed to be its parents, *A viride* and *A trichomanes* ssp *trichomanes* These hybrids are triploid, and include thirty-six bivalents and thirty-six univalents at meiosis[5] I have synthesized hybrids between *A adulterinum* and two other tetraploid European species of *Asplenium*, namely, *A majoricum* Litard and *A lepidum* C Presl These hybrids, themselves tetraploid, both show uniformly complete failure of chromosome pairing in meiosis, 144 univalents being present Such a result indicates an origin by allopolyploidy for *A adulterinum* (and, incidentally, also for both *A majoricum* and *A lepidum*) Moreover, it makes possible interpretation of the chromosome pairing seen in the two triploid hybrids obtained earlier, and already mentioned The thirty-six bivalents found in both of these triploid hybrids must arise from pairing between chromosome sets common to both diploid and tetraploid parents The triploid hybrids are backcross hybrids between an allotetraploid species and its two diploid parents The relationships can be symbolized as follows, where letters represent the chromosome sets present, and the underlining bars indicate the composition of the bivalents formed in meiosis *A viride* = $\underline{VV}$, *A trichomanes* ssp *trichomanes* = $\underline{TT}$, *A adulterinum* = $\underline{VV}\,\underline{TT}$, *A adulterinum* × *trichomanes* ssp *trichomanes* = $V\underline{TT}$, and *A viride* × *adulterinum* = $\underline{VV}T$

It proved possible to synthesize the diploid hybrid *Asplenium viride* × *trichomanes* ssp *trichomanes* (= VT) This hybrid shows complete failure of chromosome pairing with seventy-two univalents present at meiosis (Fig 1) It should be possible to induce tetraploid sectors in this diploid hybrid by treatment with an agent inducing polyploidy, for example colchicine This procedure has, however, been unnecessary, because the fronds of the diploid hybrid have been found to produce spontaneously an appreciable number of viable spores which have in turn produced normal sexual gametophytes More than 1,000 prothalli have thus been obtained, and random fertilization of these prothalli has resulted in the production of more than 120 sporophytes which are morphologically inseparable from characteristic examples of natural *A adulterinum* So far, ten of these sporophytes have been cytologically examined To all intents and purposes, all these plants are tetraploid, with a normal meiosis showing $n=72$ bivalents (Fig 2), although one or more plants can be aneuploid for a single chromosome (In this genus, it is technically difficult to obtain complete certainty in observations of small irregularities in chromosome behaviour) Sowings of spores from two of the cytologically tested plants in both cases resulted in copious and uniform growths of prothalli, showing that the spores produced by these plants have a high degree of viability The prothalli have now produced an abundant crop of sporophytes, indicating in turn that these gametophytes are highly fertile

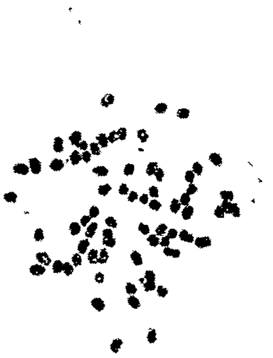

Fig 1 Permanent aceto-carmine squash preparation of meiosis in a synthetic diploid hybrid, *Asplenium viride* × *trichomanes* ssp *trichomanes*, showing seventy-two univalents (×1 000)

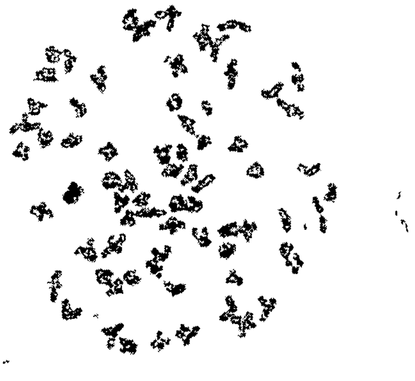

Fig 2 Permanent aceto-carmine squash preparation of meiosis in synthetic *Asplenium adulterinum*, showing seventy-two bivalents (×1,000)

The tetraploid nature of the sporophytes derived from the spores produced by the diploid hybrid clearly indicates that these spores must themselves be diploid; in other words, they contain an unreduced chromosome complement Their origin has not yet been critically studied, but it seems likely from observations already made[6] on a closely related hybrid of wild origin, *A trichomanes* ssp *inexpectans* × *viride*, that these spores arise by restitution of the spore mother cell nucleus after failure of meiosis to progress beyond first metaphase In this respect, it is significant that the spores produced by this wild hybrid have in a similar way given rise to fertile tetraploid sporophytes[7] Furthermore, this ready production of tetraploid sporophytes by the spores formed by a diploid hybrid has also been shown by myself and Reichstein[7] for a natural example of the hybrid *A trichomanes* ssp *trichomanes* × *viride* originally found wild in Switzerland by Dr W Gatzi (although not on serpentine rock) The morphology of this hybrid is virtually identical to that of the synthesized examples of this hybrid combination, while the chromosome behaviour observed in both of the two wild diploid hybrids and their tetraploid progeny is indistinguishable from that seen in the synthetic hybrids[6,7] The phenomenon of the production of spontaneous tetraploid progeny from a diploid hybrid has also been observed elsewhere in *Asplenium*. Wagner and Whitmore[8] obtained tetraploid plants of *A. ebenoides* from spores produced by a wild example of the diploid hybrid *A. platyneuron* × *rhizophyllum*, although in this case only a few prothalli were obtained.

In the case of a plant such as *Asplenium adulterinum* where the propagules are both very numerous and light, and are readily dispersed by air currents, the possibility of contamination of the experimental cultures by the very species one is attempting to reconstruct must be considered. The conditions in which these experiments have been carried out do not entirely exclude the possibility of the introduction of spores of adventive origin. Moreover, some plants of *A. adulterinum* of wild origin were in cultivation on our site at the time the experiments were in progress. All sporophytes produced by the prothallial cultures obtained from the synthetic *A. viride* × *trichomanes* ssp. *trichomanes* hybrid were retained. In spite of the presence of very numerous different sources of fern spores in our greenhouses, only 4 per cent of the sporophytes obtained are of evidently contaminant origin. Another more positive control has been possible. An exactly comparable experiment has been conducted in an immediately adjacent series of cultures using the spores produced by another diploid *Asplenium* hybrid of synthetic origin, *A. viride* × *fontanum* (L.) Bernh. This hybrid also shows complete failure of chromosome pairing. Tetraploid sporophytes have again been produced, showing a regular meiosis with $n = 72$ bivalents. In this case, the total progeny obtained again exceeds 120 sporophytes, more than 95 per cent of which are of the expected morphology. A fertile tetraploid form of this hybrid has never yet been found in the wild, so contamination of the prothallial cultures by the actual species one is attempting to synthesize is in this instance totally impossible.

Returning to the newly obtained synthetic examples of *Asplenium adulterinum*, a critical test of the degree of identity existing between the natural species and its synthetic simulant is possible. Comparison in uniform conditions of cultivation has shown that certain strains of *A. adulterinum* from different localities show small but constant morphological differences with respect to such characters as the shape of the pinna and the position on the rachis of the point of change in its colour from brown to green (unpublished results of Lovis and Reichstein). Use of these strains as one parent has made it possible to distinguish hybrids from self-fertilized plants in the progeny resulting from crosses made between natural and synthetic examples of *A. adulterinum*. (Because the prothalli are hermaphrodite and self-compatible, it is not possible entirely to prevent some self-fertilized progeny as the outcome of a hybridization experiment.) Cytological examination of these hybrids shows a regular meiosis, indicating that close homology exists between the chromosomes of natural examples of *A. adulterinum* and those of its synthesized facsimile.

I thank Professor I. Manton and Professor T. Reichstein for their advice and encouragement, and the staff of the experimental gardens of this department for their assistance in cultivation of the plants involved in this investigation.

IMMUNOLOGY

Immune Haemolysis: Reaction of the Terminal Complement Component

THE lytic step of the complement reaction sequence is biologically very important. An attempt to determine its nature by indirect methods was previously made in this laboratory[1,2]. Another direct approach to the problem was conceived when it was shown that the "classical" third component of haemolytic complement (C') comprises at least six distinct factors[3,4].

Sensitized sheep erythrocytes (EA) which had been reacted with the first eight components of complement (C'1–C'8, for nomenclature see ref. 5) were prepared and we have investigated the reaction of these EAC'1–8 cells with the last component of complement (C'9). This communication summarizes our findings, which will be published in detail later.

EAC'1–8 cells were prepared by a two-step procedure. First, sensitized sheep erythrocytes were incubated at 32° C with diluted guinea-pig serum adsorbed on zymosan, prepared by the method of Lepow and Leon[6]. After 10 min the cells were collected and washed twice. These cells were readily lysed by guinea-pig or pig serum in the presence of 0.010 M ethylenediaminetetraacetic acid (EDTA), which indicated that they had at least been brought to the state EAC'1a,4,2a. In a second step, these erythrocytes were incubated for 20 min at 37° C with a serum fraction containing C'3, C'5, C'6, C'7 and C'8. This fraction was obtained by gel filtration on 'Sephadex *G*-200' of the euglobulins of pig serum. EAC'1–8 cells were washed and stored at 4° C in veronal buffered saline containing Ca^{++} and Mg^{++} (VBS) which was used as a diluent throughout[7].

Our procedure for the preparation of EAC'1–8 is based on findings of Wellensiek and Klein. They fractionated guinea-pig serum on a 'Sephadex *G*-200' column and reported that of the C' components reacting subsequent to C'2 only the terminal one is eluted together with the albumin ("4*S* peak") while the others are associated with the 7 *S* gamma globulins[8]. When tested with reagents prepared according to Wellensiek and Klein[8,9], we observed that after gel filtration of the pig serum the distribution of the late acting C' components in the column eluate was similar to that described for guinea-pig serum.

EAC'1–8 are haemolysed by pig C'9 as well as by functionally pure preparations of guinea-pig and human C'9. They are characterized by a slow, spontaneous lysis when stored in VBS as well as by a decreased resistance against hypotonic solutions of NaCl, lysolecithin or sodium-deoxycholate[10]. Similar observations were reported with cells which had reacted with the first eight components of guinea-pig complement[11]. EAC'1–8 showed no detectable loss of reactivity with C'9 when stored in VBS at 4° C for more than 100 h or at 37° C for 48 h. They were, however, no longer reactive to C'9 after treatment with pronase, a proteolytic enzyme from *Streptomyces griseus* (Calbiochem, Lucerne, Switzerland). A sample of 10^8 EAC'1–8 was incubated with 125 µg of pronase in 1.0 ml for 60 min at 37° C.

We prepared C'9 from pig serum. The euglobulin fraction was precipitated by 2-ethoxy-6,9-diamino-acridine lactate ('Rivanol', Farbwerke Hoechst) and subsequently by ammonium sulphate (35–50 per cent saturation). Further purification was achieved by column chromatography on '*CM*-Sephadex *C*-50', gel filtration on 'Sephadex *G*-200' and by preparative zone electrophoresis. Functionally pure human C'9 was prepared similarly. Pig C'9 showed a single band in analytical agarose-polyacrylamide electrophoresis[12] with the migration characteristics of a fast β-globulin. Its activity is rapidly destroyed at 56° C with a half-life time of 7.5 min. Human C'9 (C'T) was reported to have a half-life of 6 min at 56° C (ref 13)

The activity of C′9 was completely abolished by dialysis against 0 10 M mercaptoethanol which suggests that there are disulphide bonds in the native molecule Di-isopropyl-fluorophosphate (DFP), *p*-chloromercuribenzoate (*p*CMB), $HgCl_2$ or iodoacetamide had no effect on the C′9 activity which would seem to indicate that seryl or SH-groups are not essential for the haemolytic activity of the component (Table 1)

Antibodies against pig C′9 were prepared by immunizing rabbits with functionally pure preparations incorporated into complete Freund adjuvant The antiserum was heat inactivated to destroy C′9 and absorbed with EAC′1–8 It strongly inhibited the activity of pig C′9 and, to a lesser extent, that of human C′9 (Table 2)

The dose-response curve of the reaction between EAC′1–8 and C′9 suggested a one-step mechanism The curve was concave to the abscissa and gave a straight line after transformation to the $Z = -\ln(1-y)$ plot according to Mayer[14] which indicated a linear relationship between the number of hits per cell and the C′9 concentration The reaction was temperature dependent and had its optimum at 42° C. Na-Cu-chlorophyllin (Merck, Darmstadt) was found to be a potent inhibitor which stopped the reaction within 10 s With the aid of this compound we were able to show that at 37° C the reaction between EAC′1–8 and C′9 started without a lag phase and was completed after 20 min A typical experiment is shown in Fig 1

In addition to Na-Cu-chlorophyllin a number of other inhibitors were detected (Table 3) While the inhibition by Cu^{++} ($CuSO_4$ or $Cu(NO_3)_2$) and Zn^{++} ($ZnSO_4$) was completely reversible by dialysis against cold VBS, the addition of Fe^{++} ($FeSO_4$) or Fe^{+++} ($FeCl_3$) to C′9 led to an irreversible inactivation of the component Its activity was not restored by dialysis against VBS or by the addition of the chelating agent 1,10-phenanthroline hydrate (Merck, Darmstadt) These findings are not in accord with recent observations of Hadding and Muller-Eberhard[15], who reported that 1,10-phenanthroline induces lysis of EAC′1a,4,2a,3,5,6,7,8 prepared with human C′ components Iron ions in the divalent form inhibited the lysis of the cells by both phenanthroline and human C′9, whereas trivalent iron had no such effect The authors inferred from their results that the capacity of C′9 and of phenanthroline to lyse EAC′1a,4,2a,3,5,6,7,8 might be caused by a reaction with Fe^{++} and that activation of C′8 sites on the cell might be brought about by withdrawal of Fe^{++}

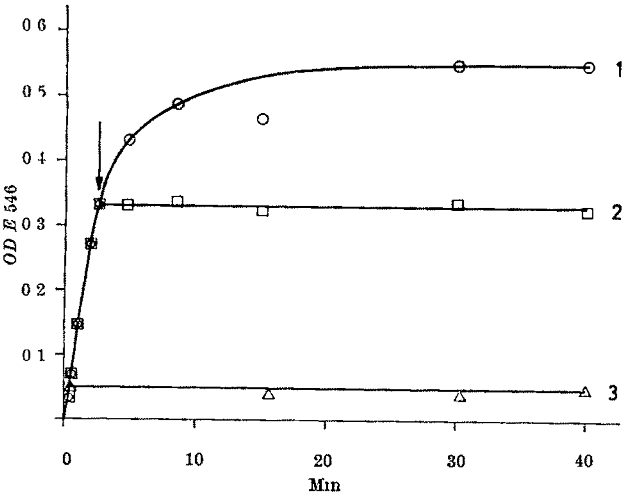

Fig 1 Kinetics of the reaction between EAC′1–8 cells and C′9 at 37° C Three flasks, 1, 2 and 3, each containing 10 ml of EAC′1–8 (2 × 10^8 cells/ml) were set up in parallel Flasks 1 and 2 received 10 ml of C′9, and flask 3, 10 ml of VBS At the times indicated 1 0 ml samples from flask 1 were pipetted into 0 5 ml of VBS containing 20 μg of Na-Cu-chlorophyllin (curve 1) To flask 2, 10 ml of VBS containing 40 μg of Na-Cu-chlorophyllin/ml was added at $t = 2$ 5 min as indicated by the arrow Samples of 1 5 ml were withdrawn at the times indicated (curve 2) To flask 3, 10 ml of VBS containing Na-Cu-chlorophyllin was added at $t = 0$ min Samples of 1 5 ml were withdrawn at the times indicated (curve 3) After sampling, each tube was left for a further 60 min at 37° C before the degree of haemolysis was determined

Table 1. EFFECT OF VARIOUS SUBSTANCES ON THE ACTIVITY OF C′9

Substance	Concentration (M)	Percentage inhibition
Mercaptoethanol*	1 0 × 10^{-1}	100
DFP†	1 0 × 10^{-3}	0
*p*CMB‡	1 0 × 10^{-3}	0
$HgCl_2$§	1 0 × 10^{-6}	0
Iodoacetamide ‖	2 0 × 10^{-2}	0

* C′9 was first dialysed against mercaptoethanol for 60 min at room temperature followed by dialysis against VBS or 2 × 10^{-2} M iodoacetamide and then VBS

† 0 9 ml C′9 and 0 1 ml 10^{-2} M DFP in anhydrous isopropanol were incubated at 37° C After 30 min EAC′1–8 were added and incubation was continued for 60 min

‡ C′9 was incubated with *p*CMB at 37° C After 15 min EAC′1–8 were added and incubation was continued for an additional 60 min Lysis in tubes containing *p*CMB and C′9 was 20 per cent higher than in tubes containing only C′9 EAC′1–8 treated only with *p*CMB showed no haemolysis within 60 min

§ $HgCl_2$ was incubated with C′9 at 37° C After 15 min EAC′1–8 were added and incubation was continued for an additional 60 min EAC′1–8 treated with $HgCl_2$ for 60 min at 37° C showed no haemolysis

‖ C′9 was dialysed against iodoacetamide for 4 h in the cold The iodoacetamide was then removed by dialysis against VBS

Table 2 INHIBITION OF C′9 BY ANTI-C′9 RABBIT ANTISERUM

C′9 preparation	Reciprocal dilution of antiserum	Percentage inhibition
Pig	1,200	100
Pig	5,000	50
Human	20	50

A sample of 0 5 ml of C′9 was incubated with 0 5 ml of antiserum dilution at 37° C After 20 min EAC′1–8 cells were added and incubation was continued for an additional 60 min

Table 3 INHIBITION OF HAEMOLYSIS OF EAC′1–8 BY C′9

Inhibitor	μg	Percentage inhibition*
Na-Cu-chlorophyllin	10	100
Na-chlorophyllin	50	100
Germanin (Bayer 205)	200	100
Heparin-Na (Nordmark, Hamburg)	740 (=100 international units)	34
	Concentration (M)	
$FeSO_4$	1 2 10^{-4}	86
$FeCl_3$	1 2 10^{-4}	97
$CuSO_4$	1 5 10^{-5}	97
$Cu(NO_3)_2$	1 5 10^{-4}	100
$ZnSO_4$	1 0 10^{-4}	100

A sample of 10^8 EAC′1–8 cells was incubated for 60 min at 37° C in the presence of the inhibitor with an amount of C′9 sufficient to give 70 per cent lysis in the controls Total reaction volume was 1 5 ml

* No inhibition was observed when EAC′1–8 cells were pretreated with the inhibitor and were washed before the addition of C′9

Table 4 EFFECT OF 1,10-PHENANTHROLINE HYDRATE AND 2,2-BIPYRIDINE ON EA AND EAC′1–8

Concentration (× 10^{-3} M)	Percentage haemolysis*	
Phenanthroline hydrate	EA	EAC′1–8
2	0	0
4	0	0
6	0 9	0
8	1 0	0
10	1 0	0
12	2 3	1 8
13	5 0	5 3
14	9 9	10 5
15	14 9	15 9
Bipyridine		
5	0	0
10	0	0 4
20	0	2 1
24	1 3	2 3
30	4 7	5 9

A sample of 10^8 cells was incubated for 60 min in the presence of the Fe^{++}-chelating agents in a total reaction volume of 1 5 ml

* Values were corrected for lysis of the controls not containing the chelating compounds

In view of these discrepancies, the effect of Fe^{++}-chelating agents on EA and EAC′1–8 was re-examined using 1,10-phenanthroline hydrate and 2,2-bipyridine (Merck, Darmstadt) As a result, EA and EAC′1–8 were slightly haemolysed to the same extent, but only by the highest concentrations used (Table 4) Thus in our system neither Fe^{++} ions nor phenanthroline seem to affect

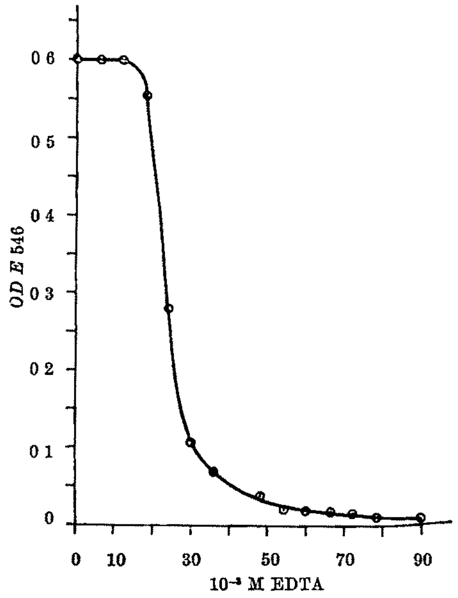

Fig 2 Effect of EDTA on the haemolysis of EAC′1–8 cells by C′9 Isotonic solutions of different concentrations of EDTA were prepared by mixing 0 090 M EDTA, *p*H 7 6, with appropriate volumes of 0 15 M NaCl EAC′1–8 cells were incubated with C′9 for 60 min at 37° C

C′9 or EAC′1–8 specifically. Most likely the results are caused by differences in the preparation of the cells and of C′9 They may, however, be caused by the different species origin of the complement components A detailed comparative study of the two systems may resolve these questions

Lysis of EAC′1–8 after reaction with C′9 was not observed in isotonic 0 090 M EDTA, *p*H 7 6 Lysis occurred, however, when these cells were washed and reincubated in VBS This type of inhibition was found by Frank *et al*[16] who studied the transformation of E^+ to ghost and haemoglobin It can be seen in Fig 2 that the effect of EDTA is already clear at concentrations much lower than 0 090 M Moreover, the degree of the spontaneous lysis of E, EA and EAC′1–8 is markedly reduced when these cells are stored in 0 090 M EDTA as compared with their lysis on storage in VBS (unpublished observations) Thus EDTA seems to exert an unspecific stabilizing effect upon the erythrocyte membrane which might be strong enough to inhibit the release of haemoglobin from EAC′1–8 treated with C′9

The described experiments do not yet allow any conclusions to be made concerning the molecular events of the terminal step in immune haemolysis We hope that with the aid of the established system more precise studies will be possible

PHYSIOLOGY

Pheromones from the Abdominal Brushes of Male Noctuid Lepidoptera

Recent investigations have shown that benzaldehyde is the chief component of the pheromone extracted from the abdominal scent-brushes of *Leucania impura* (Huebner), *Leucania conigera* (Schiffermueller) and *Phlogophora meticulosa* (Linnaeus)

Many types of male eversible organs occur within the Lepidoptera, and these have been assumed to function as scent producing organs with some role in courtship The extreme variation in both their structure and location implies that these organs have evolved independently many times in response to a powerful selection pressure Their role has recently been described in detail for a large diurnal species, the Queen butterfly (*Danaus gilippus*)[1] In the related species *Lycorea ceres*, the components of the scent have been chemically identified[2] The courtship display of nocturnal moths is more difficult to observe, because moths do not readily produce natural behavioural responses in captivity

The brushes of the species we investigated are of the type restricted to noctuid moths and described by Eltringham[3] The brush is supported on a lever attached to the base of the first apparent abdominal sternite (Fig 1), and usually lies in a lateral pocket stretching from sternites three to five The lips of the pocket are tightly pressed together to restrain the hairs and to limit evaporation of the scent Eltringham suggested that the scales lining the pocket might produce the scent, but, unknown to him, Stobbe[4] had already described a pair of small glands giving rise to a thread of intertwined hairs which lead into the brush Excision of these glands from living moths, with appropriate controls, showed that they secrete the characteristic scent The brush is everted by specific muscles acting on the lever to pull it from the pocket and away from the abdomen A muscle across the back of the basal plate of the brush contracts to spread the apically expanded hairs After use, the brush returns to lie alongside the abdomen, and from there it is slowly pulled back into the pocket by hairs lining the lips, to be reloaded with scent

Laboratory observations of the courtship of *Phlogophora meticulosa* showed that mating took place at about dawn (4 a m in June). The males remained at rest until the female exposed her sex gland and released the attractant pheromone As this dispersed, the males became active and flew upwind towards the calling female In several cases, a male was observed to evert the brushes in the immediate vicinity of the female, followed at once by an attempt to copulate The brushes remained expanded for only 1 or 2 s On no occasion was copulation attempted without prior eversion of the brushes The scent thus naturally liberated by one moth could be easily discerned by the human nose This is apparently the first time that the use of these brushes in the courtship display of a noctuid moth has been confirmed

To extract the volatile material, the lever was cut and the brush lifted out and dropped straight into solvent (methylene dichloride) As long as the hairs are prevented

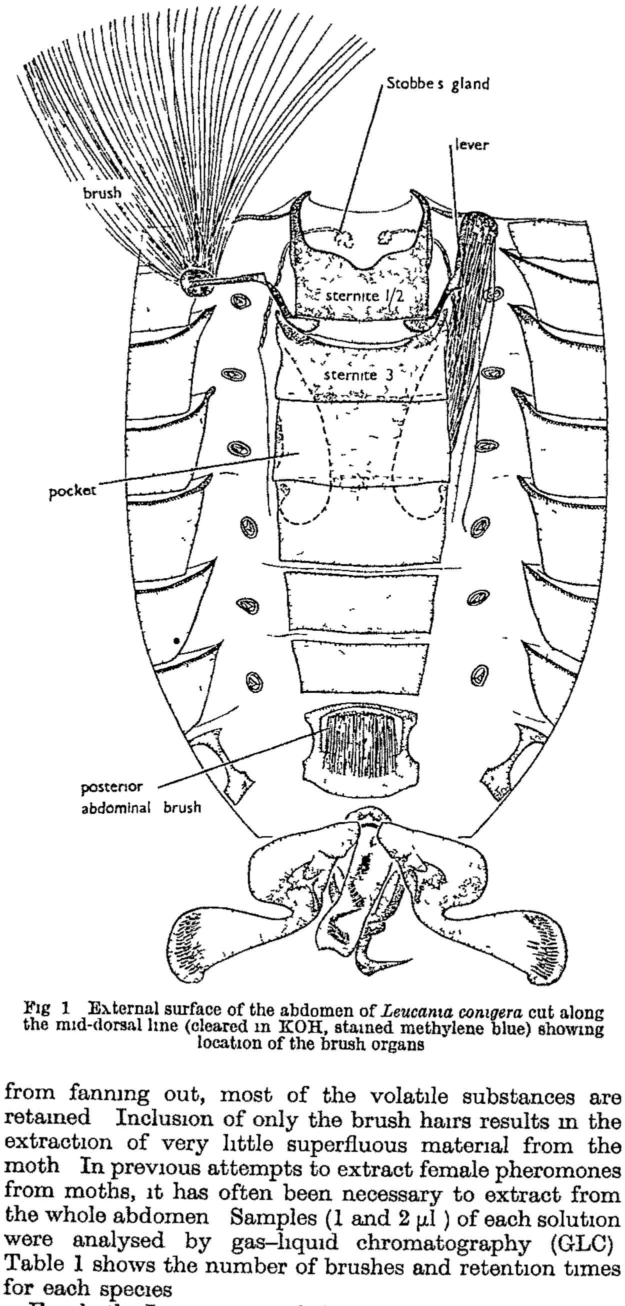

Fig 1 External surface of the abdomen of *Leucania conigera* cut along the mid-dorsal line (cleared in KOH, stained methylene blue) showing location of the brush organs

from fanning out, most of the volatile substances are retained Inclusion of only the brush hairs results in the extraction of very little superfluous material from the moth In previous attempts to extract female pheromones from moths, it has often been necessary to extract from the whole abdomen Samples (1 and 2 µl) of each solution were analysed by gas–liquid chromatography (GLC) Table 1 shows the number of brushes and retention times for each species

For both *L impura* and *L conigera* the single GLC peak had the same retention time as benzaldehyde, as shown by an enlargement of the peak area on addition of a benzaldehyde marker Analysis of both solutions on a mass spectrograph showed the presence of a major component with a molecular weight of 106 which exhibited the characteristic fragmentation pattern of benzaldehyde[5] These results confirm that benzaldehyde is a chief component of the scent The characteristic almond smell of the two *Leucania* species seems to be the main component of the scent (*Leucania pallens* (Linnaeus) also smells strongly of almonds) For *Lycorea*, Meinwald was forced to assume the presence of a scent component in trace amounts, in addition to the three components identified to account for the characteristic odour

Table 1

Species	No of brushes	Quantity of solvent (ml)	GLC retention time* (min)
Leucania impura	214	5	20
Leucania conigera	54	5	20
Phlogophora meticulosa	40	1	20+24
Apamea monoglypha	142	1	63

* On a Pye 104–14 gas chromatograph equipped with a flame ionization detector and 30 per cent 'Apiezon *L*', on an 80–100 mesh 'Embacil' column, operating at 100° C with an argon carrier gas flow of 40 ml /min

An estimate of the quantity of scent extracted was obtained by running a quantitative control of benzaldehyde on the chromatograph The sample of 214 brushes from *L impura* contained about 10^{-3} g, which gives an average of 5 µg for each brush This figure is certainly an underestimate because losses must occur through evaporation and oxidation to benzoic acid The amount must vary from moth to moth, depending on the length of time from the previous discharge

Of the two peaks recorded from *P meticulosa*, the first was shown to be benzaldehyde, the second has not yet been identified The longer retention time peak from *Apamea monoglypha* (Hufnagel) implies a less volatile compound with higher molecular weight A component with a molecular ion weight of 284 was observed on mass spectrographic analysis

Three biological functions can be suggested for this scent (1) It may act on other males as a deterrent Aldehydes are well known as major components of defensive secretions and benzaldehyde is secreted by several millipedes (*Diplopoda*) It is possible that other males lose interest in a mated female more quickly through distribution of a male scent than by cessation of a female one, although the rapid disappearance of the scent makes this doubtful (2) It may act on the female as a species specific signal to prevent cross-breeding This seems to be ruled out because *L impura*, *L conigera* and probably *L pallens* all have the same scent Because all three species are common grass-feeders and are active at the same time of year, the mechanism to prevent cross-breeding may lie in the time of mating The three species also possess additional posterior abdominal brushes, however, the role of which is not yet known The male scent may act as an isolating mechanism between some species Varley[7] has described several noctuid genera where closely related species have very different types of scent-organ or none at all (3) It may act on the female as an aphrodisiac to induce mating A combination of (2) and (3) seems to be most likely

We thank Professor G C Varley for encouragement, and the Hon Miriam Rothschild for suggesting that one of us (R T A) should investigate the chemistry of insects M C B acknowledges a Science Research Council research studentship

Effect of Humming on the Visibility of a Stabilized Retinal Image

Rushton[1] has recently described a series of ingenious experiments which demonstrate the effect of humming on the induction of stroboscopic patterns in non-fluctuating illumination By introducing a number of controls and by studying the perception of presumably non-peripheral phenomena (such as the Pulfrich pendulum), he concludes that the strobing is induced because the humming sets up a mechanical vibration of the retina, and not, as might be suggested, by inducing "central strobing" through driving the rate of neuronal firing.

These conclusions are supported when one considers the effect of humming on the perception of a perfectly stabilized image—which, of course, cannot be displaced with respect to the retina by mechanical vibration. We have recently performed two simple experimental studies, employing this technique, which are relevant to Rushton's work. In the first we examined the effect of humming on the perception of the pattern in Fig. 1 when viewed as a stabilized image (the method of stabilization involves the production of an intense, clear after-image by illuminating the target with a 1,250 J flash 1 ms in duration[2,3]). It has been suggested that the fringes or shadow patterns observed when Fig. 1 is fixated in normal illumination are the result of some central scanning process, but they are more probably caused by eye-movement scanning, for the phenomena are not observed in stabilized vision[4]. Humming at 100 Hz might possibly induce the fringe patterns in the after-image if the principal effect of humming were to drive neural input at some point in the visual system, but it would be expected to have no effect if it were merely causing retinal vibration, because both retina and after-image vibrate in phase. In fact, a series of simple observations reveals that humming does not induce any significant change in the perception of Fig. 1 as an after-image.

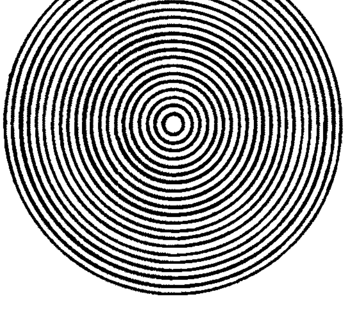

Fig. 1

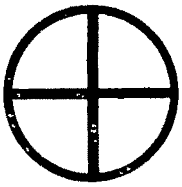

Fig. 2

In a second, quantitative, study, an after-image of the line drawing shown in Fig. 2 was viewed in four different conditions, and in each case the time was recorded from the first appearance of the perfect image to the first change of any kind. This is known as "time to first disappearance". The after-images were viewed with eyes closed, about 10 in. from a screen illuminated from behind to a brightness of 0.9 log ft.-lamberts in an otherwise dark room. In the first three conditions, the illumination was steady—provided by a d.c. lamp—and in the fourth it was strobed at 100 Hz. The first two (control) conditions were identical except that in one case a 100 Hz tone was heard through earphones while viewing, and in the other no tone was used. In the third (experimental) condition, the subject was required to hum in tune with the tone. Thus the four conditions and times were as in Table 1.

Table 1

	Mean time (s) (25 trials)	*S.D.*
(*a*) d.c. illumination, no sound	14.8	9.1
(*b*) d.c. illumination, 100 Hz tone	7.2	6.7
(*c*) d.c. illumination, 100 Hz tone hum	7.0	6.1
(*d*) Illumination strobed at 100 Hz, no sound	3.8	2.4

There is a highly significant difference ($P < 0.005$) between conditions (*a*), ($b + c$), and (*d*), but no difference between (*b*) and (*c*) themselves ($P > 0.3$). This makes it clear that the onset of fragmentation of the after-image is facilitated by the auditory input or by strobing the background, but that any change in the behaviour of an after-image which might be ascribed to the effect of humming really results from the sound input itself and not from the method of generating it. The effect of strobing the background is so much greater that it would not seem that the humming was operating by "strobing" the visual system central to the retina. This therefore provides interesting support for Rushton's conclusions.

Effect of Light and Dark on Secondary Induction of Cornea in Tadpoles of *Rana temporaria*

WE have found a close connexion between the functional state of the retina and certain inductive processes in the developing vertebrate eye. Such studies, carried out during functional ontogenesis, were based on theoretical concepts of the unity of the evolutionary origin of functional and formative phenomena and their close connexion in animals[1,2].

First, we repeated previous experiments on the secondary induction of cornea in skin grafted onto the eye[3,4], but subjected the tadpoles to different light conditions. A blinking pattern, highly active for retina, obviously accelerated induction, which was retarded in the dark[5]. Light of different quality (sunlight, colour), according to its physiological effect on the retina, either accelerated or slowed the induction of Wolffian regeneration in the larvae of *Pleurodeles waltlii*, and this was reflected in the structure of regenerating lenses[6].

Different light conditions also influenced temporarily the development of the more stable intact eye. Thus flashing light accelerated the differentiation of the retina photoreceptors and, consequently, primary induction of the cornea in young tadpoles, however, constant light (8 h/day) caused increased accumulation of ganglionic cells and enhanced the development[7] of the lens. It is interesting that the growth of eyes and optical brain lobes in chick embryos was accelerated under the influence of flashing light[8].

The influence of adequate external stimuli on the ability of the retina to induce the production of cornea by altering the specific and spontaneous function of the retina needs to be explained. It is possible that alternating light and dark influences not so much the inductive ability of the retina as the reactivity of the skin graft covering the eye, which in tadpoles[9,10] is very sensitive to light. We have investigated this important problem.

Experiments were carried out on tadpoles of *Rana temporaria* with three-membered hind limbs without digits In such tadpoles the electroretinogram is already formed[11], showing that their visual apparatus is functional In 390 experiments, skin was successfully grafted from the host's back onto the outer cornea of the recipient's right eye There were two series of experiments (1) the retina was kept intact on the operated eye, and (2) at the same time as grafting the optic nerve was cut so as to induce a limited retro-degeneration and destruction of the inner layers of the retina which it does in this species[12,13] About half the specimens in each series were exposed to diffused sunlight and natural days and nights (control) while the other half were kept in a dark chamber which was opened only in red light All other conditions (such as temperature and food) were identical for both groups All tadpoles developed normally

The dynamics of the transformation of the pigmented skin into hyaline cornea under the influence of the eye was first examined on flat preparations The stages of transformation were evaluated with a four-mark system —, $\pm$, ± and + Many of these eyes were also studied histologically

On the ninth day of the experiment, one out of ten controls (of series 1 and 2) showed signs of depigmentation of the skin grafts ($\pm$) We then chose daily at random ten "light" and ten "dark" tadpoles from both series and watched the changes which were visible in the grafted skin until the new cornea formed (+) in the control groups This allowed us to store data using two phase variance analysis (first the symbols were replaced by the figures 0, 1/3, 2/3, 1) and draw graphs which showed the difference in the rate of formation in light and darkness It is important that this difference is insignificant in series 1 but strongly increases in series 2 The influence of light and time on the secondary induction of cornea in the grafted skin in series 1 ($P > 0\ 95$) and even more so in series 2 ($P > 0\ 999$) is unquestionable

Our results undoubtedly depended on the different state of the retina in the two series of tadpoles In series 1 the retina was normal and in series 2 the ganglionic and inner nuclear layer opposite the pupil always degenerated under the influence of the optic nerve intersection Any alteration of formative properties of the light-sensitive skin graft could not influence results, because control and experimental tadpoles of both series were kept in the same conditions of light and darkness

These and our previous data on the effect of adequate external stimuli on very sensitive formative connexions in the vertebrate eye agree with what is known about the physiology of vision Thus when excited by light, the normal retina induces in good time new cornea in the skin graft, but in tadpoles in the dark the specific retina activity is replaced by its weaker spontaneous activity and the formation of a new retina is retarded After the optic nerve had been cut the photoreceptors, closely connected with cornea formation, do not lose their electrophysiological[14] and formative activity[15] They seem to increase the rate of the physiological reaction, probably because of acceleration of the inductive action of the denervated eye in the light and slowing down in darkness The latter phenomenon is also explained by the partial destruction of the inner layers of the retina, indicative of the decrease in the spontaneous production of impulses by the darkened retina

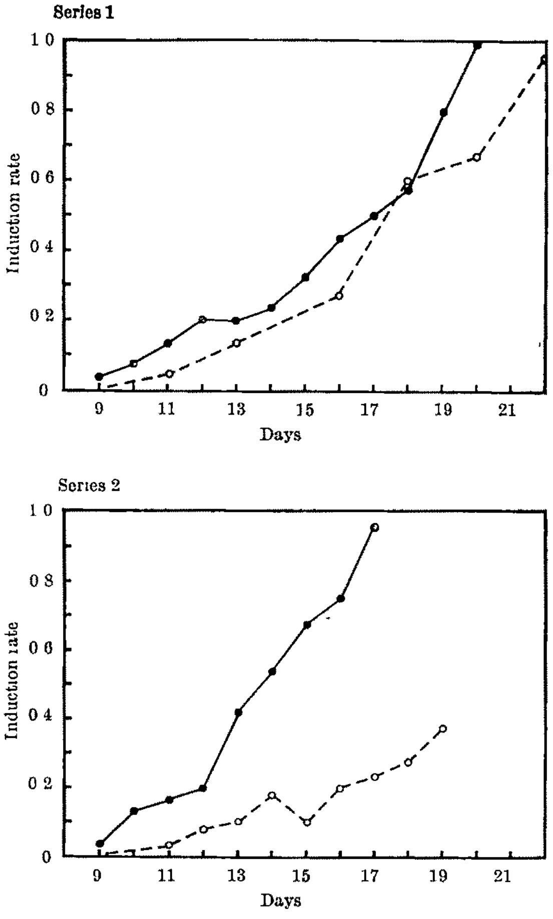

Fig 1 Dynamics of the secondary cornea induction under the influence of normal (series 1) and denervated (series 2) eye in light and darkness ●, Control (light), ○, experimental (dark)

Some Aspects of Heart Function in *Patella vulgata* L.

WITHIN the pericardium of *Patella vulgata* L , in addition to the auricle and ventricle, there is a third chamber of the heart, the bulbus aortae or pseudo-chamber (Fig 1, *Ba*). This chamber is situated laterally to the ventricle (*V*) and all blood leaving the ventricle passes through a valve into the bulbus aortae before leaving the pericardium by the anterior or posterior aorta (*Aa* and *Pa*) The function of the bulbus aortae is of considerable doubt, for although it is histologically indistinguishable from the ventricle it has not previously been observed to contract rhythmically Wegmann[1] considered the bulbus aortae to be a sub-division of the ventricle, but all later workers argue that it is the fused, swollen bases of the anterior and posterior aortae[2]

The effect of tidal exposure on the heart rate of limpets while on the shore at Millport, Isle of Cumbrae, was recorded by impedance pneumograph This method involved placing two silver electrodes through the shell so that they touched the pericardium, and connecting these to an impedance pneumograph designed to detect pulsatile changes in volume, which was a c coupled to a multi-channel pen recorder Similar work on bivalves[3] has shown a retardation of heart rate during littoral exposure (to about 15 beats/min) and an increase during tidal coverage (to about 30 beats/min) The recordings obtained from *Patella*, however, indicate that the heart rate is about 33 beats/min when the tide is out (Fig 2*A*), but the recordings taken when the tide was in show a much slower rhythm of about 18 beats/min although the beats were of greater amplitude (Fig 2*B*), the precise rates varying from individual to individual This is not the original heart beat because the latter is in places superimposed on the slower rhythm (Fig 2*B*, *X*) The slower rhythm occasionally ceased when the tide was in and did not start at all when the tide was in and a storm was blowing The heart rate, when distinguishable, displayed a slight, but significant, increase when the tide was in, to about 38 beats/min

The slower rhythm was at first thought to be the result of the effect of the rasping movements of the radula because these are of a similar frequency Laboratory tests, however (Fig 2*C*), have shown that radula movements have no effect on heart recordings made in a similar manner to those of Fig 2*A* and *B*, and therefore this explanation seems unlikely to be true The effects of temperature were also excluded as the air and sea temperatures were similar at the time of the field experiments

The other most probable source of the slower rhythm is the bulbus aortae, but it proved impossible to take pneumograph recordings of heart beat while at the same time observing the bulbus aortae In an attempt to verify this hypothesis, a number of experiments were carried out First, the left half of the roof of the pericardium was removed, leaving intact the fibres joining the ventricle to the roof of the pericardium (Fig 1, *Pvf*), and a thread was attached round the auricular–ventricular junction to an isometric myograph Contractions of the bulbus aortae, which was visible through the pericardial wall, were marked manually onto the recorder (Fig 2*D*) Second, the whole roof of the pericardium was removed and threads were attached round the auricle and round both the ventricle and bulbus aortae to isometric myographs The bulbus aortae is attached at both ends to the pericardium and only contractions of the bulbus aortae were recorded in this manner, not those of the ventricle (Fig 2*E*)

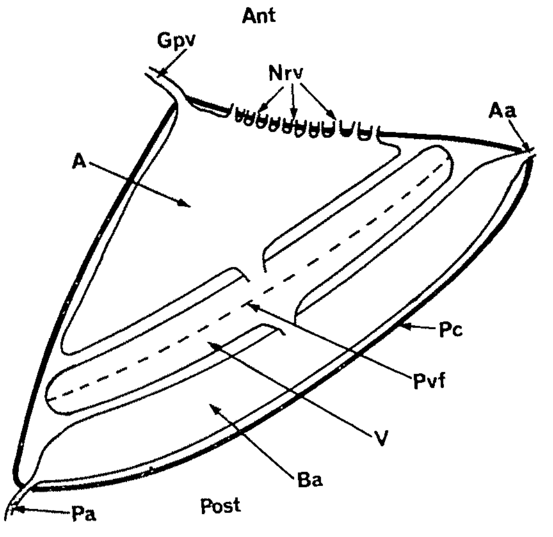

Fig 1 *Patella vulgata* L Dorsal aspect of the pericardium and heart *A*, Auricle, *Aa*, anterior aorta, *Ant*, anterior, *Ba*, bulbus aortae, *Gpv*, great pallial vein, *Nrv*, veinlets from the roof of the nuchal cavity, *Pa*, posterior aorta, *Pc*, wall of the pericardium, *Post*, posterior, *Pvf*, fibres joining the dorsal wall of the pericardium to the ventricle, *V*, ventricle

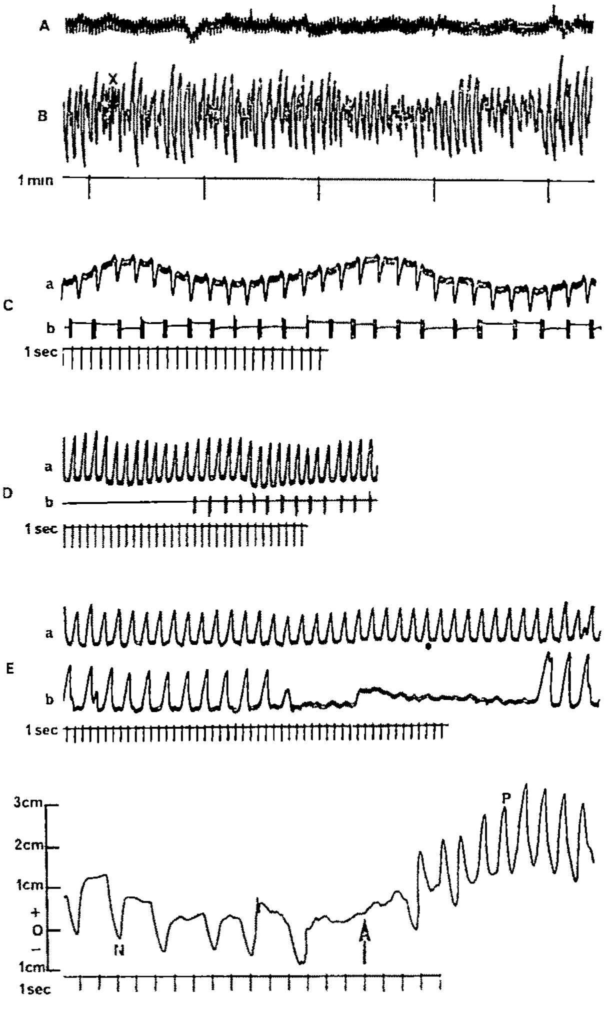

Fig 2 *Patella vulgata* L Recordings of the heart beat (*A*) Pneumograph recording during tidal exposure, (*B*) pneumograph recording when covered by the tide *X* is superimposed ventricular contractions, (*C*) pneumograph recording (*a*) while moving and feeding on glass with (*b*) simultaneous manual record of the rasping movements of the radula, (*D*) isometric recording of the contractions of the auricle and ventricle (*a*) with contractions of the bulbus aortae manually marked (*b*), (*E*) isometric records of auricular contractions (*a*) and contractions of the bulbus aortae (*b*), (*F*) pressure recording from within the pericardium and, after the arrow, from within the ventricle while the bulbus aortae was beating Pressure is reduced in the pericardium as the bulbus aortae contacts *N*, but the pressure increases in the ventricle during ventricular systole *P* Pressure in cm of water

Unsuccessful attempts were made to obtain pressure recordings from within the bulbus aortae and simultaneously from within the pericardium Fig 2*F*, however, shows a record from within the pericardium adjacent to the bulbus aortae, followed by a record of ventricular contractions (which were continually occurring), obtained when the cannula was manipulated into the ventricle (at arrow). The low frequency of the bulbus aortae appears as a negative pulse (*N*) in the pericardium, and ventricular contractions as positive peaks (*P*) in the ventricle

In each case the faster rhythm/slower rhythm ratio is as follows (letters refer to those of Fig 2), $A/B=1\cdot84$, $Da/Db=1\cdot35$, $Ea/Eb=1\cdot33$ and $F=1\cdot98$. The pressure recording caused the least disturbance to the animal and thus gives the best correlation This indicates that the contractions of the bulbus aortae bear a similar relation to the frequency of auricular/ventricular contractions as do the recordings taken when the tide is in to those obtained when the tide is out The records also show that the control of the bulbus aortae is independent of the auricle (and presumably the ventricle), for the contractions are capable of being arrested in spite of the continuing auricular beat (Fig 2*E*)

These results suggest that the recordings obtained when the tide was in are caused by the rhythmic contraction of the bulbus aortae The recordings illustrated (Fig 2) are almost the only successful laboratory observations of the contractions When the animals from which the original records were obtained were moved on their own substrate into the mobile laboratory housing the recording apparatus, only a recording similar to Fig 2*A* was obtained, even after synchronous tides were produced experimentally On replacing the limpets on the shore the recordings were similar to those originally obtained

The bulbus aortae of *Patella* may have either an active or a passive function The enlargement of the aorta of *Busycon canaliculatum* and the aortic bulb on the posterior aorta of the clam *Tridacna* would seem to play only a passive part, both acting simply to even out the pressure surges produced by the ventricle[4,5] That of *Tridacna* may also act as a reservoir for arterial blood squeezed back during adduction[6] The aortic ampulla of *Pila globosa* is, however, contractile, probably performing a more active role[7] The bulbus aortae of *Patella*, it is suggested, acts as an accessory pump, for it is clearly capable of strong contractions independently of the ventricle It may also act to synchronize blood flow with movements of the odontophore, though Fig 2*C* would seem to contradict this in that the bulbus was not contracting during feeding

The initiation of beating of the bulbus aortae may be concerned with the oxygen demand produced as a result of locomotion and feeding The oxygen consumption of *Patella* is at its highest when the tide is in[8], and the buccal muscles of *Buccinum* have a very high oxygen consumption[9] Most littoral animals are inactive when the tide is out and it may require periods of sustained activity for the beat of the bulbus aortae to be initiated Specimens of *Patella* kept in the laboratory feed only intermittently and possibly there is not a consistent enough high demand for oxygen for the beat to be initiated

It would therefore seem that the bulbus aortae of *Patella vulgata* chiefly acts as an accessory pump, providing increased blood flow to satisfy the higher oxygen demand produced as a result of the increased activity when the animal is covered by the tide

I thank Dr E R Trueman for advice and encouragement, and Professor J G Phillips and the director of the Scottish Marine Biological Association for facilities This work was carried out while in receipt of a Science Research Council research studentship

Observations on the Presence of Titanium and Zinc in Human Leucocytes

THE electron probe microanalyser makes possible rapid, precise localization and quantitation of elements in thin biological tissue during visual scanning of specimens This communication describes a study of its use in analysis of the metal content of normal and malignant blood cells The instrument used (Cameca, Paris) had an optical magnification of 400 diameters with a resolving power of about 0 5μ The X-ray spectrographs use quartz crystals which are bent and ground to a focusing circle of 250 mm radius Detectors are proportional counters, one with a beryllium window and another of gas-flow type with a thin plastic window

Of the numerous substrates possible for such work, single crystal disk wafers of highly polished silicon were found most suitable because such substrates (1) facilitate optical examination of specimens by reflected light in the electron probe instrument, (2) provide sufficient electrical conductivity to discharge specimens, (3) ensure the absence of particulate impurities, and (4) yield a low background of continuous X-rays

Under a 30 kV beam of electrons of 10^{-7} A, focused on a spot about 1μ across, single cells give useful X-ray spectra in which intensities of some lines are as high as 1,000 c p s with a peak-to-background ratio of at least 10-fold and sometimes as high as 100-fold

Specimens of whole blood, bone marrow and lymph nodes were obtained from human sources The blood smears were produced by the standard technique on opposing surfaces of silicon disk and glass cover slips, taking care to avoid contamination by dust, finger contact, stains, fixatives or substances containing metal The bone marrow specimens were similarly prepared by direct application and smearing on the substrate surface without anticoagulants, fixatives or dilutants The leucocytes from lymph node sources were isolated by gentle agitation of the node with 'Teflon' tweezers in physiological sodium chloride solution without buffering additives, immediately after surgical lymph node biopsy Smears were made of the resulting undiluted cell suspension and of separately prepared centrifugal concentrates

During a study of the intracellular cation content of human erythrocytes subject to dialysis after removal from the frozen state, the metal content of leucocytes which contaminated the specimens was also investigated Unexpectedly large amounts of titanium and zinc were occasionally found A repeated search was then made of the leucocytes of normal peripheral blood, with only rare similar findings Because of the difficulty in identifying the morphological subtypes of leucocytes in unstained specimens with reflected illumination at 400 diameters, attention was directed to relatively pure strains of cells to learn whether granulocytes or lymphocytes were the source of the signals Initial tests on blood of a subject with predominantly lymphoblastic forms in the circulating blood gave clear evidence of the presence of high concentrations of titanium and zinc in many cells This was in the range of 10^6 to 10^8 metallic atoms per cell This was substantiated by similar findings in three additional cases Control specimens from normal sources were strikingly different

Fresh bone marrow aspirates rich in leucocytes were then examined Again, cells containing titanium and zinc were found, but apparently much more frequently in cases of lymphoblastic lymphoma involving the marrow as shown in Table 1 In an effort to refine the technique further, fresh lymph nodes removed during surgical biopsies were next examined Again, cells containing titanium and zinc were found, most frequently in cases of lymphoblastic lymphoma Table 2 shows the results of a randomized white cell count and simultaneous

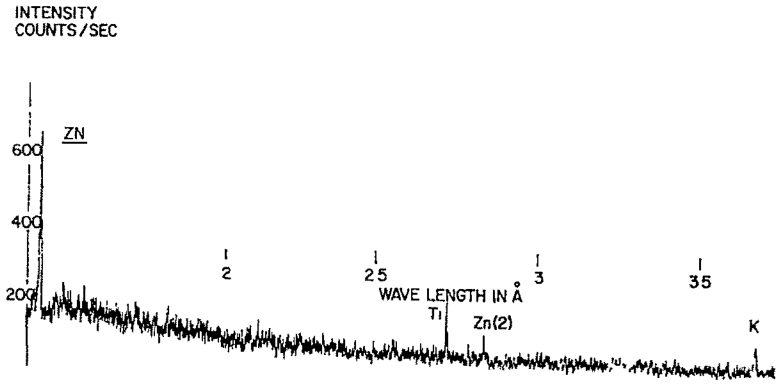

Fig 1 X-ray emission spectrum from a single lymph node cell, *Kα* lines ofpotassium, titanium and zinc Specimen from patient with Hodgkin's lymphoma.

recording of titanium and zinc emission X-rays on a strip chart recorder of the counting rates. A total of 300 cells were scanned in all cases but one, in which only 200 cells were available Randomization was accomplished by selecting two peripheral and one central field in a 300 μ^2 area The recorder settings were adjusted to reveal clearly on the chart zinc and titanium X-ray signals of intensity as low as 10 c p s Such an intensity of X-ray signal may be compared with an intensity of some 60,000 c p s on solid metal specimens of zinc or titanium under identical conditions of the electron beam Thus the sensitivity of the technique can be estimated to be below 0 1 per cent of a pure metal standard or, alternatively, a detectable limit of about 10^{-14} g of metal atoms per cell. This sensitivity was entirely adequate for our purpose and no attempts were made to increase sensitivity Fig 1 shows a typical X-ray spectrum of a single cell in which zinc, potassium and titanium are seen

Table 1 FREQUENCY OF CELLS CONTAINING TITANIUM AND ZINC IN WHITE CELLS FROM BONE MARROW

Specimen	Diagnosis	Frequency of occurrence of cells containing titanium and zinc
1	Normal marrow, toxic goitre	0 out of 100
2	Normal marrow, secondary anaemia	3 out of 200
3	Normal marrow, histiocytosis	0 out of 200
4	Myeloblastic leukaemia	1 out of 100
5	Lymphoblastic leukaemia	15 out of 85
6	Multiple myeloma	9 out of 300

Table 2 NUMBER OF CELLS CONTAINING TITANIUM AND ZINC IN 300 CELL RANDOMIZED COUNTS ON LEUCOCYTES EXTRACTED FROM LYMPH NODES

Specimen	Diagnosis	Number of titanium and zinc cells
1	Normal	1
2	Normal	1
3*a*	Hodgkin's lymphoma	25
3*b*	Hodgkin's lymphoma, centrifuged	16
4	Normal	1*
5	Lymphosarcoma and Hodgkin's lymphoma	15
6	Non-lymphomatous, undifferentiated carcinoma	1

* 200 cell count

Among samples from lymph nodes, blood and bone marrow from some thirty-six persons with malignant and non-malignant haematological diseases, variations in the ratio of zinc to titanium were observed In cases of lymphoblastic lymphoma, multiple myeloma and Hodgkin's disease, however, the atomic ratio of zinc to titanium maintained a constant value estimated at 3 or 4 to 1 In a single cell the two metal atoms, if present, were at precisely the same location Additional cells were observed in which titanium or zinc occurred alone, and often in a region smaller than the electron probe beam Occasional material containing zinc and titanium larger in physical size than a single cell was, however, observed This could represent either an extracellular deposit or an agglomerated mass of denatured cells Such extracellular material was not included in the results reported here.

The intracellular role of these metallic elements in the structure or function of leucocytes is unknown, but we considered that the differences in frequency of their presence in leucocytes from normal as opposed to immature (malignant) sources were sufficient to justify this preliminary report Multiple biochemical and physiological studies will be necessary to establish the function, if any, of these metals in cells

We thank Miss Phyllis Baudanza and Dr Gilbert Eberle for technical assistance, and the US National Academy of Sciences–National Research Council for a visiting scientist grant at the US Army Natick Laboratories, where exploratory investigations of technique were conducted on other biological materials We also thank James C Elms and Dr W C Dunlap for encouragement and equipment Dr Charles Berry requested the initial study of the use of the probe in connexion with cell changes observed in space flight This work was supported in part by grants from the US National Institutes of Health

Efficacy of β-Adrenergic Blocking Agents in inducing Histamine Sensitivity in Mice

THE usually high resistance of mice to the lethal effects of histamine can be greatly reduced in certain strains by some substances The most potent of these histamine sensitizing substances is probably the so-called histamine sensitizing factor (HSF) of *Bordetella pertussis*[1]. Recently, substances with β-adrenergic blocking activity, such as dichloroisoproterenol (DCI), pronethalol ('Alderlin'®) and 4-(2-isopropyl-amino-1-hydroxyethyl) methane sulphonanilide HCl (*MJ*-1999), have also been shown to increase the sensitivity of mice to histamine[2,3] Some of these agents, such as DCI, have been found highly effective in reducing histamine tolerance[2] Preliminary work with DCI and the *CFW* strain of mice, reared in our laboratory, confirmed that treating mice with DCI does induce histamine sensitivity, but we did not find that DCI was effective in the small doses (0 005 mg/kg) reported by Fishel *et al* [2] With the advent of other β-adrenergic blocking agents, we felt it would be of value to test the histamine sensitizing effects of these agents and to determine if some were more efficient in this respect than others In order to duplicate more closely the experimental conditions used by Fishel *et al* [2], we used female *CFW* mice obtained from Carworth Farms, New City, New York

The mice, weighing 20–24 g, were treated intravenously with various doses of β-adrenergic blocking agents given in 0 2 ml of physiological saline and were challenged

Table 1 COMPARISON OF THE EFFICACY OF VARIOUS β-ADRENERGIC BLOCKING AGENTS IN INDUCING HISTAMINE SENSITIVITY IN MICE

Dose (µg/mouse i.v.)	β-Adrenergic blocking agent DCI†	Pronethalol	Butoxamine HCl	Propranolol
240	7/10*	8/10	8/10	10/10

Table 2 SD_{50}s* OF β-ADRENERGIC BLOCKING AGENTS TO INDUCE SENSITIVITY TO A CHALLENGE WITH 0.5 MG OF HISTAMINE

β-Adrenergic blocking agent	Trial First	Second	Third
DCI	77.3 µg†	12.7 µg	68.6 µg
Pronethalol	71.3 µg	—	55.3 µg
Butoxamine HCl	125.0 µg	—	46.6 µg
Propranolol	0.22 µg	2.0 µg	1.0 µg

* Calculated by the method of Reed and Muench[8].

† Calculated quantity of blocking agent required to sensitize half of the mice to the lethal effects of the histamine challenge.

15–20 min later with an intraperitoneal injection of 0.5 mg histamine base in 0.2 ml of saline. Pronethalol, DCI, butoxamine-HCl and propranolol ('Inderal'®) were compared for their ability to increase the sensitivity of mice to histamine. Propranolol in doses of 2–240 µg/mouse gave consistent sensitization to histamine (Table 1). The other three drugs also sensitized mice to histamine, but greater doses were required to produce a consistent and high degree of sensitivity. These results were obtained in other experiments in which propranolol was always found to be more potent than DCI, pronethalol or butoxamine-HCl.

Table 2 summarizes the result obtained in three experiments with respect to calculated SD_{50}s for the β-adrenergic blocking agents to induce sensitivity to a standard challenge with 0.5 mg histamine. Some differences in degree of sensitization were noted in the various experiments and could only be explained by differences in the lots of mice employed. Even more striking differences had been observed when *CFW* mice raised in our laboratory were employed in this type of experiment. DCI was much less effective in sensitizing *CFW* mice raised in our laboratory than *CFW* mice purchased directly from Carworth Farms. This variation in lots of mice, or in mice raised in slightly different conditions, is at present unexplained, but it is a difference that makes it essential to use proper controls in this type of experiment.

Of the compounds we have tested, propranolol is the most potent on a weight basis of the β-adrenergic blocking agents in its histamine-sensitizing activity, and approaches in potency the soluble preparations of *B. pertussis*. Like other β-blocking agents, it produces histamine sensitivity within 15–20 min after injection and this sensitivity begins to disappear 1 h later. As with DCI and pronethalol[4], mice treated with propranolol could be protected from death by introducing about 7.5 µg of *l*-epinephrine intravenously 30 s after the histamine challenge.

Fishel *et al.*[5] have advanced a hypothesis which attempts to explain histamine sensitivity in mice after treatment with either β-adrenergic blocking agents or HSF from *B. pertussis*. They proposed their hypothesis as follows: "... the *B. pertussis* organism either possesses a component or causes the host to elaborate a substance with a steric configuration complementary to the β-adrenergic receptors. Because of natural affinity, this substance combines with the β-receptors and occupies the site normally available for the adrenergic transmitter, i.e., adrenaline and/or noradrenaline. When such an animal is challenged with histamine or serotonin, the antagonistic action of the excessively released catecholamines is blocked at the β-receptor level, leaving the α-adrenergic activities unopposed. The resultant imbalance produces a combination of unfavourable metabolic, and, consequently, smooth muscle as well as neural adjustments, culminating in a reduced resistance to histamine and serotonin."

An impressive amount of data has been reported which indicates that some sort of β-adrenergic blockade may indeed operate in pertussis-treated mice[6,7]. There are observations, however, which do not support some aspects of this hypothesis. There is little doubt that β-adrenergic blocking agents produce histamine sensitization, but proof is lacking that an imbalance between the α and β receptor responses is responsible for death after challenge with histamine. If an imbalance between the α and β receptor responses to endogenously released catecholamines were indeed the underlying cause of sensitization to histamine, one would not expect animals treated with β-blocking agents or with HSF from *B. pertussis* to be protected by injection of epinephrine. This type of protection has, however, been reported[3,4]. In addition, animals treated with β-blocking agents or HSF would be expected to be more sensitive than normal animals to injection of epinephrine, but this is not the case. Fishel *et al.*[2] reported very little difference in LD_{50} values when epinephrine was administered intraperitoneally to normal and pertussis-treated mice. We obtained similar results after giving *l*-epinephrine intravenously. The LD_{50}s in normal and HSF-treated mice were 8.0 and 6.4 µg, respectively, in an experiment in which epinephrine doses started at 0.0156 µg/mouse and increased to 16.0 µg/mouse in two-fold increments.

With the available data, it is quite tempting to suggest that histamine sensitivity in mice is caused by a blockade of the β-adrenergic receptors. As suggested by Nickerson[9], however, it cannot be assumed that all the effects of β-adrenergic blocking agents are caused by blockade of the β-adrenergic receptors. It does seem significant, however, that histamine sensitivity has been obtained with all β-adrenergic blocking agents tested (DCI, butoxamine-HCl, pronethalol, propranolol and *MJ*-1999), thus indicating that the β-adrenergic receptors may be involved in histamine sensitization in mice.

We thank Mr Joseph Ayers for technical assistance, Dr J. W. Black, Imperial Chemical Industries, Ltd., for 'Alderlin'®, Dr A. Sahagian-Edwards, Ayerst Laboratories, for 'Inderal'® and Dr R. A. Salvador, Burroughs Wellcome and Co., for butoxamine-HCl.

Skeletal Abnormalities in the Hindlimbs of Young Cats as a result of Hypervitaminosis A

HYPERVITAMINOSIS A causes extensive confluent exostosis formation of the cervical spine in adult cats[1,2]. It was initially reported that no juvenile osteodystrophy occurred in this disease[1], but an abnormal hindquarter gait was described later in a group of young cats receiving large daily doses of vitamin A (ref. 2). No explanation of this abnormal gait was given and the condition was therefore studied further.

A litter of six healthy 8 week old kittens was divided randomly into two groups of three, whose diet consisted of raw meat and milk. The first group received no vitamin A supplementation and each cat in the second group was supplemented for 4 weeks with a daily oral dose of 100,000 I.U. of vitamin A acetate in polyethylene glycol and isopropanol. To prevent rickets due to a possible interaction between vitamin A and vitamin D (ref. 3), all cats received calcium and vitamin D supplementation throughout the experiment.

From the beginning of vitamin A supplementation the cats showed a marked disinclination to walk and depression of appetite. Immediately after cessation of vitamin A dosing, appetite returned, but reluctance to walk remained. Two weeks later the cats had a distinctly abnormal hindlimb gait which became more severe with time and was not a result of weakness. Their limbs appeared disproportionately short, particularly the hindlimbs. During walking, extension of the stifle joints was restricted and the hocks projected laterally. One cat from each group was killed after a further 4 weeks. After another 6 weeks some toes of the remaining test cats were observed to be shortened (Fig. 1). These animals and the two remaining controls were killed in the seventeenth week of the experiment—13 weeks after the cessation of vitamin A supplementation.

The outstanding pathological findings in the test cats included the following. (1) A dramatic shortening of the long bones of the limbs. (2) Alteration in structure of the stifle joint. The tibial crest was prolonged dorsally so that the tubercle lay above the remainder of the proximal epiphysis and rested against the distal femoral articular surface (Fig. 2). The femoral condyles were enlarged and displaced proximally so that the trochlea was the most distal part of the femur. (3) Irregular shortening of the metatarsal bones.

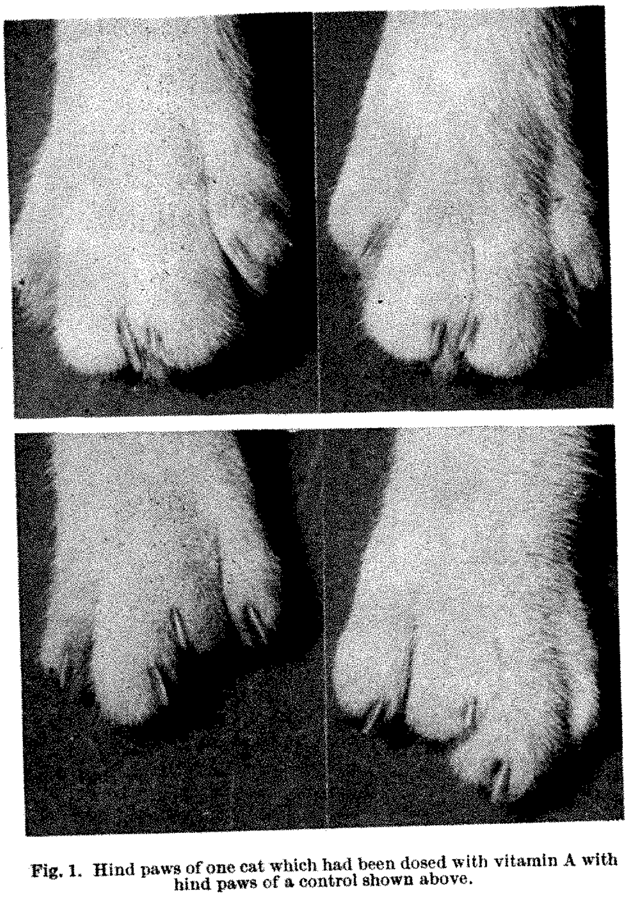

Fig. 1. Hind paws of one cat which had been dosed with vitamin A with hind paws of a control shown above.

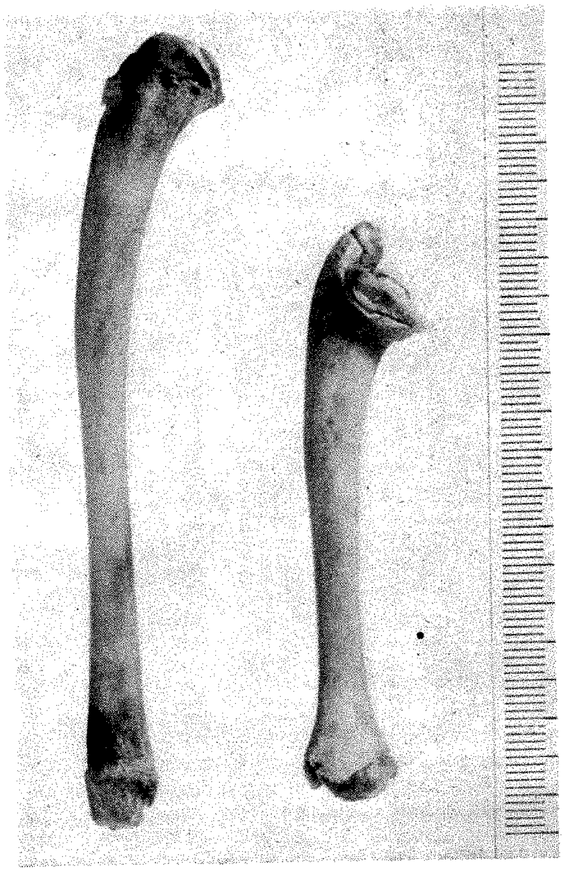

Fig. 2. The right tibia from a control (left) and hypervitaminosis A cat. (Normal size.)

The first two changes were bilaterally symmetrical in all three cats. The projection of the anterior proximal tibial diaphysis was longer and curved in a caudal direction in the cats killed at the later date. The third change was observed only in the latter two cats and was bilaterally symmetrical in one, affecting the third metatarsal bones. All four metatarsal bones were shortened in the right hind paw of the other cat, but only the fourth one was affected in the left. Histopathological examination of the distal ends of the metatarsal bones showed varying degrees of reduction of epiphyseal plates, sometimes with complete disappearance. In some bones, the medullary cavities of the epiphysis and diaphysis were continuous and a small piece of residual cartilage appeared free in the extended cavity, thus playing no part in the endochondral bone formation needed for longitudinal growth (Fig. 3).

It seems that after exposure to vitamin A for 4 weeks the growth of specific epiphyseal cartilages was arrested and as the bones continued to increase in diameter growth took place around the retarded epiphyseal cartilages and these were completely or partially resorbed.

These findings differ from those of Wolbach[4], using rats and guinea-pigs, who concluded that bone shortening in hypervitaminosis A was simply a result of premature closure of epiphyses caused by accelerated growth sequences. Our observations seem rather to support those of Fell and Thomas[5] and Thomas *et al.*[6], who found actual depletion of cartilage caused by dissolution of its matrix and loss of chondroitin sulphate in foetal mouse bones *in vitro* and in growing rats, respectively.

Fairbank[7] stated that the skeletal changes due to hypervitaminosis A in children resolved with no per-

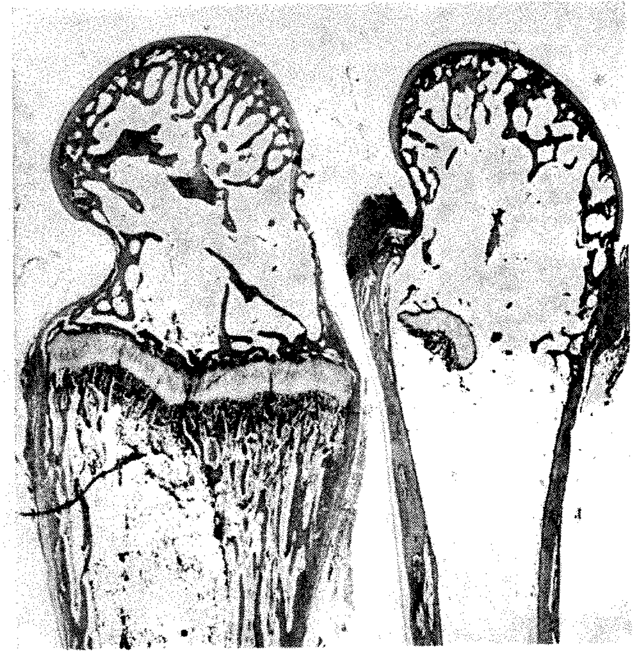

Fig. 3. Distal end of the right fourth metatarsal bone in a control (left) and hypervitaminosis A cat. (×8.)

sistence of bone lesions. Pease[8], however, reported permanent bone shortening in some children who suffered from hypervitaminosis A. The shortening of limbs was asymmetric and this was simply attributed to difference in weight bearing. The irregular nature of the shortening of metatarsal bones in young cats in this experiment is unlikely to have this explanation. The chief cause of the permanent gait abnormality in these cats was the bilaterally symmetrical prolongation of the anterior proximal tibia, making the extension of their stifle joints beyond ninety degrees mechanically impossible. Growth at the proximal end of the tibia takes place both at the cartilaginous epiphysis and also at an anterior fibro-osseous epiphysis[9,10]. The bone deformation observed in this study seems to be a result of restricted growth at the cartilaginous epiphyseal plate, while that at the anterior fibro-osseous region remained unrestricted, although probably modified by new stresses imposed by the changed stifle joint action.

High levels of vitamin A intake comparable with those in this experiment are possible for cats in natural conditions in Australia, where liver which is high in vitamin A content is readily available as pet food[1,2]. The osteodystrophy described here probably occurs in some kittens fed intensively for a short period on livers which are unusually high in vitamin A content.

Frequency, Conduction Velocity and Rate of Depolarization in Rabbit Auricle

THERE is evidence that an increase in heart rate is accompanied by a decrease in the velocity of impulse conduction in heart muscle[1-2]. We have therefore looked for interdependence between the frequency of the isolated rabbit atrium, the conduction velocity in the atrium and the maximal rate of rise of the atrial action potential.

In our experiments, the crista terminalis was isolated together with the S.A. node and a small part of the right atrium. The muscle strip was put in a tissue chamber, which was perfused with oxygenated McEwen's solution[3] at 37° ± 0·1° C. The muscle strip was continuously stimulated with rectangular voltage pulses (1V above threshold lasting 0·5 ms), administered with a bipolar silver electrode on the proximal part of the crista terminalis, near the head of the S.A. node.

Stepwise changes in the rate of stimulation were imposed on the muscle strip. In each programmed series of changes the intervals between the stimuli varied from 150 to 330 ms. Intervals were always increased or decreased in steps of 20 ms, and each new frequency was maintained for 15 s. A reference interval of 250 ms was used between two series of interval changes.

Transmembrane action potentials were recorded with microelectrodes at two sites on the endocardial side of the crista terminalis. All the electrodes, one stimulating and two recording, were placed in a straight line. Each interval between two successive action potentials, the intrinsic conduction time, was measured with a digital counter.

When the stimulus interval was abruptly shortened, the intrinsic conduction time was increased gradually, in about 8 s, to a new steady state. After a sudden increase of the interval the conduction time fell gradually to a steady state, also in 8 s.

When the usual interval change (20 ms) was augmented, the time required to reach a new steady state increased proportionally. The effect was the opposite when the interval change was diminished.

The average value of the steady state conduction time and its standard deviation were calculated from the twenty values of the intrinsic conduction time, which

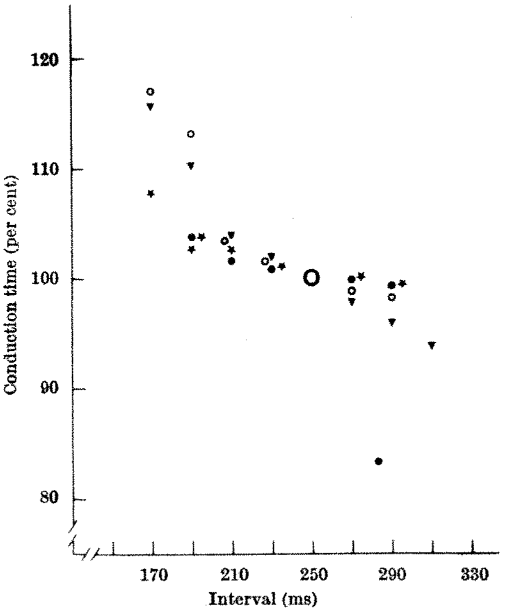

Fig. 1. Relation between steady state stimulus interval and intrinsic conduction time. Intrinsic conduction times are plotted as percentages of their value at the reference stimulus interval (250 ms).

were measured at the end of each frequency period ($\overline{S.D} = 0\ 4$ per cent, $S\ D_{\overline{S\ D}} = 0\ 2$ per cent).

Fig. 1 shows the results of four series of interval changes in one experiment Before we started a new series of changes the location of both microelectrodes was altered Almost the same relationship was found when two extracellular recording electrodes were used The maximal rate of rise of the depolarization phase of the atrial action potential was measured in each series

After a sudden change in frequency the rate of rise gradually adapted to a new steady state, which required the same time as the adaptation of conduction time During every increase in frequency we observed a significant decrease in the maximal rate of rise, whereas the opposite obtained during a decrease in frequency.

The average value of the maximal rate of rise together with its standard deviation were again calculated from the twenty values measured at the end of each frequency period ($\overline{S\ D} = 1{\cdot}9$ per cent, $S\ D_{\overline{S\ D}} = 0\ 5$ per cent)

After each series of interval changes the maximal rate of rise attained its previous reference value Between individual cells, however, this value varied from 50 to 110 V/s The relation between the stimulus interval and the maximal rate of rise as measured in six series of changes during one experiment is shown in Fig 2

Fig 3 shows superimposed action potentials recorded from the same cell at steady state levels during one series of interval changes The smallest potential with the slowest rate of rise corresponded to the shortest stimulus interval and the longest conduction time

During the frequency changes the level of the membrane potential did not change significantly, and repolarization was complete at all frequencies This observation cannot therefore be explained by the relation which was found earlier[4] between the level of the membrane potential and the rate of rise of the action potential We think that the relationship between frequencies exceeding 3 c p s. and the rate of rise might be explained by (a) incomplete reactivation of the Na-carrying system in crista terminalis fibres and (or) (b) insufficiency of the Na–K pump. The decrease in the rate of rise might be responsible for the decrease in conduction velocity[5]

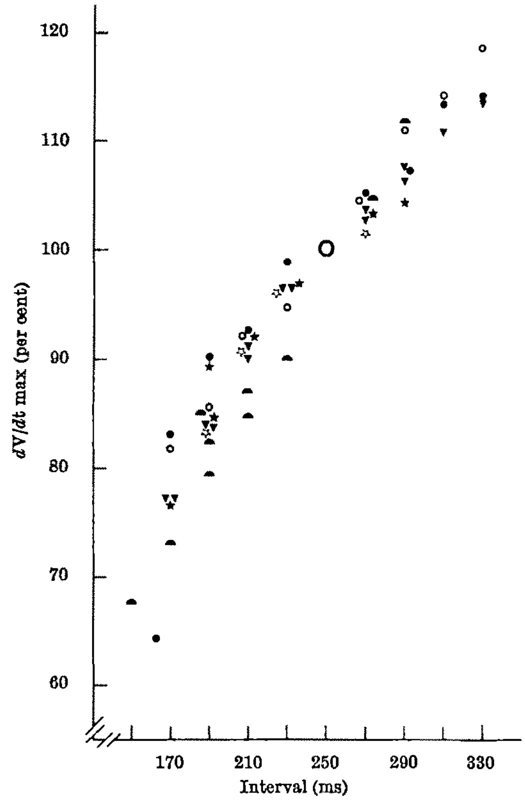

Fig 2 Relation between steady state stimulus interval and maximal rate of depolarization The maximal rates of rise are plotted as percentages of their value at the reference interval (250 ms)

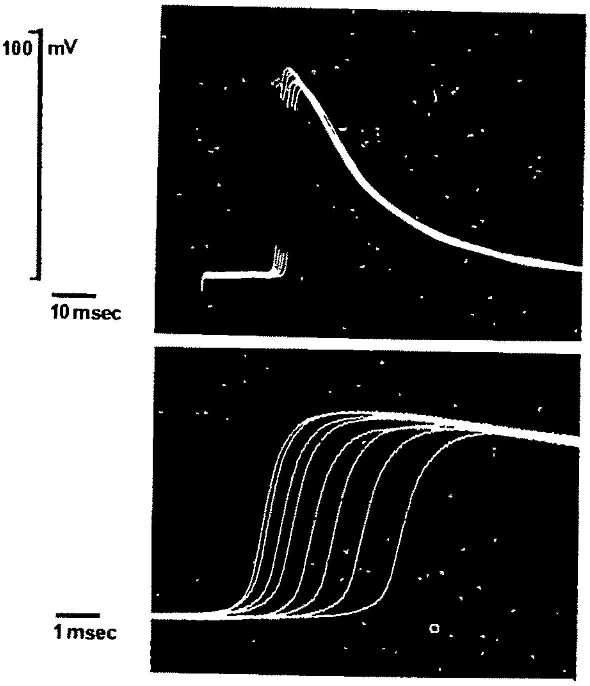

Fig 3 Superimposed action potentials at different stimulus intervals (170–330 ms) during one series of frequency changes The time base was triggered by the stimulus artefact

Immediate Circulatory Response to High Altitude Hypoxia in Man

Acute mountain sickness and high altitude pulmonary oedema are two acute medical problems for troops in the Himalayan terrain who frequently shuttle between sea level and high altitudes (10,000–16,000 ft) These two acute illnesses have some features in common time lag (they rarely occur within 12 h of arrival at the altitude or 96 h after arrival), throbbing headache, muscular cramps and pulmonary congestion. We have studied the acute circulatory response to high altitude hypoxia and investigated the extent to which shifts in the circulating blood volumes, if any, could be related to the time lag and clinical features of these acute illnesses

Thirty healthy volunteers were selected from the Indian Army. They were between 17 and 32 yr old (average 21 5 yr) and had never been exposed to high altitudes Sea level data were obtained at Delhi (height 650 ft) Right heart catheterization was performed by positioning a number 7 cardiac catheter in the pulmonary artery just below the valve The left atrium was entered by the percutaneous trans-septal method[1]. The right brachial artery was cannulated to obtain arterial blood pressures and dye curves. Consecutive dye dilution curves were obtained directly on

C, Control data at 650 ft. HA, Data at 12,000 ft. Numbers in parentheses indicate the number of subjects observed during the period

a 'Polyviso' channel through a continuous recording densitometer (Colson) by injecting 5 mg of indocyanine green dye into the main pulmonary artery and then into the left atrium The difference in the mean transit times of the two resulting curves was taken as the pulmonary transit time The cardiac output was measured from the dilution curves by the formula of Hamilton *et al* [2] The volume of blood between the pulmonary artery and the left atrium was obtained by multiplying the pulmonary mean transit time by the average cardiac output and this represented the pulmonary blood volume Similarly, the volume of blood between the pulmonary and brachial arteries was estimated by multiplying the pulmonary artery to brachial artery mean transit time by the average cardiac output and this gave the central blood volume[3] The total blood volume was determined by the Evans blue dye method Cerebral blood flow was estimated by the nitrous oxide technique of Kety and Schmidt[4] Peripheral blood flow was measured in the right forearm by venous occlusion plethysmography[5] All pressures were recorded through Statham *P23AA* strain gauge manometers on a four-channel single gun photographic system[6] Arterial blood *p*H, P_{CO_2} and P_{O_2} were determined using electrodes (Beckman) Cerebral blood flow and pulmonary blood volume were estimated in alternate subjects, other parameters were studied in every subject. For high altitude study, the team of investigators (nine doctors and four technicians) with equipment were airlifted a week earlier for acclimatization to an Army general hospital at 12,000 ft The subjects were subsequently flown in three batches at intervals of 5 days so that it was possible to observe the acute response in five to six subjects each day from day 1 to day 5 after arrival at the altitude Peripheral blood flow, however, was estimated in four subjects from each batch (total twelve subjects) daily from day 1 to 10 Physiological studies at Delhi and at the altitude were performed in identical conditions with regard to room temperature, equipment and observers

While there was no significant change in the total blood volume, peripheral blood flow diminished from the beginning, and remained so for the next 7 days On giving 100 per cent oxygen the diminished peripheral flow was somewhat increased. The cerebral flow increased by 40 per cent within 12–36 h and approached normal values by the fifth day Between 48 and 72 h the pulmonary blood volume increased by 80 per cent, and the central blood volume increased by only 28 per cent The arterial blood *p*H increased and P_{CO_2} and P_{O_2} fell from the beginning

Severinghaus *et al* [7] also found an increase of 33 per cent in the cerebral blood flow estimated in six men within 6–12 h of arrival at 12,500 ft Furthermore, we could relate the intensity of the headache of the sufferer to the greater increase in their cerebral blood flow Blood acid base changes observed by Severinghaus[7] showed similar patterns in the rise in arterial blood *p*H and fall in P_{CO_2} and P_{O_2}. Reduction in the peripheral blood flow has been observed in acute hypoxia by breathing 7 5 per cent oxygen[8] and also in congestive heart failure[9] The disproportionate increase in the pulmonary blood volume compared with the central blood volume (and no increase in the total blood volume) may contribute to the pulmonary congestion. Yu *et al* [10], on the other hand, by giving 12 per cent oxygen to sixteen patients with heart disease, found that the average central and pulmonary blood volume values decreased by 36 and 48 ml /m^2 The two groups are not comparable because our subjects were healthy young soldiers and we did not study induced hypoxia of only 10–15 min duration.

These observations cannot be critically reviewed, because comparable data on shifts in the circulating blood volumes caused by high altitude hypoxia are not available Decrease in the peripheral and increase in the cerebral blood flows, fall in the arterial blood P_{O_2} and P_{CO_2} with concomitant rise in *p*H can be related to the early onset of hyperventilation and respiratory alkalosis, throbbing headache and muscular cramps Marked increase in the pulmonary blood volume between 48–72 h may in part account for the maximum incidence of high altitude pulmonary oedema during this period It is concluded that time lag for the onset of the illnesses and such features as headache, muscular cramps and pulmonary congestion as seen in acute mountain sickness and high altitude pulmonary oedema may be related to the shifts in the circulating blood volumes and the fall in the arterial P_{O_2} and P_{CO_2} with rise in *p*H

We thank General A K Dev and Professor K L. Wig for their help We also thank the volunteers and Pershad, Sharma, Singh and Dumre for technical assistance

Influence of Temperature on Isometric Contractions of Rat Skeletal Muscles

THE influence of temperature on isometric contractions of rat skeletal muscles *in vitro* has been determined for fast extensor digitorum longus muscles (EDL) and slow soleus muscles (SOL) from 4 week old female Wistar rats. Isometric contractions were recorded with the long axis of the muscle vertical, with one tendon tied to the frame below and the other tendon tied to a short steel wire connexion which linked it with the tension transducer above. The compliance of the transducer (Statham, *Gl*-80-350) and the steel wire connexion to the muscle was $4·5 \times 10^{-5}$ cm/g and the natural frequency of vibration was 2 kHz. The muscle was immersed in about 100 ml of fluid (137 mM NaCl, 5 mM KCl, 2 mM $CaCl_2$, 1 mM $MgCl_2$, 1 mM NaH_2PO_4, 2 g/l of $NaHCO_3$ and 2 g/l of glucose) which was bubbled continuously with 95 per cent O_2 and 5 per cent CO_2. Neuromuscular transmission was blocked by adding $2·0 \times 10^{-5}$ g of tubocurarine chloride/ml of bath fluid. The muscles were stimulated directly by a transverse electrical field of 15 V/cm for 0·2 or 0·3 ms applied to the bath fluid by "massive" bright platinum electrodes set about 1 cm apart[1]. All recordings were made with the muscle set at the optimal length determined for twitch contractions at 20° C.

Fig. 1 shows representative records of isometric twitch and tetanic contractions of an EDL muscle and a SOL muscle from one animal. Three twitches were recorded (1/10 s) about 10 min after each change in temperature for a series in which the temperature was altered in 5° C steps from 35° C to 20° C and from 20° C to 35° C. For both muscles the maximum twitch tension (P_t) at a given temperature did not differ by more than 2 per cent for the ascending and descending series of measurements. The isometric tetanic contractions were recorded 10 min after each change in temperature in a separate series of measurements at 35° C, 20° C, 25° C, 30° C and 35° C in that order. The muscles remained in good condition throughout the experiment and the ratio of the maximum isometric tetanic tension (P_o) for the final contraction at 35° C to P_o for the initial contraction at 35° C was 1·05 for SOL and 0·985 for EDL. The results show that decrease in temperature from 35° C to 20° C decreased P_t and P_o of SOL and P_o of EDL, whereas P_t of EDL was increased 1·7 times. The decrease in temperature from 35° C to 20° C increased the isometric twitch contraction time (T_c) in both muscles from 10·75 ms to 37·5 ms for EDL and from 28 ms to 122 ms for SOL and also increased the time for half relaxation from 9·25 ms to 42 ms for EDL and from 36 ms to 170 ms for SOL.

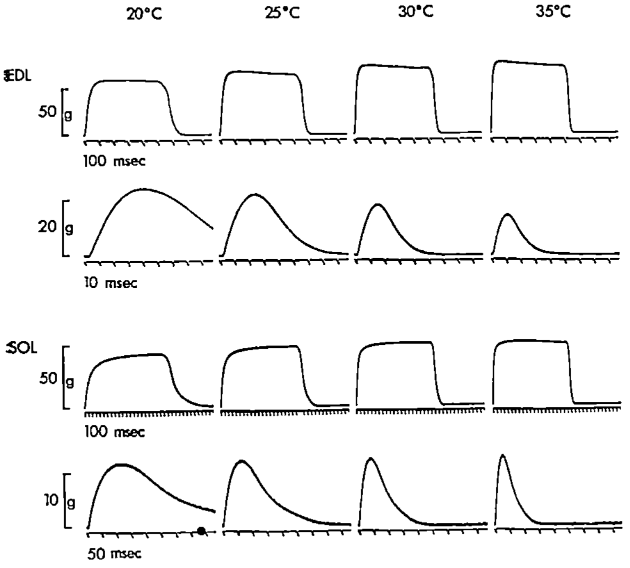

Fig. 1. Records of isometric twitch (10 ms and 50 ms time marks) and tetanic (100 ms time marks) contractions of extensor digitorum longus (EDL) and soleus (SOL) muscles at different temperatures. The frequencies of repetitive stimulation for tetanic contractions of EDL were 300 Hz at 35° C, 210 Hz at 30° C, 150 Hz at 25° C and 105 Hz at 20° C and the frequencies of stimulation of SOL were 250 Hz at 35° C, 180 Hz at 30° C, 125 Hz at 25° C and 90 Hz at 20° C. The rat was 4 weeks old and weighed 70 g. Muscle weights: EDL = 32 mg, SOL = 27·5 mg. Average muscle fibre length: EDL = 9·5 mm, SOL = 10·5 mm.

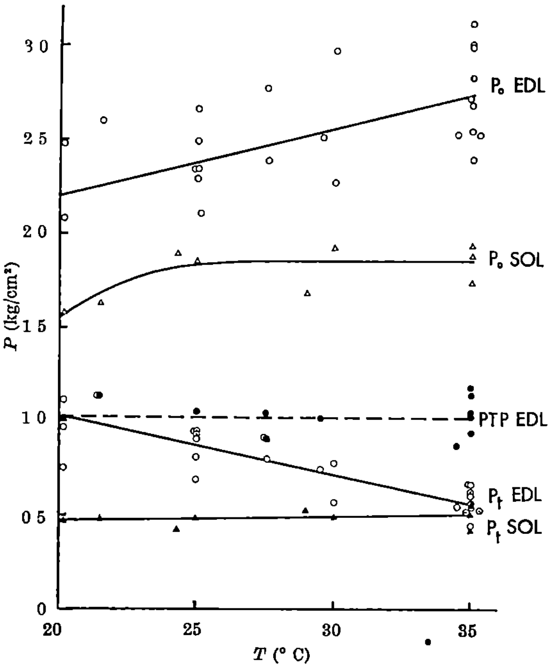

Fig. 2. The relation between maximum tension, P (ordinate in kg/cm² cross sectional area of muscle) and temperature (abscissa in ° C) for isometric twitch (P_t) and tetanic (P_o) contractions of fourteen extensor digitorum longus (EDL) and three soleus (SOL) muscles from four-week old rats (P_t of EDL = ○, P_t of SOL = ▲, P_o of EDL = ○, P_o of SOL = △). Responses of individual muscles at different temperatures were recorded for three SOL and five EDL muscles. Of the other nine EDL muscles, two were examined at 25° C only, two at 27·5° C only and 5 at 35° C only. Post-tetanic potentiation (PTP) was recorded at various temperatures in ten of the fourteen EDL muscles. The peak tensions of potentiated twitches recorded 10 s after the end of repetitive stimulation which produced maximum PTP have been plotted as filled circles (●) for comparison with the control pretetanic P_t. The average value for peak twitch tension in the potentiated twitches was 1·05 kg/cm² and is indicated in the diagram by the interrupted line.

The effects of temperature on P_t and P_o of fourteen EDL muscles and three SOL muscles are shown in Fig. 2. The linear changes in P_t and P_o of EDL are almost the same as those described before for rat triceps surae[2]. A similar influence of temperature has been described for amphibian muscle[3]. Recent measurements on the sartorius muscle of *Rana temporaria* which were stored at 3° C in October, using "massive" direct stimulation *in vitro*, show that P_t increases from 0·7 kg/cm² (0·5–0·96, $n = 5$) at 20°–22° C to 1·42 kg/cm² (1·21, 1·74, $n = 2$) at 2° C and that P_o decreases from 3·5 kg/cm² (3·37–3·63, $n = 5$) to 2·38 kg/cm² (2·06, 2·69, $n = 2$) for the same range of temperature (unpublished results of Close). The effect of temperature on contractions of SOL is similar to that described for neonatal rat EDL[4].

The differences in temperature dependence of contractions of EDL and SOL muscles may be related to differences in the effects of repetitive stimulation on these muscles. Post-tetanic potentiation (PTP) is usually absent in neonatal EDL and SOL and adult SOL, but appears in EDL during the first few weeks after birth. The peak twitch tension of EDL during maximum PTP at different temperatures has been plotted in Fig. 2 for comparison with the pretetanic P_t. The results show that there is little or no post-tetanic potentiation in EDL at 20° C and P_t at that temperature is about the same as the peak tension of the maximally potentiated twitch at other temperatures between 20° C and 35° C. In other words, the influence of temperature on contractions of EDL in the fully potentiated state is similar to the effect of temperature on contractions of SOL and neonatal EDL and involves a change in time course of the twitch response with little or no change in P_t At 35° C maximum post-tetanic potentiation leads to a two-fold increase in the peak twitch tension with little or no change in the time course of the response A similar degree of maximum post-tetanic potentiation has been observed in cat fast muscles at 37° C and frog twitch muscle at about 20° C and has been shown to occur in single muscle fibres[6-7]. A possible explanation for the differences in temperature dependence of frog twitch muscle and rat EDL muscle on one hand and rat SOL on the other is that a decrease in temperature decreases the intrinsic speed of shortening and the rate of removal of activator in all these muscles, thereby causing an inversely proportional increase in T_c with little or no change in P_t (ref. 4), but also increases P_t of frog twitch muscle and adult rat EDL, in much the same way that repetitive stimulation increases it, by increasing the degree of activation of individual muscle fibres with little or no change in the time course of the response. This interpretation of the results follows an earlier suggestion[4] that differences in isometric twitch contraction times of different muscles may be due largely to differences in intrinsic speed of shortening and that differences in P_t/P_o, or P_t as kg/cm^2, may result mainly from differences in the degree of activation of single muscle fibres

PATHOLOGY

Solubilization of Human Leucocyte Membrane Isoantigens

Isoantigens, thought to be important as histocompatibility antigens, have been identified on membranes of human cells by serological techniques[1] In order to interpret serological studies of histocompatibility antigens in terms of an understanding of the molecular representation of gene information, the isoantigens must be obtained in a suitable state for detailed chemical analysis Preparation of soluble isoantigen in relatively low molecular weight form would be an important step in this direction

Such an advance would also be relevant to efforts to achieve specific immunological tolerance of human tissue grafts Tolerance in animal systems has been difficult to induce across major histocompatibility loci when crude tissue extracts were used as antigens Previous studies, however, have indicated that tolerance can be induced to relatively pure, soluble protein antigens[2] During continuous work on transplantation immunology, we have investigated techniques that might yield human isoantigen in a soluble form

Methods for preparation of quantities of soluble human isoantigens have not been reported previously Mouse H-2 isoantigens, however, have been solubilized from cellular membranes in various ways[3-7]. In a very efficient proteolytic procedure, the enzyme papain was used to solubilize murine H-2 isoantigens When further purified (about 200-fold) by a combination of column chromatographic and electrophoretic techniques, the murine H-2 isoantigens were found to have the chemical characteristics of glycoproteins (85 per cent protein, 10–12 per cent neutral and amino sugar) and a molecular weight of the order of 70,000 (ref 8) In the present work, the method of papain digestion has been extended to the preparation of soluble, membrane-free human leucocyte isoantigens

Continuous cultures derived from human lymphoid tissue have been shown, in our laboratory, to possess a wide range of human leucocyte isoantigens Cell lines selected for preparation of isoantigens were *RAJI* and *RPMI*-4265 These two cell lines show different patterns of reactivity with a panel of human leucocyte isoantisera

Isoantigens were identified and quantified in the crude membrane and soluble preparations by a radioisotope release cytotoxicity technique modified to an inhibition assay[9] Quantitation was expressed as the reciprocal of the dilution of the various preparations necessary to inhibit 50 per cent of the cytotoxic reaction Antisera used to detect these isoantigens include a broadly specific antiserum, Iochum, which reacts with lymphocytes of 96 per cent of a normal donor panel and eight isoantisera of more limited specificities (Pinquette, Storm, Anderson, Kessler, T-155, T-53, Cutten, T-106) known to detect different genetically determined leucocyte isoantigens (Serum Bank, Transplantation Branch, National Institute of Allergy and Infectious Diseases, National Institutes of Health)

Crude membrane preparations were made by freezing and thawing 10^9 tissue culture cells in 12 ml of 0 14 M NaCl The cells and cellular debris were spun out at 1,500g (International centrifuge, *PR*-2) for 20 min at 4° C and the supernatant was collected The cells and cellular debris were washed for 10 min at 4° C in a stepwise fashion with solutions of decreasing concentration of NaCl (0 14 M–0 01 M NaCl). Cells and debris were removed after each wash by centrifugation Washing was discontinued when the supernatants were no longer turbid (usually about 0 01 M NaCl) The pooled supernatant solutions were centrifuged (Spinco *L*-2, 40 rotor) at 80,000g for 90 min and the resulting pellet suspended in distilled water at a concentration of 10–15 mg of protein/ml All protein determinations were by the method of Lowry[10] Crude papain II (Sigma Chem Co , St Louis, Mo) was dissolved in 0 05 M *tris* Cl–0 14 M NaCl buffer (pH 8 4) and stabilized with cysteine HCl at a final concentration of 0·01 M The papain solution was added to the crude membrane preparation to give several ratios of concentration. The ratio of 2 mg enzyme to 1 mg membrane protein was found to be particularly useful The release of protein and isoantigenic activity from the membrane was time dependent (Fig 1) Recovery of

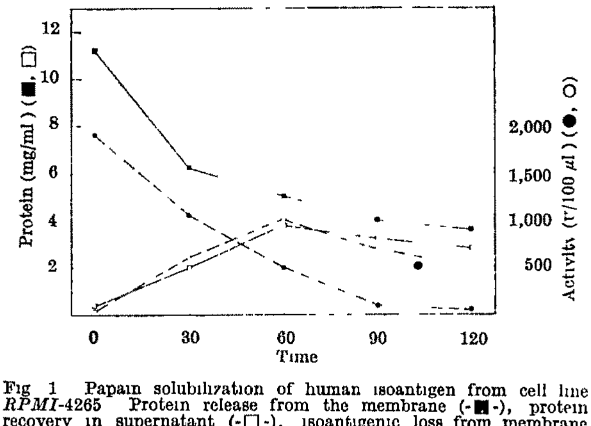

Fig 1 Papain solubilization of human isoantigen from cell line *RPMI*-4265 Protein release from the membrane (-■-), protein recovery in supernatant (-□-), isoantigenic loss from membrane (- - ● - -), isoantigenic recovery in the supernatant (- - ○ - -) Isoantigenic activity determined by the polyspecific antiserum, Iochum activity in the supernatant solution reached a maximum after 60 min of incubation at 37° C Isoantigenic activity in the supernatant decreased thereafter, indicating probable degradation by the enzyme

Recovery of isoantigenic activity in the soluble form was found to be 45–50 per cent of the total membrane activity in experiments with four preparations from two cell lines Inactivation of papain by iodoacetic acid (0 01 M final concentration) at time zero or incubation without enzyme resulted in release of less than 2 per cent of the activity This was not increased by adding 0 01 M cysteine alone These findings indicate that the antigen release shown in Fig 1 is a result of activity of the added enzyme preparation

The solubilized material was precipitated and concentrated by the addition of saturated ammonium sulphate solution (pH 7 6) to a final concentration of 75 per cent (ammonium sulphate at concentrations of 25 per cent and 50 per cent caused no visibly detectable precipitate) The solution was incubated for 30 min at 37° C and 18 h at 4° C The resulting precipitate was separated by centrifugation at 40,000g (Spinco L-2, 40 rotor) for 30 min at 4° C, dissolved in *tris* saline buffer (pH 8 4) and dialysed against this buffer at 4° C for 18 h An average of 17 per cent of the total protein and 67 per cent of the isoantigenic activity was recovered by ammonium sulphate precipitation of three enzyme-solubilized isoantigen preparations from each cell line

The solubilized material was further fractionated by chromatography on a column of 'Sephadex G-150' (Fig 2) Although at least four major protein peaks are evident, isoantigenic activity was found mostly in tubes 23–26 The isoantigenic activity was thirty times greater than the protein content in tubes 23–26 when compared with the starting material

The pattern of elution indicates that most isoantigenic activity is associated with molecules of 60,000–70,000 molecular weight if the membrane proteins separate chromatographically in a similar fashion to three proteins (ovalbumin, chymotrypsin and gamma globulin) which were used to calibrate the columns Some isoantigenic activity was evident in the excluded fraction of the first peak. It has not yet been determined whether this isoantigenic activity is associated with a different substance than the smaller molecular weight fraction, or whether it represents a larger material from which the smaller molecular isoantigens arise by enzyme action Two solubilized preparations from each cell line were fractionated on the same column of 'Sephadex G-150' Identical elution patterns were found for each preparation

Fractions were screened for isoantigen content by the polyvalent antiserum, Iochum Subsequently, six additional antisera, reacting with different isoantigens, were used to determine the presence of specific isoantigens in the various fractions These studies (not illustrated) indicated that the isoantigen molecules have similar but not necessarily identical distribution on gel-filtration chromatography.

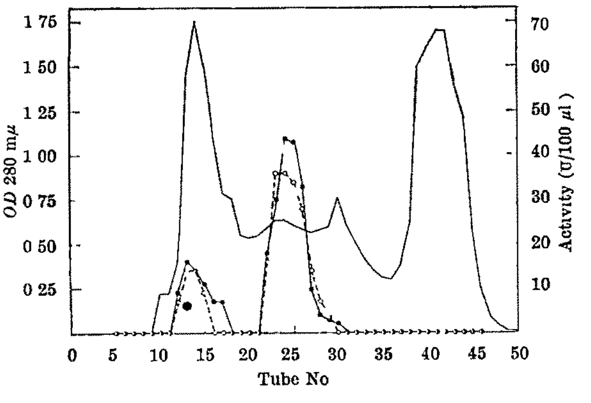

Fig 2 Gel-filtration ('Sephadex G-150') of papain solubilized human isoantigen Starting material was the $RAJI$ cell line Protein OD 280 mμ (—) Isoantigenic activity in units per 100 μl as detected by a polyspecific antiserum, Iochum (—●—), and an antiserum specific for LA-3 (Storm) (- - O - -)

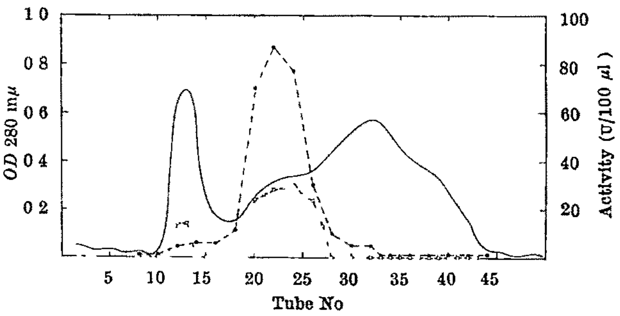

Fig 3 Chromatographic comparison of solubilized human and mouse isoantigens 'Sephadex G-150' gel-filtration of combined human ($RAJI$) and mouse ($C57Bl/6$) isoantigens obtained after papain treatment and 75 per cent sulphate precipitation Protein OD 280 mμ (—) Isoantigenic activity in units per 100 μl as detected by mouse antisera (H-2 5) (- - ● - -) and human isoantisera Storm (LA-3) (- - □ - -)

The elution pattern of human isoantigenic activity is similar to that found with papain solubilized mouse H-2 antigen[8] Human and mouse isoantigens solubilized by papain were directly compared by applying a mixture of soluble isoantigenic material from $C57Bl/6$ (H-2^b) mouse spleen cells and from human lymphoid cells on a column of 'Sephadex G-150' The elution pattern (Fig 3) demonstrates that human isoantigenic activity and mouse H-2 activity have similar chromatographic properties on 'Sephadex G-150' The observation that this enzyme releases molecules of similar molecular weight having known histocompatibility determinants (H-2) in the mouse and inferred histocompatibility determinants in man indicates that these components may have a similar structure in both species These results show that soluble human leucocyte isoantigens can be obtained in quantity both for biological studies (immunogenicity, immune tolerance) and for detailed chemical investigations.

RADIOBIOLOGY

Low *p*H of Irradiated Sucrose in Induction of Chromosome Aberrations

SEVERAL reports have dealt with the deleterious effects on biological objects of irradiated sugars, or foods containing them Some people have even implied possible harmful consequences as a result of consuming these irradiated products Because current research programmes involve the use of radiation as an agent for preserving food, some of the reports should be further investigated to establish clearly the incidence, nature and conditions in which deleterious effects are induced We are therefore studying damage to chromosomes in the root tip of *Vicia faba* caused by treatment with irradiated sucrose solutions, one of the subjects included in a report by Holsten, Sugii and Steward[1]

Moutschen and Matagne[2] found that the low *p*H of irradiated glucose solutions caused "sticky" bridges and chromosome clumping, and therefore adjusted such solutions to *p*H 6 before treating root tips for chromosome studies In our early experiments, we also noted the influence of *p*H on the extent of chromosome aberration Some reports of chromosome aberrations caused by irradiated sugars and other products have not provided information concerning the *p*H of the treatment substances, and the reported results may therefore be misleading For this reason we report here the results of two experiments on the influence of *p*H on the incidence of chromosome abnormalities caused by treatment with irradiated and non-irradiated sucrose solutions

Primary roots of seedlings of *V. faba* cultivar 'Bell' were used In both experiments, root tips were treated with 2 per cent sucrose solutions irradiated with 2 Mrad of gamma radiation from cobalt-60 at a rate of 5 5 Krad/min Controls were non-irradiated 2 per cent sucrose solutions, which, at their normal *p*H of 6 0, induced fewer abnormal anaphases than did water controls and no more than appeared in untreated root tips De-ionized, glass-distilled, filter-sterilized water was used for all solutions Common buffers were tested for possible use in *p*H adjustment they were harmful to root growth and did not counteract the sticky chromosome effect, as reported also by Moutschen and Matagne[2] The *p*H of all solutions was therefore adjusted with either KOH or HCl Root tips of the twelve seedlings/treatment were fixed immediately after treatment, and the terminal 1 mm of each was subsequently squashed in propionocarmine For each point on the curves, several hundred anaphases were scored.

In the first experiment, the period of treatment was 4 h Test solutions were adjusted to form a series of *p*H from 3 0 to 7 5, progressively increasing by 0 2 units between *p*H 3 0 and 4 0 and by 0 5 units between *p*H 4 5 and 7 5 Because atmospheric conditions can cause the *p*H of unbuffered solutions to drift, each irradiated sucrose solution and its control were adjusted consecutively to the same *p*H and seedling roots were immersed immediately

The *p*H of the solutions changed during treatment, evidently a result of root metabolism The root hairs seem to be particularly active in the *p*H changes When only the regions below the root hairs were immersed in solutions of low *p*H, the increase in *p*H after 4 h was considerably less than when the solutions covered the root hair zone Similar changes of *p*H occur in plant tissue or organ culture (for example, Gautheret[3]), the cells shifting the *p*H toward the most suitable value for growth Thus in irradiated solutions adjusted before treatment to a *p*H below 5 0 the *p*H increased during treatment The *p*H of similar solutions adjusted above 5 0 decreased The same applied to control solutions, but the point below which increase and above which decrease in *p*H occurred was *p*H 6 The difference in reactions of the irradiated and control solutions presumably resulted from strong buffering action of one or more acid components of irradiated sucrose This was confirmed in duplicated titrations of the two types of solution. A 2 per cent solution of sucrose which had a *p*H of 3 3 after irradiation (2 Mrad) was titrated against a control solution adjusted to *p*H 3 3 with HCl Five times as much 0 06 N NaOH was required to neutralize the irradiated solution

Because of changes in *p*H of the solutions during treatment, the mean of the readings taken before and after treatment was used in plotting curves The simple mean may not reflect precisely the conditions during treatment, but for the purpose of these studies it has been found adequate Small differences in *p*H changes in replicate treatments together with the greater change in *p*H of the control solutions account for the irregular spacing of points on the curves in Fig 1, and also for failure of most points on the irradiated sucrose curve to coincide in *p*H with points on the control curve Three complete replicate experiments were performed, and for certain initial *p*H values more than three replicates were run in order to obtain identical *p*H means for statistical analysis by the *t* test

Results of the first experiment show that when the *p*H of the solutions was between 4 6 and 7 2, no more chromosome aberration was caused by irradiated than by control solutions (Fig 1) At *p*H values lower than 4 6, percentages of abnormal anaphases in root tips exposed to either control or irradiated solutions increased with decreasing *p*H. The degree of increase of aberrant anaphases was, however, higher in irradiated solutions The value of *p*H 4 6 is not an absolute, but only the value in the specific experimental conditions above which response to irradiated and non-irradiated solutions was the same The maximum percentage of abnormal anaphases attributable to irradiated sucrose occurred at *p*H 3 5 and amounted to 32 5, as determined by comparison of the curves as plotted on graph paper

In the second experiment, the *p*H of all sucrose solutions, both irradiated and control, was adjusted to 6 5 before treatment The only variable was duration of treatment, that is, 0, 4, 8, 12, 18 and 24 h Otherwise, the experimental conditions were the same as before The experiment was repeated three times The results (Fig 2) show that increased duration of treatment up to 24 h

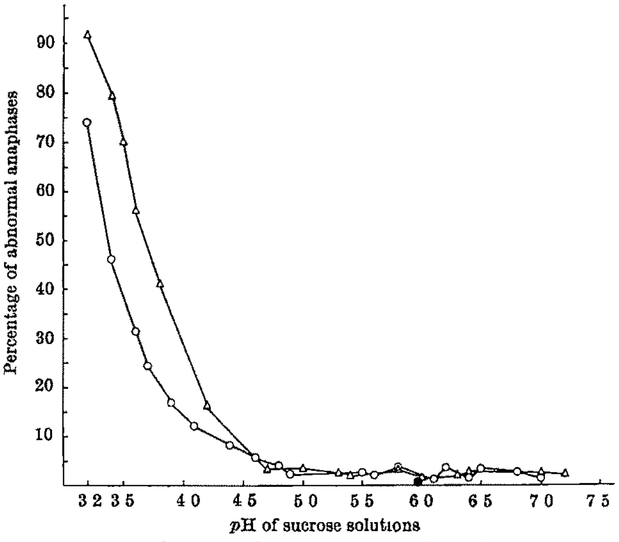

Fig 1 Effects of various values of *p*H of irradiated and control (2 per cent) sucrose solutions on the percentage of abnormal anaphases. Radiation dosage, 2 Mrads of gamma radiation from cobalt-60 Treatment period, 4 h △, Irradiated sucrose, ○, control sucrose The differences between percentages of abnormal anaphases in treated and control roots when solutions were at *p*H 3 4 were significant at the 1 per cent level, and at *p*H 7 0 were not significant at the 10 per cent level

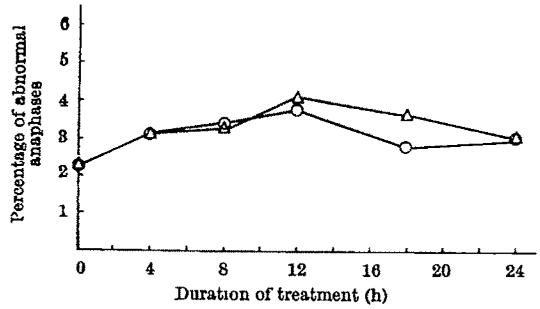

Fig 2. Effect of duration of treatment (0, 4, 8, 12, 18 and 24 h) on the percentages of abnormal anaphases when all irradiated and control solutions were adjusted to pH 6 5 before treatment Radiation dose and symbols for curves are the same as for Fig 1 Differences between percentages of abnormal anaphases in treated and control root tips at 12 and 18 h, respectively, were not significant at the 10 per cent level

when all solutions were adjusted to pH 6 5 caused no differences in response to irradiated sucrose.

The same types of chromosome aberrations appeared after treatments (24 h) with irradiated and control solutions Also, the proportions of specific types of aberration (spindle defects, fragments and bridges) were almost identical in the two samples of about two hundred anaphases each (unpublished data) The evidence from these studies thus points to low pH alone as the cause of mutagenic effects

The strong buffering in irradiated sucrose solutions may account for the higher incidence of abnormal anaphases from exposure to irradiated than control solutions The inability of root tips to raise the pH as much in irradiated as in control solutions of low pH means that root tips in irradiated solutions remain longer at pH values near the initial adjusted values than do those in control solutions The means of initial and final pH values therefore adequately express the differences in exposures of root tips to irradiated (or control) solutions adjusted to different pH values, but they are inadequate for comparing exposures to irradiated and control solutions having the same mean pH values This implies that the curves in Fig 1 should approximate each other more closely than they do

We thank Dr Noel Sommer for valuable criticism of the manuscript This work was supported in part by the US Atomic Energy Commission, Division of Biology and Medicine

MICROBIOLOGY

Degradation of 'Diazinon' by Synergistic Microbial Action

THE mechanisms and pathways involved in the degradation of pesticides have received more attention as efforts to define the extent of environmental contamination by these chemicals have increased. Complex interrelationships have been found between the soil microflora and organophosphate insecticides, such as 'Diazinon'[1-3] In the case of 'Diazinon', utilization of the chemical by an *Arthrobacter* sp. and a *Streptomyces* sp has been shown to alter the existing microbial population balance by stimulating a selective enrichment of these species[3] Labelled carbon dioxide was evolved when 'Diazinon' labelled on the C1 of the ethyl ester was incubated with a species of *Arthrobacter* for 24 h. Similarly, labelled carbon dioxide was given off when the same labelled insecticide was injected into soil which contained an unidentified microbial population We had been concerned with the pyrimidinyl ring of the 'Diazinon' molecule, and the possible differentiation of the degradative pathways associated with microbial metabolism by which the *Arthrobacter* and the *Streptomyces* that emerged as the predominant successive microfloral forms in soil treated with 'Diazinon' could attack the ring moiety of this compound

Both organisms were cultured in a mineral salts medium in which they could grow with 'Diazinon' as the primary source of carbon when the 'Diazinon' was solubilized in ethyl alcohol before being introduced into the growth medium Ring-labelled ^{14}C-'Diazinon' (specific activity 4 0 μCi/mg) was diluted in ethanol to give a net c p m of 200–300 in final dilution Cultures of the *Arthrobacter* and *Streptomyces* were collected after 18 and 96 h, respectively, to give comparable cell weights (40–50 mg wet weight) Cells were washed twice in sterile, distilled water and a third time in 1/15 M phosphate buffer, pH 6 5 The reaction mixture consisted of 20 ml of phosphate buffer, pH 6 5, 5 ml of washed cells in the same buffer, and 0 1 ml of ^{14}C-'Diazinon' in ethanol The reaction vessel was closed with a two-hole stopper, one hole an air inlet, the other carrying the carbon dioxide produced to a trapping tube containing 25 ml of 0·1 N $Ba(OH)_2$ The 'Tygon' tube leading from the reaction vessel to the carbon dioxide trap passed through a peristaltic pump which drew the gases from the reaction vessel into the trapping tube Incubation with labelled ^{14}C-'Diazinon' was maintained for 18 h, after which the precipitated carbonate was rinsed out of the trapping tube with sterile distilled water on to a filter disk. Aliquots of supernates from the reaction vessels and of the cell pellet were also transferred to individual filter disks. The disks were dried, placed on a planchette and the activity was measured in a windowless gas-flow counter No labelled barium carbonate was detected as the result of bacterial respiration On the basis of these results, it was concluded that the *Arthrobacter* sp previously reported to attack the side chain of the molecule was unable to completely metabolize the ring portion of the molecule

Similar results demonstrated that the *Streptomyces*, too, could not by itself convert the pyrimidinyl carbon to carbon dioxide (Table 1). When, however, both the *Arthrobacter* and the *Streptomyces* were incubated together, 15–20 per cent of the carbon-14 appeared as labelled $BaCO_3$ after 18 h, suggesting a synergistic relationship between these two organisms in attacking the pyrimidinyl portion of 'Diazinon'

Confirmation of these results was obtained when cultures of the *Arthrobacter* and of the *Streptomyces* were grown separately and together in a mineral salts medium in which carbon-14 ring-labelled 'Diazinon' served as the sole source of carbon. The contents of the flasks were collected after 7, 14 and 21 days, respectively. The cultures were centrifuged at 9,000 r p m. (g) for 10 min and the supernate was extracted three times with diethyl ether Cell pellets were washed and ground in a glass microhomogenizer and extracted, as were the supernates. Assays for degradation products were made by thin-layer chromatography, using as a solvent chloroform with 0 7 per cent ethyl alcohol and followed by autoradiography with Eastman no-screen X-ray film

Table 1 SYNERGISTIC METABOLISM OF RING-LABELLED ^{14}C-'DIAZINON' BY AN *Arthrobacter* AND *Streptomyces* SPP

Treatment	c p m *Arthrobacter*		*Arthrobacter* + *Streptomyces*	Control
		Streptomyces		
Cells after third wash	26 9	590 4	105 6	
$Ba^{14}CO_3$	0 0	0 0	44 1	0 0
Uninoculated control				202 6

All samples were counted to the level of 5 per cent significance above background Figures are corrected for background

Table 2 INCORPORATION OF SIDE-CHAIN AND RING-LABELLED ^{14}C-'DIAZINON' BY *Arthrobacter*

Incubated with	c p m Cells after three washings	$Ba^{14}CO_3$
Side-chain label	282 4	42 9
Ring label	325 6	0 0

Cells were incubated for 18 h Specific activity of the side-chain labelled 'Diazinon' was 3 21 µCi/mg, of the ring-labelled 'Diazinon' 4 0 µCi/mg Dilutions were made to give comparable initial activities

When the *Arthrobacter* and *Streptomyces* were incubated separately no change was evident in the 'Diazinon' molecule Both the 'Diazinon' in the supernatant as well as the material incorporated in the cell interior remained intact When, however, the *Arthrobacter* and *Streptomyces* were incubated together radical changes were evident After 7 days, only 6 per cent of the parent 'Diazinon' molecule remained, whereas 84 per cent was converted to one unidentified metabolite and 10 per cent to a second unidentified metabolite At 14 days, only 3 per cent of the parent 'Diazinon' remained, whereas metabolite I contained 83 per cent and metabolite II contained 10 5 per cent The parent compound was no longer detected at 21 days, while 86 per cent of the activity was in metabolite I and 14 per cent was present in metabolite II Although the precise identity of these two metabolites remains to be established, thin-layer chromatographic analysis with palladium chloride, a highly specific test for the P=S bond, has shown the presence of this group in both metabolites

Apart from chemical hydrolysis to the pyrimidinyl and phosphorothioate moieties, only carbon dioxide has been recovered as a product of the microbial degradation of 'Diazinon', although the test organism incubated with labelled material showed substantial incorporation of the entire molecule Data from a typical experiment with *Arthrobacter* are shown in Table 2 The absence from pure culture supernates of predicted intermediates ('Diazoxon', tetraethyl dithionopyrophosphate, tetraethyl monothionopyrophosphate, 2-isopropyl-6-mercapto-4-methyl pyrimidine, 6-hydroxy pyrimidine, diethylthiophosphoric acid) would suggest that a significant proportion of the 'Diazinon' molecule may be converted to stable cell constituents and so retained within the organism Cell fractionation studies are currently in progress to test this assumption

Most significant seem to be the indications provided by this study of a synergistic relationship between two organisms in the degradation of a pesticide molecule which neither can achieve by itself Such an interaction, though not to our knowledge previously cited for pesticides, is not uncommon in the soil and elsewhere[4-6]. Mutualistic relationships in the decomposition of cellulose have been frequently noted; a mixed culture is obtained from soil which actively decomposes cellulose whereas the individual cultures will not perform the same task[7]

Whatever the model which will be uncovered for the synergistic activity here reported, these investigations, though preliminary in nature, offer encouragement to the view that molecules hitherto considered recalcitrant to the attack of individual pure cultures of microbes may in fact be biodegradable under the synergistic assault of mixed naturally occurring populations

Filamentous Phages specific for the *I* Sex Factor

EVERY transmissible bacterial plasmid like a colicin (*col*) factor or a drug resistance (*R*) factor necessarily contains a sex factor responsible for its transmission by conjugation[1-3]. The conjugation bridge is likely to be a sex pilus[4] and examination of some eighty independent plasmids of various kinds isolated from Enterobacteriaceae has shown that only two types of sex pili can positively be identified and therefore that only two types of sex factor are probably present[2,3] These are typified by *F*, the well known sex factor of *Escherichia coli*, and by *I*, the sex factor of *colI* (refs 2 and 3) Phages specific for *F*-like sex pili have frequently been isolated and are of two kinds isometric RNA phages attaching along the length of the sex pilus and filamentous DNA phages attaching to the tip of the pilus[5] The morphological and antigenic characteristics of *F*-like and *I*-like sex pili are distinct[2], so it seemed very probable, because *F* phages do not attach to *I*-like pili, that *I*-specific phages existed These have now been isolated[2], using as hosts bacteria carrying de-repressed (*drd*) mutants of fi^- *R* factors[6], the sex factors of which are known to be *I*-like[2] Strains carrying these mutant *R* factors continually form sex pili and can therefore be used as indicators for the corresponding donor-specific phages

Plating of sewage on *E coli K*12 *drd* R^+ did not yield *I* phages, and so the following method of selection was devised with successful results *F* phages are known to plate on F^+ *Salmonella typhimurium* as well as on F^+ *Escherichia coli* Thus if the phage population of sewage was enriched by overnight incubation with *drd* R^+ *Salm typhimurium* and then plated on *drd* R^+ *Escherichia coli*, or vice versa, only *I* phages would be expected to plate, because the somatic antigens which provide the receptors for many phages differ in the two species In the event, several flagellar phages were unexpectedly isolated because these can adsorb to the flagella formed by the two hosts[7] Enrichment consisted of mixing 1 ml of untreated sewage, 1 ml of overnight culture of the enriching strain (either *Salm typhimurium M*385 or *Escherichia coli K*12 carrying the *drd* fi^- *R* factor, 144 or 64) and 9 ml of Oxoid Nutrient Broth No 2 After incubation overnight, the culture was centrifuged in an angle rotor at 650*g* for 15 min and the supernatant sterilized by filtration through a broth-treated asbestos–cellulose pad. Phage was titrated by depositing 0 02 ml drops from nine ten-fold dilutions on 2 5 ml overlays of 0 35 per cent agar previously inoculated with the indicator and poured on thick plates of Oxoid Blood Agar Base These were incubated overnight at 37° C Four indicators were used *M*385 R^+ and R^-, and *K*12 R^+ and R^-. Inspection of the incubated plates usually showed immediately whether a given plaque type was present on the R^+ but not on the R^- strain, and on *K*12 as well as on *M*385 The drop method is much to be preferred to counts in overlays poured in the usual way, because minute plaques stand out far more distinctly against the surrounding background

Ten independent samples of sewage were examined, of which two, from Billericay, Essex, and from Croydon, Surrey, yielded the *I* phages, *If*1 and *If*2 Both isolates were from samples enriched on *M*385 and plated on *K*12, enrichment on *K*12 followed by plating on *M*385 often

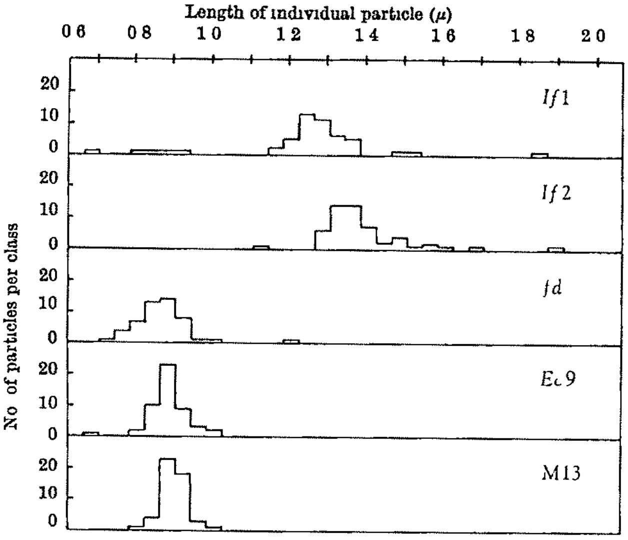

Fig 1 Distributions of lengths of individual particles of the *I* phages, *If*1 and *If*2, and of *F* phages, *fd*, *Ec*9 and *M*13

failed to give plaques of any kind and was abandoned Comparison of the R^+ and R^- plates of the same host showed that about 20 per cent of all sewage phages were restricted by the *R* factor Identification of the phages was greatly simplified by electron microscopy of material taken directly from plaques[8] and often showed immediately the site of attachment of the phage as well as its morphology

Particles of phages *If*1 and *If*2 occurred in large masses like those illustrated for the filamentous *F* phage, *Ec*9 (ref 9) The modal length of individual particles was about 1 3μ (Fig 1), which is markedly longer than the filamentous *F* phages *fd* (ref 10), *Ec*9 (ref 9) and *M*13 (ref. 11) There was no indication in the electron micrographs, such as a central line down the particles or the appearance of split ends, that each particle consisted of a loop twisted on itself as described for phage *fd* (ref 12) Both the *I* phages contained single-stranded DNA, judging from staining with acridine orange[13], with and without previous treatment with DNase or RNase[14] Aqueous suspensions of filamentous *F* phages are exceptionally resistant to inactivation by heat[9,15] Phage *If*1 was also considerably more resistant than a *T* phage[16] although it was slightly less resistant than phage *Ec*9 (Fig 2) Nevertheless, it is evident that heating, for example, to 82° C for 20 min, might provide an additional means for selecting filamentous phages of all kinds

The plaques formed by both *I* phages were usually about 0 5 mm in diameter, even when extremely soft overlays of 0 35 per cent agar were used The most distinct plaques were obtained on Oxoid Blood Agar Base the addition of 0 01 M $MgCl_2$ or 0 005 M $CaCl_2$ was without effect When plaques were exceptionally well defined, infected bacteria produced plaques with a central dot of phage-resistant bacterial growth, whereas free phage formed clear plaques When plaques were less distinct, phage mutants forming clearer plaques could be distinguished One-step growth curves of phage *If*1 resembled those obtained with filamentous *F* phages in that the rise period seemed to be indefinitely prolonged After a latent period of 35 min, the titre of free phage increased at least 1,000-fold at a constant rate during the next 2 h, presumably reflecting the continuing secretion of progeny particles by the infected organisms[17] The host range of the *I* phages has already been described in detail[2,3] and is principally determined by their ability to adsorb tip-to-tip to the sex pili of the test bacteria Thus *I* phages adsorb to the *I*-like pili determined by most *fi*⁻ *R* factors, *colI* and the *I* sex factor associated with *colEla*[18,19], but not to the *F*-like pili determined by *F*, F_0-*lac* and *fi*⁺ *R* factors[2,3]

Table 1 RELATIVE *K* VALUES IN CROSS-NEUTRALIZATION TESTS

	Phage				
Serum	*If*1	*If*2	*M*13	*fd*	*Ec*9
*If*1	1	1	<0 001	<0 001	<0 001
*If*2	1	1	<0 001	<0 001	<0 001
*M*13	<0 001	<0 001	1	0 25	0 25
fd	0 1	0 1	0 2	1	0 6
*Ec*9	0 1	0 1	0 4	1	1

K values estimated from per cent survival after exposure to serial dilutions of antiserum for 60 min at 37° C

Neutralizing antisera with *K* values of about 10^3 were readily produced in rabbits by five intravenous injections of 10^{10} particles during a fortnight These sera, and also antisera to the three filamentous *F* phages, *M*13, *fd* and *Ec*9, were used to determine the degree of antigenic relationship between the two groups of phages (Table 1) Neutralization tests showed that *If*1 and *If*2 behaved identically, as did *fd* and *Ec*9 Anti-*I* sera failed to neutralize any of the *F* phages, although the *I* phages were neutralized by anti-*fd* or anti-*Ec*9 but not by anti-*M*13 There is thus an anomaly in that the *I* phages evidently shared a common antigen with phages *fd* and *Ec*9, yet anti-*I* sera did not neutralize these phages This asymmetrical finding might arise either because the homologous antibody was provoked only by the *F* phages or because the antigen of the *F* phages could unite with the homologous antibody without loss of infectivity Agglutination tests were therefore performed on a microscopic scale by leaving a mixture of 1/40 antiserum and phage on the microscope grid for 1 h at room temperature, when the drops were then stained with uranyl acetate. Although no neutralization occurred, agglutinated phage particles were seen coated with globulin molecules which held the aligned particles some distance apart; whereas particles aggregating spontaneously were closely opposed The results of these tests, which were necessarily only semi-quantitative, showed that anti-*I* sera contained globulin reacting to moderate titres with phages *fd* and *Ec*9 and to a slight extent with *M*13 At this stage it therefore seems that antigenic relationships exist between the *I* and *F* filamentous phages which are not fully revealed by neutralization tests The two *I* phages are closely related

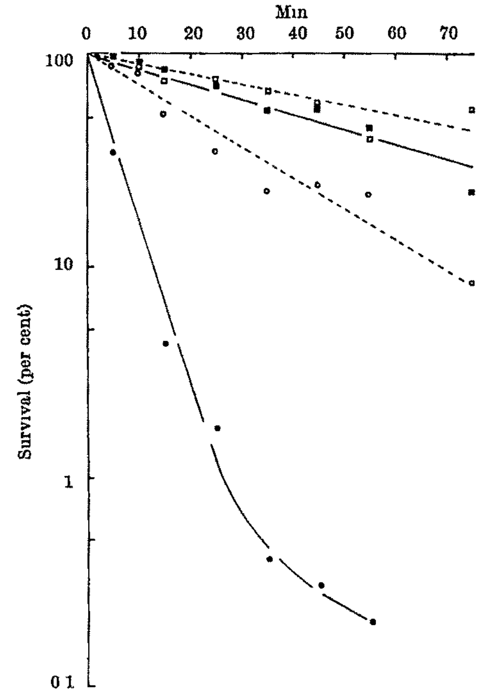

Fig 2 Thermal inactivation of phages *If*1 (●, ○) and *Ec*9 (,■ □) at 88° C (solid points, continuous curve) and at 82° C (open points, dashed curve) The phages were mixed in broth at a concentration of 10^5/ml each, heated, and counted separately on *drd* R^+ and on F^+ indicators

as are *fd* and *Ec9*, whereas *M*13 seems to differ considerably from both groups

In general, the filamentous *I* phages bear a marked resemblance to those attacking *F*-like pili, which suggests a common origin No isometric *I* phages have yet been isolated, although they should have been obtained by the present method of selection because we have used it to isolate isometric *F* phages One *F*-related plasmid, F_0-*lac*, is known to determine *F*-like pili which adsorb filamentous but not isometric *F* phages[2]. It may be that the fi^- *R* factors so far used for the isolation of *I* phages are similarly unable to propagate isometric *I* phages

We thank Dr R Dettori and Dr H Hoffmann-Berling for phages and antisera, and Dr H Williams Smith for providing the material from which phage *If*1 was isolated

GENETICS

Unusual Distribution of Red Cell Acid Phosphatase among Aborigines of Australia

THE Australian Aborigines are an interesting population for the study of human variability due to inherited characteristics The first study of their blood groups was published in 1922 (ref 1) and many extensive surveys have since been undertaken More recently discovered polymorphic characters, including the serum haptoglobins, transferrins, gamma globulins and group specific types, have also been investigated, and the results have been reviewed[2–4]. There is, however, no published information about the distribution of red cell acid phosphatase types among the aborigines and the study reported here was undertaken primarily to provide the information

Blood samples were obtained from the subjects at Darwin and Alice Springs in the Northern Territory and at Cairns in Queensland by staff members of the Commonwealth Health Laboratories Because of the interest which they have provided, many Australian aborigines have been subjected to venepunctures for research purposes. There is now some reluctance to approve the collection of blood for surveys of individual gene markers The problem was overcome in this work by using blood samples which had been collected for clinical pathology investigations Serum for the tests had been removed from all samples and the investigation described here was performed on the residual clots There is no reason to suggest that this selection was in any way related to the genotypes of the subjects Obviously, this material would not be suitable for an extensive survey of both red cell and serum gene markers, but it proved convenient for the test in this survey The samples were kept in a refrigerator after collection, transported to Sydney by air and were tested within 10 days of collection

The red cell acid phosphatase types were determined with minor modifications[5] by the starch gel electrophoresis and staining technique described by Hopkinson, Spencer and Harris[6] The phenotypes were classified using the nomenclature published elsewhere[7] Briefly, the enzyme types formerly called A, B, AB, and so on, have been designated PHs^A, PHs^B and PHs^{AB}, and so on, and the allelic genes PHs^a, PHs^b, and so on, where *P* stands for the gene locus in *Homo sapiens* (*Hs*)

The results are shown in Table 1 Only three phenotypes controlled by two alleles, PHs^a and PHs^b, were found The frequency of the PHs^b is higher than has been observed in any other population. This gene is the commonest in all populations studied so far[8], but the highest frequency previously recorded was 0 805 in a group from the Tristan da Cunha Islands[9]

Table 1 RED CELL ACID PHOSPHATASE IN AUSTRALIAN ABORIGINES

Phenotype	Cairns No observed	Cairns No expected	Darwin No observed	Darwin No expected	Alice Springs No observed	Alice Springs No expected
PHs^A	0	0 2	0	0 1	0	0
PHs^{AB}	8	7 7	5	4 8	0	0
PHs^B	84	84 1	148	148 1	26	26 0
Total	92	92 0	153	153 0	26	26 0
Gene frequency						
PHs^a	0 044		0 016		—	
PHs^b	0 956		0 984		—	

The high frequency of PHs^b among the Australian aborigines could be the result of selection or of the founder principle If selection has operated over the centuries or millennia the gene PHs^b must have been favoured to the extent that the genes, PHs^a and PHs^c, were at least partially eliminated Alternatively, the Australian continent may have been populated by a group which by random chance had a high frequency of PHs^b. The recently restated trihybrid theory[10] involves three successive migratory waves from different parts of Asia with unequal mixing in different geographic areas of Australia. If this theory is correct, selection after arrival seems more likely than the possibility that all migrating groups had the same high gene frequency

I thank the staff members of the Commonwealth Health Laboratories in Darwin, Northern Territory, and in Cairns, Queensland, for the blood samples.

Fossil Vertebrates

Edited by Colin Patterson and P H Greenwood Pp v+260 (London Academic Press, Inc (London), Ltd., New York Academic Press, Inc , 1967) 70s , $8 60

THE presentation of collections of research papers to eminent scientists on their retirement is a happy custom This volume honours Dr Errol White, until recently Keeper of Palaeontology at the British Museum (Natural History) and President of the Linnean Society It contains papers, mostly on aspects of palaeo-ichthyology, by vertebrate palaeontologists from many countries in both Europe and North America, and gives abundant evidence of the respect and affection in which he is held

In 1950 White showed how the changes in their fish faunas could be used to classify the Lower Devonian strata of the Welsh borderland, and later showed that this scheme was valid also for Western Europe Obruchev and Karatajūte-Talimaa now show that it is similarly valid for Eastern Europe, while Dineley demonstrates that it can even be used to correlate the Knoydart faunas of Nova Scotia

Several contributions deal with different aspects of growth and ossification One present controversy is as to whether the carapace of the earliest fish consisted of a small number of large plates (a point of view to which a paper by Tarlo gives further support) or of a large number of small tesserae In an elegantly argued paper, Westoll points out the difficulties involved in accepting either of these extreme positions, and suggests that the different patterns may result from variation in the extent to which the larger, deeper plates may be exposed or concealed by the development of more superficial tesserae Another controversy concerns the methods used to identify and homologize the dermal skull bones of fish and tetrapods Parrington argues strongly that these must be based on the overall relationships of the bones to one another and to underlying structures, accepting that minor variations will occur As he points out, belief in complete uniformitarianism leads to surprising anomalies and the supporting arguments are, in some cases, internally inconsistent A very useful paper by Schaeffer briefly reviews the structure and development of osteichthyan vertebrae He shows that, although the arch components and centra are clearly homologous throughout the Osteichthyes and tetrapods, the latter differ in the resegmentation of the sclerotome and in the fact that the notochordal sheath is not involved in the formation of the centrum

Aspects of fish evolution are discussed by Jarvik and by Gardiner Jarvik demonstrates that the lower jaw of early Dipnoi was already very dissimilar from that of other fish and, like many other aspects of dipnoan anatomy, suggests that the group diverged at a very early date Gardiner describes the way in which modifications in the structure and relationships of the preopercular bone have contributed to the improvements in the mechanism of feeding and gill ventilation in the actinopterygians

These and other contributions together make up a volume which any workers concerned with the anatomy, palaeontology, taxonomy or stratigraphy of fish will find both informative and thought provoking The editors must be congratulated on an almost error-free text, and

ACROSS THE BERING STRAIT

The Bering Land Bridge

Edited by David M Hopkins Pp xiii+495 (Stanford, California Stanford University Press, London Oxford University Press, 1967) 176s net

THIS book consists of twenty-two papers with an introduction and synthesis by the editor The book is related to, but is not a record of, the symposium entitled "Late Cenozoic History and Environments of the Bering Land Bridge" held at the Seventh Congress of the International Association for Quaternary Research (INQUA) Eight of the papers included in the book were not given at the symposium and two of the papers read at the symposium are not included in the book The papers, by American, Canadian, English, German, Icelandic and Russian specialists, provide data and hypotheses on the geology, geomorphology, oceanography, palaeontology, biogeography, archaeology and anthropology of the areas around and under the Bering and Chukchi Seas

Some of the evidence presented in the book has been derived from areas very far from the Bering Strait The arrival of molluscs of Pacific boreal ancestry on the north shores of Iceland more than three million years ago, and the development of Aurignacoid industries in Eurasia, are both significant in the interpretation of the events that took place in Beringia The timing of these events also requires a comparison of Quaternary chronologies developed in different parts of the world The stratigraphy and chronology of the last 70,000 years in North America, Europe and Siberia is shown to be sufficiently well known to enable useful correlation However, the period one million to three million years B P is less well known The record of ten glaciations, the first occurring possibly between 2 4 and 3 0 million years ago, in northern Iceland is stated as probably representing a minimum estimate of the total number of important world-wide Pleistocene glacial cycles, and therefore the Bering Land Bridge may have been renewed as many as ten times by glacio-eustatically lowered sea level during the Pleistocene

As a collection of research papers this book has the disadvantages of a certain amount of repetition of material, duplication of bibliographies and lack of standardization of chronological nomenclature Although most of the authors have published most of their material elsewhere, the editor is to be complimented on bringing together contributions from many disciplines and in several languages Most of the authors have also succeeded in orientating their papers to highlight the central theme, namely, the nature and significance of a land connexion between Eurasia and North America The editor has had a very difficult task in writing his synthesis and he has accomplished it with clarity and confidence It may well be that the major contribution of this book is to highlight outstanding problems and to indicate the great value of the interdisciplinary approach

R J PRICE

POLYCHAETA IN AFRICA

A Monograph on the Polychaeta of Southern Africa

By J H Day Part 1 Errantia Pp viii+1–458 Part 2 Sedentaria Pp 459–878 (London British Museum (Natural History), 1967) 300s the two parts

THIS important and scholarly work has a far wider value than its title would suggest There have been relatively few monographs on the polychaete annelids and none has so far dealt with southern Africa. It is welcome not only in covering this region for the first time in this way, but also for the keys provided, which apply to families and genera everywhere.

The work is divided into two easily handled volumes, one dealing with the Errantia, the other with the Sedentaria. This is convenient for the present purpose although arbitrary. There is a useful and concise introduction and description of methods for collection and examination, which make these books easily usable by the beginner. With the beginner also in mind, there are illustrated keys to the families, and these, together with the initial explanations and instructions for using the monograph with a map of the main localities, are repeated at the beginning of the second volume, so that each can be used without reference to the other. To avoid confusion page numbers run on, the second volume starting at page 459. I like this arrangement, for it simplifies the index. The illustrations are throughout clear and helpful. Some of those of whole worms in the initial key to families (Fig. 0.2, 4–6, 9) are small, and though recognizable, I wonder if they would really be helpful to a beginner. The initial dichotomy of this key is not always as easy as a novice might think. The chronological list of principal references is both useful and interesting to the more general taxonomist, and the arrangement of authority, province collected and depth range relating to each species described is clear and concise.

The order of families is the conventional one. There is a useful definition of every family, each definition being followed by a list of records from southern Africa (south of 20° S.), biological notes, chief diagnostic characters, and a key to genera. These keys and the comments on the diagnostic characters are what workers elsewhere will find useful. Genera not found in southern Africa are marked with an asterisk, and are not thereafter defined. To compile such a work is a prodigious task and it is perhaps impossible without minor errors. These are few and they in no way detract from the accuracy and usefulness of the work. *Tachytrypane* is defined (page 580) although it does not occur in the region, *Pseudoscalibregma* (page 585) should be asterisked in the key, and Apistobranchidae is mis-spelt in the initial key to families. I also found the running title "Cirratulidae and Heterospionidae" (pages 499–517) confusing in that the latter family has not been recorded from this region and hence receives only brief mention. There is a useful glossary at the end of the second volume, and a bibliography. The work includes eighteen new names which are noted in bold type in the index.

Professor Day can only be congratulated for achieving both a definitive monograph on the polychaetes of southern Africa and at the same time providing a work which will be of major value to those collecting in other parts of the world. In spite of the high price, these volumes should find a place on the shelves of libraries of all zoology departments. The trustees of the British Museum must also be complimented on its production, and their printers, Messrs Eyre and Spottiswoode, of Portsmouth, for the very fine job of printing they have done.

R. PHILLIPS DALES

HUMAN HISTOLOGY

Human Histology

Second edition. By Bruce Cruickshank, T. C. Dodds and Dugald L. Gardner. Pp. viii+359. (Edinburgh and London: E. and S. Livingstone, Ltd., 1968.) 84*s*. net.

PRECLINICAL medical students fall into three principal categories and, because their aims in studying medicine are different, the books that they choose, or from which they will derive most benefit, are naturally rather different. The vast majority are anxious in their preclinical days to equip themselves with a sound enough background knowledge of anatomy, physiology and biochemistry to enable them to understand what is going on in the various pathological cases with which they will come into contact and later have to treat. Second, there are a few who not only want to know what is known, but to know how it came to be known, and to be convinced by the evidence that the so-called knowledge is genuine. Many of these are further motivated to enquire more deeply into and to question the "facts" presented to them. Third, there are also a few who aim to acquire only the minimum knowledge of preclinical material necessary to ensure their place at a hospital where they will then learn in "the practical way".

This book is clearly directed towards the vast majority. It is a very clear, dogmatic account of the various tissues and cells of the body as they are at present understood and interpreted. It is very well illustrated with colour photographs, electron micrographs, and with black-and-white figures in various forms. For the non-enquiring mind it gives an excellent picture of human histology. The student with the enquiring mind will not, however, be satisfied with it, though he will certainly find it very useful as a revision book. It does nothing to encourage the reader to evaluate evidence. It does not sufficiently indicate the complexities of tissue interactions or portray cells as living, functioning and adapting entities. The restriction to human tissues, while it may have certain practical advantages, artificially isolates man from other animals and deprives the student of any sense of evolutionary continuity or of species differences. Both of these concepts are of fundamental importance in relation to the evaluation of evidence from experiments on animals, and indeed to the proper understanding of events in the human body.

There are some curious errors, for example, in the chapter on the eye, pathological training has clearly been more influential on the authors than the study of Latin. Bacillum (later, bacillus) was a rod long before it became a bacterium. The macula lutea is yellow because it contains xanthophyll, not because its centre is free of blood vessels. The fovea centralis is within the macula lutea—not the reverse.

Medicine would get on better if histology were more concerned with what cells and tissues do than with what they look like.

E. N. WILLMER

VOLCANIC PAST

The Eruption of Hekla in Historical Times

A Tephrochronological Study. By S. Thorarinsson. Pp. 183+12 plates. (Reykjavik: Visindafelag Islendinga, 1967.) n.p.

TEPHROCHRONOLOGY, or volcanic ash chronology, is a method of study of volcanic areas which depends on the fact that the ash thrown out by a volcanic explosion is dispersed over a wide area, and the resulting ash layer is sensibly of the same age over its whole extent. A succession of such ash layers represents a time sequence relative to which other events, such as the outpouring of lava flows, the retreat of glaciers, or the abandonment of human habitations, can be dated.

A few tens of volcanic eruptions take place in the world each year, but few are studied scientifically and the volume of available data is still quite small. Tephrochronology makes available for study an enormously greater number of eruptions than would occur during one's life-time, and offers the best hope of rapidly acquiring a comprehensive knowledge of volcano behaviour.

This book is one of the most comprehensive accounts yet published on the activity of a volcano over a long period of time, covering as it does a time-span of 1,000 years and a succession of fourteen substantial eruptions Well written (as one has come to expect of the author), it is a remarkable chronicle which, besides scientifically documenting the eruptive products, delves deeply into contemporary Icelandic writings It is illustrated with twenty-eight text-figures, twelve plates, and a 1 120,000 geological map of Hekla and its surroundings (as it was before the 1947–48 eruption) A chapter on the petrology of Hekla's products, written by Jens Tomasson, is included

Isopach maps are compiled for six ash layers, and from them the volume of each ash-fall is computed Taken in conjunction with the volumes of associated lava flows, this gives a figure for the productivity of Hekla, meaningful because it is based on the record of a period of time long in relation to the average repose time between eruptions Chemical studies show that most of the eruptions started with an explosive phase erupting relatively acid pumice, and the composition of the erupted products then became more basic, moreover, the longer the repose period since the preceding eruption the greater was the acidity of the initially erupted material Studies of this kind should have a profound influence on petrogenetic theory which, at present, tends to neglect the time factor

I would have liked to see some data on the grain-size and other textural features of the ash deposits—an opportunity has been lost here to make a notable contribution in this much neglected field—and some more information on the lavas of Hekla The virtual omission of the 1947–48 eruption is excusable, as it is well documented by other publications of which this book is one of a series

Thorarinsson's book is essential reading for all who are interested in volcanology It is a basic work on tephrochronology, written by the pioneer of the method, and is relevant also to the archaeologist and climatologist, or whoever is concerned with the chronology of the last few millennia, nor should it be spurned by the general reader, for it gives an insight into the sociological impact of eruptions from the volcano that was for long believed to be the location of hell

G P L WALKER

AROUND OLLERTON

Geology of the Country around Ollerton

By W N Edwards With contributions by J Phemister and R K Harrison (Explanation of One-Inch Geological Sheet 113, New Series) Second edition (Natural Environment Research Council—Institute of Geological Sciences Memoirs of the Geological Survey of Great Britain—England and Wales) Pp x+297+10 plates (London H M Stationery Office, 1967) 55*s* net

THE principal purpose of this new edition of the Ollerton memoir is to revise the account of the underground geology made possible through the intense search for coal by the National Coal Board and for oil by British Petroleum Much of the new information has been derived from bore-holes, and the main author of this work, Mr W N Edwards, has skilfully brought together these data with observations made by the Geological Survey's officers and a wealth of rock description provided by the petrology section of the Institute of Geological Sciences led by Dr J Phemister and Mr R K Harrison Some of the results obtained during the search for oil have inevitably been published elsewhere, but there is much new information to be obtained from this book

The bulk of the volume is devoted to a description of the Upper Carboniferous rocks In addition to the descriptive account, ribbon diagrams and other text figures graphically display the variations in the sediments throughout the area They show the thinning of the strata in an easterly direction mainly at the expense of the sandstone members The marine "marker" horizons used for correlation are more persistent, traced in part by fossil evidence and in part by geophysical methods, a point perhaps not too clearly stated in the text The easterly extension of the coalfield is well documented and extracts from the principal bore-holes are given Most of the coal extracted is obtained from only four seams by coal mines winding over one million tons annually A little information is given on the quality of the coal and references are made to analyses

Below the Millstone Grit Series occurs that of the Carboniferous Limestone, which includes, towards the base, rocks of Tournasian (C_1) age The fossil evidence in older rocks is meagre, consisting mainly of horny brachiopods, and no decision on the exact age of these rocks is given, they are referred to Devonian and Lower Palaeozoic Systems

Surface rocks of the Permian and Triassic Systems are described in the sixth chapter The description adds materially to that of the first edition, particularly the petrological data which are entirely new Very little change has been made to geological boundaries and the Ollerton map was re-issued with only minor alterations Permian and Triassic rocks can be distinguished despite lateral and vertical facies changes, and the classic terminology of Permian, Bunter, Keuper and Rhaetic is maintained The Muschelkalk is referred to in a footnote (page 120)

Other surface rocks are briefly mentioned including a half square mile of Liassic rocks (seventh chapter and page 152) and the superficial deposits (ninth chapter)

Geological structures are summarized in the eighth chapter These include not only faults and folds but also the effects of unconformities, particularly that of the Permian rocks on the underlying Coal Measures Sedimentary structures are also described in this section

Detailed accounts of the separate divisions of the sequence are arranged in double columns and small type-face as distinct from the single column spread and larger print of the general accounts This improves the lay-out of the text and enables the general reader to avoid detail In places, however, the column is further reduced in width if details of depth are included and only two or three words occur on a line

The publication of this carefully prepared book on an area containing a number of small oilfields is particularly appropriate at this time when the North Sea bore-hole data are becoming available to increase our knowledge of Carboniferous, Permian and Triassic rocks which occur in that region

F M TAYLOR

STUDENT PHYSICAL CHEMISTRY

Physical Chemistry

By Frank T Gucker and Ralph L Seifert Pp xx+824 (London The English Universities Press, Ltd , 1967) 70s net

THE prospective purchaser of this textbook should take heart from the comment on the dust cover that "mathematics is treated as the good servant, but poor master, it has always proved to be to physical science" With this in mind, the authors introduce their work with a short chapter which is only to be regarded as a swift "refresher" survey of selected mathematical areas

The first section on physical chemistry deals with the nuclides, radioactive decay and nuclear reactions This leads to discussion of nuclear structure and, through the introduction of spectroscopic observations, atomic structure Bonding is discussed in terms of the molecular orbital and valence bond approaches leading to hybrid bonds and the resonance concept

A chapter on molecular properties acquaints the reader with nuclear magnetic resonance, Mossbauer spectra, dielectric and dipole phenomena and molecular spectroscopy. Study of the behaviour of gases introduces the kinetic theory, critical phenomena and equations of state A section on thermodynamics and thermochemistry then leads to a discussion of the properties of solids and liquids coupled with structural considerations

At this point the equilibrium concept is brought in, followed by the third law of thermodynamics and statistical mechanics With this background, solution properties of non-electrolytes and electrolytes are reviewed This involves treatment of acid-base equilibria and the electrochemistry of galvanic cells and electrolyte conductance

A chapter on surface chemistry includes a descriptive approach to the colloid state while that on chemical kinetics had both a classical and transition state approach Among reactions dealt with are molecular, ionic, chain, homogeneous and heterogeneous catalysis

The book concludes with a short chapter on heterogeneous equilibria

This textbook is very easy to read and well set out, with a clear use of tabular matter and diagrams It makes refreshing use of short historical introductions to new ideas and makes a good attempt to render the mathematics digestible. Each chapter is provided with a set of problems and a reading list to take the reader further when appropriate

This is a useful book, very moderately priced and, I believe, with an approach which will commend it to undergraduates J C Robb

DIFFERENTIAL EQUATIONS

Nonlinear Partial Differential Equations

A Symposium on Methods of Solution. Edited by W F Ames. Pp xv+316 (New York Academic Press, Inc , London· Academic Press, Inc (London), Ltd , 1967) 112*s*

The history of non-linear differential equations is nearly as old as that of differential equations themselves, for John Bernoulli studied an equation of Riccati's type as long ago as 1694 Some 200 years elapsed before a really intensive theory developed, to be followed by a remarkable and explosive interest during the past thirty years or so For this, two reasons may be suggested in 1939 problems involving non-linear equations cropped up in the military field, and the advent of high-speed computing machines allowed complex and laborious calculations to be performed with ease Apart from this, investigations such as van der Pol's new method for dealing with Rayleigh's equation had the indirect effect of a slight change in emphasis, mathematicians thought less about seeking for a solution of a non-linear equation and more about what the equation can tell us about a function which satisfies it

Because problems in applied mathematics cannot always be adequately treated by assumptions of linearity and of simple superposition, there is an immense field of application awaiting further progress in the study of non-linear equations Useful texts are available, but perhaps the time is not yet ripe for a comprehensive and classical treatise So the present report of a seminar is of considerable value as an interim survey The reader should, of course, have some knowledge of the basic theory of the non-linear ordinary differential equation, such as can be found, for example, in the excellent introductory book by Davies and James He can then use this volume to bring himself into touch with current research work on the non-linear partial differential equation. For instance, Bellman and Kalaba describe briefly some methods which have recently been tried out, particularly those which are suitable for digital computation, a region to which Bellman has made striking and not always conventional contributions Ames stresses the need of the research worker to escape from the traditional background of linear operators and the principle of superposition, while adapting some of the classical exact techniques of the linear partial differential equation to the non-linear Most of the sixteen papers deal with equations from fluid mechanics, elasticity non-linear wave theory, and other physical topics, and the authors are men actively engaged in research

The editor calls the book a small chapter in a largely unwritten history, but believes that it can be both a source of inspiration and a plea for help Older men cannot easily discard the powerful but restrictive machinery of linearity, young men, free from such inhibitions, have a large domain of theory and application awaiting the properly equipped explorer T A A Broadbent

LIPID CHEMISTRY

An Introduction to the Chemistry and Biochemistry of Fatty Acids and their Glycerides

By F D Gunstone Second edition Pp x+209 (London Chapman and Hall, Ltd , 1967) 63*s* net

In the ten years that have passed since this book was first published, the introduction of new techniques such as thin-layer and gas-liquid chromatography has resulted in a considerable accumulation of accurate analytical and structural data of lipids This trend has simplified rather than complicated the author's task, and in the present volume a concise and logical account of lipid chemistry is possible where previously only empirical classification and description could be applied to much of the subject matter It is appropriate, in view of the author's background, that the chemical and physical properties of lipids should be well described The chapter on fatty acids, their derivatives, isolation, properties and structure is likely to be invaluable to both biologists and chemists seeking a better understanding of the physico-chemical basis of lipid biochemistry These chapters are concise, accurate and readable, and do not confuse the reader with excess detail The inclusion of reference lists permits ready access to the original literature

In a sense, most lipid chemistry is biochemical in that lipids are generally naturally occurring Nevertheless, it is to be expected that biochemistry should contain much over and above the chemistry of natural products, and the title of this book might lead one to hope that the author had effected a multidisciplinary approach to the subject However, only a tenth of the content is concerned with the metabolic interconversions of lipids, and this is a fairly standard account The functional and structural involvement of lipids in biological membranes, surely the major problem of lipid biochemistry, receives two lines of passing mention The same ration is allocated to interactions between lipids and proteins Thus the chemist seeking an introduction to the problems in lipid chemistry set by biological systems is unlikely to be challenged, stimulated or even adequately informed by the "biochemical" content of this book, and may therefore take his much-needed talents elsewhere That would be regrettable, and it is to be hoped that a third edition appearing in another decade would be able to relate the physico-chemical structure of complex lipids to their biological function P B Garland

TWO REPRINTS

The Ninth Bridgwater Treatise

A Fragment. New impression of the second edition By Charles Babbage. (Cass Library of Science Classics, No. 6.) Pp 273 (London Frank Cass and Co, Ltd, 1967. First published 1837) 90*s*

Philosophical Experiments and Observations

By Robert Hooke Edited by W Derham (Cass Library of Science Classics, No 8) Pp 391 (London Frank Cass and Co, Ltd, 1967 First published 1726) 90*s*

THERE is now an almost bewildering variety of facsimile reprints of scientific works of historical interest Inevitably, many duplications occur and the price of these books is high The Cass Library of Science has published several of the less hackneyed works and their price is relatively modest Most commendably they have supplied information often neglected Thus they date their reprints and give brief details of earlier editions, and their general editor, Dr Laurens Laudan, has added an index or analytical table of contents to each volume which makes the books more usable than the original editions He has also added an explanatory note to the Hooke volume The books are sturdy and well reproduced.

Unfortunately these two volumes are not of much importance *Philosophical Experiments and Observations* represents minor Hooke at best, what was left in his papers after Waller had published *The Posthumous Works* Here are miscellaneous notes, jottings and letters, random, disconnected and incomplete, about one-third not by Hooke However, many of these notes illuminate both Hooke's activities and those of his contemporaries

Charles Babbage's *Ninth Bridgwater Treatise* is very much a work of its period, the 1830s, when the "argument from design" was thought worthy of eight separate treatises, paid for by a bequest from the Earl of Bridgwater Babbage, perhaps piqued at not being asked to write an official treatise, wrote this brief and truncated discussion illustrated by probability theory and the calculating machine It is a curious but specialized work, more interesting to historians than scientists

MARIE BOAS HALL

OBITUARIES

Dr A T Waterman

ALAN TOWER WATERMAN, who died at the end of last year, did much for science in the United States During the fifteen years when he served, first as Chief Scientist of the Office of Naval Research and later as Director of the National Science Foundation, he worked constantly in the cause of basic research and education in the sciences.

He was born at Cornwall-on-Hudson, New York, in 1892, and did both his undergraduate and graduate work at Princeton, receiving the degrees of AB in 1913, MA in 1914 and PhD in physics in 1916 His research included investigations of the conduction of electricity through solids, thermionic, photoelectric emission and related effects, and electrical properties of solids After receiving his degree, he became an instructor in physics at the University of Cincinnati During the First World War he spent two years with the Science and Research Division of the Army Signal Corps, where he was engaged in meteorological work At the end of the war he joined the faculty of Yale University and stayed at the department of physics until 1942

From 1941 to 1945 Waterman was associated with the Office of Scientific Research and Development (OSRD), and from 1946 to 1951 was Deputy Chief and Chief Scientist of the newly established Office of Naval Research (ONR), Department of the Navy He was one of the principal architects of the policies and programmes of ONR in supporting scientific research He interpreted broadly the types of research which were important to the navy, and provided a means of supporting fundamental research that might otherwise not have been supported at a time when the Federal Government's resources were concentrated on applied science, chiefly concerned with defence and atomic energy Under Waterman the ONR sought advice from scientific organizations, and when necessary established advisory committees outside the navy

The Office of Naval Research became a model for government support of basic research, and pointed out the need for a national foundation to support this kind of research, but on an even broader basis.

On April 6, 1951, President Truman appointed Waterman the first director of the newly formed National Science Foundation, for a six year term In 1957 President Eisenhower reappointed him to this post, and although he reached the compulsory retirement age before the end of his second term Waterman continued in his post until June 1963, at the special request of President Kennedy

While he was in charge of the National Science Foundation, Waterman not only stressed the importance of supporting, through the universities, pure research which was not of immediate significance, but he also encouraged the social sciences, and there was a steady growth in support for these subjects

He always stressed the importance of education and training for scientists, and through a gradually expanding programme of fellowships the Foundation has sought to make graduate training available to all the best students In 1953 the first projects began with summer institutes for teachers of high school and college mathematics and science, and curricula for schools and colleges have since been revised While at the National Science Foundation, Waterman was able to inform the public of the importance of education and research From Congress he obtained an initial grant of 3 5 million dollars which had increased to 40 million dollars by 1957

After retiring, Waterman maintained an active interest in science and education by serving on numerous boards and committees including the Board of Trustees of Atoms for Peace Awards, the Advisory Board of Georgetown University Center for Strategic Studies and the Liaison Committee on Science and Technology of the US Library of Congress He was special consultant to the President of the National Academy of Science and chairman of the Committee on Scholarly Communication with Mainland China, consultant to the Administrator of the National Aeronautics and Space Agency and a member of its Historical Advisory Committee

Waterman was a fellow of the American Association for the Advancement of Science, and served as president in 1963 and chairman of the board in 1964 He also belonged to the American Physical Society and the New York Academy of Sciences He was a member of the American Association of University Professors, the American Institute of Electrical Engineers, the American Rocket Society, the American Polar Society, the Washington Academy of Sciences, the Washington Academy of Medicine, Phi Beta Kappa, Sigma Xi, the Scientific Research Society of America, and the Washington Philosophical Society In October 1967, the American Institute of Physics awarded him the Karl Taylor Compton gold medal for distinguished statesmanship in science

Waterman was an accomplished musician—he mastered the Scottish bagpipes and for many years played the violin, cello and viola in a string quartet, first established during his undergraduate days at Princeton University and later composed of his Washington scientific colleagues He also frequently entertained his associates on the piano and guitar Another great interest was his love of the woods. He was a licensed guide in the State of Maine, and he continued this activity whenever his official duties permitted a rare canoe or camping trip

University News

Edinburgh

Dr D S Falconer, at present deputy director of the ARC Unit of Animal Genetics, has been appointed to a personal chair in genetics Dr Falconer will take up his appointment on April 1 when he will also become director of the ARC unit in succession to Professor C H Waddington

University College of Swansea

Professor E T Nevin, professor of economics at the University College of Wales, Aberystwyth, has been appointed professor of economics and head of the Department of Economics

Announcements

The Paul Ehrlich and Ludwig Darmstaedter prizes have been jointly awarded to Professor W Morgan, director of the Lister Institute of Preventive Medicine, and Professor O Westphal of Freiburg The prizes were awarded for contributions in the fields of physiology and medicine

Erratum In the article "Not Enough Uranium" (*Nature*, 217, 893, 1968) the estimates of available resources of uranium at a price of less than $10 a lb of U_3O_8 should have read 700,000 short tons, with a further 126,000 short tons available as by-products, not 7,000 short tons

Erratum In the report of the symposium of the Experimental Plant Taxonomy Group of the Linnean Society (*Nature*, 217, 902, 1968), *Potentilla anglica* was quoted wrongly as an alltetraploid which forms trivalents at meiosis, it is, in fact, an allo-octaploid which forms only bivalents at meiosis

Erratum In the article "Haemoglobin Torino—α43 (CD1) Phenylalanine→Valine" by A Beretta, V Prato, E Gallo and H Lehmann (*Nature*, 217, 1016, 1968), in lines 22 and 27 of column two, page 1018, the words higher and lower are interchanged The amount of haemoglobin A is higher in heterozygotes for haemoglobin A and α-chain abnormal haemoglobins, and lower with β-chain abnormal variants

CORRESPONDENCE

The Reference Problem

Sir,—One of the most irritating features of the work of editing, typing and publishing a scientific paper must surely be the problem arising in connexion with the bibliography, or citation of references to other literature Yet that problem ought to be readily soluble

The advantages of standardization in literature references will be obvious to author, typist and editor alike in the interests of the author, such standardization would allow the choice of journal to be made with convenience after the manuscript has been edited, for the typist it would mean easy, rapid copying from standard filing cards, while the editor would be spared the boring task of altering punctuation, the ordering of initials, and so on Both the American Standard Association (ASA) and the British Standards Institution (BSI) have prepared style manuals with sections devoted to bibliography It is conceivable that the assessments and recommendations of the ASA and the BSI are occasionally inapplicable for certain reasons Indeed, it is admissible that the forms of documentation needed in different fields are so multifarious that universal standardization is probably unattainable In going from the general to the particular, however, it does seem likely that the difficulties involved would diminish, so that it ought to be feasible to achieve bibliographic standardization among, for example, those journals devoted to biology In 1960, the Committee on Form and Style of the Conference of Biological Editors prepared a *Manual for Biological Journals* dealing with style in writing, and a second edition of this work was published in 1964 Unfortunately, the resolutions passed by this committee have not been acted on generally, this is clearly evident from a perusal of the late issues of just a small sample of biological journals, namely, those containing papers on genetics

To underline the point, here follow some references as they appeared in recent numbers of different journals on genetics

Mirsky, A E , and H Ris, 1951 The desoxyribonucleic acid content of animal cells and its evolutionary significance J Gen Physiol **34** 451–462 (Genetica, **57**, 13, 1967)

Lerner, I M , and F K Ho 1961 Genotype and competitive ability in Tribolium species Amer Natur 95 329–343 (Amer Natur , **101**, 274, 1967)

Inasmuch as bibliographic standardization on a broad basis is probably unrealizable, and because in practice geneticists, for example, will only rarely come into professional contact with journals devoted to economics or theology, it may be worthwhile for the geneticists themselves to try to introduce some uniformity into the reporting of work in their own field

The next Congress of Genetics, to be held in Tokyo in the summer of 1968, will certainly convene the vast majority of editors of journals on genetics At that time a meeting could easily be arranged at which all these editors could debate the problem mooted here Other difficulties might be aired and perhaps solved at the same time The matter of illustrations deserves some consideration some journals ask for original drawings with complete lettering, others for drawings without lettering, still others for photographs or photocopies of the drawings, and so on The lay-out of the summary or abstract, of the acknowledgments and of the footnotes could also be discussed

In the event of some agreement being reached, either the officers of the congress, the members of the Permanent Committee for Genetic Congresses, or the members of some other committee yet to be appointed, could easily communicate the suggestions resulting from the editors' deliberation to the International Union of Biological Sciences (IUBS) In its turn, the IUBS could pass on these suggestions to other members of the union and, eventually, to the main body of the scientific community

Yours faithfully,

Frederic A Lints

FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Monday, March 25

Institution of Electrical Engineers (joint meeting with the Automatic Control Group of the I Mech E , at Savoy Place, London, WC2), at 5 30 p m —Discussion Meeting on "Fluidics and Integrated Circuits" opened by Dr R C Foss and Dr K Foster

Institution of Mechanical Engineers, Automobile Division (at 1 Birdcage Walk, Westminster, London, SW1), at 6 p m —Discussion Meeting on "The Impact of Proposed Vehicle Noise Regulations"

Royal Society of Arts (at John Adam Street, Adelphi, London, WC2), at 6 p m —Dr C H G Oldham "China To-day—Science" (second of three Cantor Lectures)

Tuesday, March 26

Institution of Civil Engineers (at Great George Street, London, SW1), at 5 30 p m —Mr J E Prosser and Mr P A St C Grant "The Tyne Tunnel —Planning of the Scheme", Mr R H Falkiner and Mr S G Tough "The Tyne Tunnel—Construction of the Main Tunnel"

Institution of Mechanical Engineers, Railway Engineering Group (at 1 Birdcage Walk, Westminster, London, SW1), at 6 p m —Discussion Meeting on "High Density Vehicles"

Society of Chemical Industry, Plastics and Polymer Group (at 14 Belgrave Square, London, SW1), at 6 p m —Dr W I Bengough "Thermal Degradation of PVC in Solution"

Tuesday, March 26—Thursday, March 28

Systematics Association (at the University of Nottingham School of Agriculture, Sutton Bonington)—Symposium on "The Soil Ecosystem (Systematic Aspects of the Environment, Organisms and Communities)"

Wednesday, March 27

Institution of Electrical Engineers (at Savoy Place, London, WC2) at 5 30 p m —Mr G S Buckingham "Elegant Heating—by Electricity" (Sixth Annual Lecture of the Power Division)

Institution of Electrical Engineers (at Savoy Place, London, WC2), at 5 30 p m —Professor G Kino "Waves in Semiconductors—Possibilities for New Solid State Devices"

Society of Environmental Engineers (in the Mechanical Engineering Department, Imperial College, London, SW7), at 5 30 p m —Annual General Meeting

Institution of Mechanical Engineers (at 1 Birdcage Walk, Westminster, London, SW1), at 6 p m —Mr D T N Williamson "The Pattern of Batch Manufacture and Its Influence on Machine Tool Design" (James Clayton Lecture)

Royal Society of Arts (at John Adam Street, Adelphi, London, WC2), at 6 p m —Sir Paul Chambers, KBE "Technological Progress in Industry" (Trueman Wood Lecture)

Society of Chemical Industry, Food Group—Nutrition Panel (at 14 Belgrave Square, London, SW1), at 6 15 p m —Annual General Meeting, followed by Dr T H Grenby ' Some Aspects of Food and Dental Caries"

Wednesday, March 27—Thursday, March 28

Institution of the Rubber Industry, London Section (at the Kensington Close Hotel, London, W8)—Conference on "Modern Polymers—New Developments and Applications"

Royal Society (at 6 Carlton House Terrace, London, SW1), at 10 30 daily—Discussion Meeting on "Results of the Royal Society Expedition to the British Solomon Islands Protectorate, 1965" organized by Professor E J H Corner, FRS

Wednesday, March 27—Friday, March 29

Royal Microscopical Society (at Imperial College, London, SW7)—European Symposium on "Cytochemistry in Electron Microscopy"

Thursday, March 28

University of Liverpool (in the University Lecture Room Building) at 9 30 a m —Symposium on "Mathematical Models in Oceanography and Meteorology"

Gas Chromatography Discussion Group, Liquid Chromatography Sub-Group (at the Institute of Petroleum, 61 New Cavendish Street, London, W1), at 3 p m —Scientific Papers

Institution of Civil Engineers, Hydrological Group (at Great George Street, London, SW1), at 5 30 p m —Informal Discussion on "Investigations Following a Catastrophic Flood" introduced by Mr C Clay

Institution of Electrical Engineers (at Savoy Place, London, WC2), at 5 30 p m —Professor W H G Armytage "The Engineer in Society"

Institution of Electronic and Radio Engineers, Aerospace, Maritime and Military Systems Group (at 8–9 Bedford Square, London, WC1), at 6 p m —Mr T H Kerr "Cost Effectiveness and Systems Analysis in Defence"

Thursday, March 28—Friday, March 29

Association of Clinical Biochemists (at Newcastle upon Tyne)—Eighth West-European Symposium on Clinical Chemistry—"Immunology in Clinical Chemistry" (Organized in collaboration with the Societies of Clinical Chemistry of Belgium, France, Holland, Switzerland and West Germany)

Institution of Mechanical Engineers, Automobile Division (at 1 Birdcage Walk, Westminster, London, SW1)—Symposium on "Corrosion and Its Prevention in Motor Vehicles"

Mineralogical Society, Clay Minerals Group (in the Geology Department, The University, Southampton)—Meeting on "Clay Mineralogy of Sediments"

Society of Chemical Industry, Fine Chemicals Group and the Birmingham and Midland Section, in association with the University of Birmingham (at the University of Birmingham)—Symposium on "Fluoro-Organic Compounds"

Friday, March 29

Gas Chromatography Discussion Group (at the Royal Institution, Albemarle Street, London, W1)—Informal Symposium on "Gas Chromatography"

Institution of Electrical Engineers (joint meeting with the Automatic Control Group of the I Mech E , at Savoy Place, London, WC2), at 2 p m —Colloquium on "Building Models with Plant Data"

British Mycological Society (at the School of Pharmacy, 29–39, Brunswick Square, London, WC1), at 10 45 a m —Special General Meeting, 11 a m —General Papers

Monday, April 1

Institution of Electrical Engineers (at Savoy Place, London, WC2)—Colloquium on "Injection Luminescence"

Institution of Mechanical Engineers, Medical Engineering Working Party (at 1 Birdcage Walk, Westminster, London, SW1), at 6 p m —Discussion Meeting on "Kidney Machines—Technical, Medical and Social Problems"

Royal Society of Arts (at John Adam Street, Adelphi, London, WC2), at 6 p m —"Industry and Commerce" (Last of three Cantor Lectures on "Modern China")

Society of Engineers (at the Geological Society, Burlington House, Piccadilly, London, W1), at 6 p m —Dr R Davies "High Speed Forming of Metals"

Society of Chemical Industry, London Section (at 14 Belgrave Square, London, SW1), at 6 30 p m —Dr N W Pirie, FRS "The Use of Novel Proteins in Human Food"

Monday, April 1—Wednesday, April 3

British Biophysical Society (at the University of Nottingham)—Meeting on "Biological Semiconductors"

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Lecturer (preferably with special interests in geomorphology and meteorology) in Geography—The Director of Academic Studies, Trinity and All Saints' Colleges, Brownberrie Lane, Horsforth, near Leeds (March 27)

Senior Lecturer or Lecturer, Grade II (qualified to lecture to honours degree standard and with active research interests) in Geography—The Secretary, Sir John Cass College, Jewry Street, London, EC3 (March 28)

Senior Lecturer in Statistics—The Registrar, University College of Wales, Aberystwyth (March 30)

Senior Lecturer (Clinical) in the Department of Pathology, University of Birmingham—The Assistant Registrar, Medical School, Birmingham 15 (March 31)

Lecturer in Botany in the Department of Arts, Science and Education—The Registrar, University of London Goldsmith's College, New Cross, London, SE14 (April 1)

Lecturer or Assistant Lecturer (preferably with an interest in teaching sociology to students of applied science) in Sociology—The Registrar and Secretary, The University, Leeds, quoting Ref No 68/19/3 (April 1)

Temporary Assistant Lecturer or Temporary Lecturer (with a good honours degree in physics and successful school teaching experience) in the Department of Education—The Registrar and Secretary, The University, Leeds, quoting Ref No 68/15/3 (April 1)

Lecturer in Applied Sociology—The Secretary of the University Court, The University, Glasgow (April 3)

Lecturer (preferably with an interest in, and experience of, some branch of experimental botany other than physiology or biochemistry) in Botany—The Registrar (Room 39, O R B), The University, Reading (April 6)

Chair of Electrical Engineering, and Chair of Mechanical Engineering at the University of Malaya—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (Malaya and London, April 8)

Lecturer (experienced graduate teacher of biology and competent to contribute to both the practical and academic work of the University Education Department) in Education—The Secretary, University of Durham, Old Shire Hall, Durham (April 10)

Lecturer (preferably candidate in numerical analysis) in Pure Mathematics—The Secretary, The University, Aberdeen (April 13)

Research Assistant (with a university degree in chemistry or biochemistry or an equivalent qualification) in Biological Chemistry, for work concerned with the biogenesis of membranes, under the direction of Dr Sargent—The Secretary, The University, Aberdeen (April 13)

Lecturer in Physics at the University of Cape Town—The Secretary-General, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1, and The Registrar, University of Cape Town, Private Bag, Rondebosch, Cape Town, South Africa (April 15)

Lecturer (science graduate) in Biochemistry at the University of Otago, Dunedin, New Zealand—The Secretary-General, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (New Zealand and London, April 15)

Chair of Electronic Engineering—The Registrar and Secretary, The University, Leeds, quoting Ref No 68/33/1 (April 17)

Research Assistant (with a good honours degree or M Sc in microbiology, bacteriology, botany or other appropriate subject) in Soil Microbiology in the Hartley Botanical Laboratories—The Registrar, The University, Liverpool, quoting Ref RV/397/N (April 22)

Chair of Agronomy at the University of Sydney, Australia—The Secretary-General, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (Australia and London, April 30)

Scientific Information Officer (with a degree in agriculture, ability to write good English and a flair for languages)—The Director, Commonwealth Bureau of Pastures and Field Crops, Hurley, near Maidenhead, Berkshire (May 15)

NOW! REFRIGERATED

The ULTRORAC is an even better answer

The LKB 7000 ULTRORAC now the most advanced, reliable, practical, complete fraction collector on the market today.

Compact, yet takes 200 tubes—Modern, yet backed by years of experience, Low Priced, yet highest in performance. Drop, time or volume collection. Will operate as well at —5°C as at normal temperatures. The new "flow-stop" prevents loss of samples, allows collection of acids, radio active substances and corrosives in perfect safety (by positively preventing drops falling between tubes), protects the UltroRac in case of power failure and shuts down collection after pre-determined number of tubes are served.

LKB design—LKB precision—LKB know-how has resulted in LKB making and marketing more fraction collectors than any other Company in the World—why not prove LKB reliability by writing TODAY for full particulars of the LKB 7000 UltroRac Fraction Collector with the LKB 7017A UltroRac Valve.

APPOINTMENTS VACANT

UNIVERSITY OF OXFORD

LECTURER IN ZOOLOGY AND CURATOR OF THE ZOOLOGICAL COLLECTIONS

The University proposes to appoint a Lecturer in Zoology and Curator of the Zoological Collections (which do not include insects). The salary will be according to age on the scale £1,470 to £2,900 (with F.S.S.U.).

Applications (six copies, except in the case of overseas applicants who need only submit one copy), including a statement of age, qualifications and experience, and giving the names of two referees, should be sent to the Secretary of Faculties, University Registry, Broad Street, Oxford, not later than April 27, 1968. The Lecturer and Curator will be expected to take up office as soon as possible after October 1, 1968.

The Lecturer will be responsible to the Linacre Professor for the care of the Zoological Collections in the University Museum and in the Department of Zoology. He will be required to arrange the supply of material and the preparation of displays and other aids for teaching and research, to cooperate in the teaching and administrative work of the Department of Zoology in both term and vacation under the direction of the Linacre Professor, and to engage in advanced study and research. (X1184)

UNIVERSITY OF IFE

NIGERIA

Applications are invited for

(i) Two Senior Lectureships and two Lectureships in CHEMISTRY. For the Senior Lectureships candidates should have special interests in Physical Chemistry or in Organic Chemistry and National Products. For the Lectureships preference will be given to candidates with special interests in Physical and Inorganic Chemistry.

(ii) Professorship and Senior Lectureship in ZOOLOGY. Candidates with interests in any fields (except parasitology) considered; an interest in vertebrate biology particularly welcomed.

Salary: Professor £N3,000 p.a., Senior Lecturer £N2.275 to £N2,575 p.a., Lecturer £N1,200 to £N2,175 p.a. (£N1 = £1 3s. 4d. sterling). Salary supplementation in range £240 to £600 p.a. (sterling) in appropriate cases under British Expatriate Supplementation Scheme. Superannuation; family passages; various allowances; annual U.K. leave where applicable.

Detailed applications (six copies), naming three referees, by April 23, 1968, to Inter-University Council, 33 Bedford Place, London, W.C.1, from whom particulars are available. (1137)

HOUGHTON POULTRY RESEARCH STATION

(Financed jointly by the Agricultural Research Council and the Animal Health Trust)

PHYSIOLOGY AND BIOCHEMISTRY DEPARTMENT

ENGINEER required to assist with the development of controlled environment systems for experimental work with poultry and to supervise the ventilating and heating plant in a new isolation unit. Candidates should have H.N.C. in mechanical or electrical engineering, or an equivalent qualification, and training in technical drawing and workshop practice. Experience of air-conditioning systems in buildings, ships, or aircraft would be an advantage. Appointment in the Experimental Officer grade (£1,365 to £1,734 per annum) according to age, qualifications, and experience.

Further particulars and application forms from the Secretary, Houghton Poultry Research Station, Houghton, Huntingdon, to whom completed application forms should be returned by March 31, 1968. (1172)

CSIRO
AUSTRALIA

RESEARCH SCIENTIST

ARCHITECTURAL ACOUSTICS

DIVISION OF BUILDING RESEARCH

GENERAL The Division of Building Research of the Commonwealth Scientific and Industrial Research Organization, located at Highett, Victoria, is primarily responsible for long-term research on building and associated engineering. Particular attention is given to studies of building materials and design, thermal environment, tropical building, operational research and architectural acoustics.

DUTIES The appointee will be required to take part in the Division's study of architectural acoustical problems and to initiate such studies especially in noise control and room acoustics both in the field and in the laboratory and to give advice to industry.

QUALIFICATIONS Applicants should have a Ph.D. degree in Physics, Engineering or Mathematics, or postgraduate research experience of equivalent standard and duration, supported by satisfactory evidence of research ability.

SALARY Depending upon qualifications and experience, the appointment will be made within the salary range of Senior Research Scientist, $A,6892–$A7,974 p.a., or Principal Research Scientist, $A8,242–$A9,490 p.a. Salary rates for women are $A428 p.a. less than the corresponding rates for men. Promotion within CSIRO to a higher classification is determined by merit.

CONDITIONS The appointment, which carries with it Commonwealth Superannuation Fund or Provident Account privileges, will be conditional upon passing a medical examination. An initial probationary period of twelve months may be specified. Fares paid for the appointee and his dependent family. Further particulars supplied on application.

Applications (quoting Appointment No. 390/388) stating full name, place, date and year of birth, nationality, marital status, present employment, details of qualifications and experience, together with the names of not more than four persons acquainted with the applicant's academic and professional standing, should reach:

Mr. R. F. Turnbull, Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, by the **19th April, 1968.** (1162)

Headquarters Allied Forces Central Europe

BRUNSSUM **THE NETHERLANDS**

Vacancy for a

Chief of Operations Research Unit

1. Applications are invited for the post of Chief of Operations Research Unit (NATO-A-7), which will be vacant from 1st July, 1968, at the Headquarters Allied Forces Central Europe, Brunssum, the Netherlands.

2. The duties required will be:

a. to initiate and direct scientific studies of weapons, tactics, equipment and strategy designed to furnish a quantitative basis for command of decisions.

b. to provide the Command with ready and informal access to scientists with specialized training in the techniques applicable to the analysis of modern warfare.

c. to maintain a close liaison with other national and international Operations Research and Analysis organizations.

d. to act as Scientific Adviser to the Commander, AFCE and to keep him and his staff informed of scientific and technical developments related to the mission of the Command.

3. Candidates for this post must have a university degree of good standing in science, preferably in physics, mathematics or a related subject. Candidates must have had some years experience of Operations Research, preferably in the field of air warfare and should have achieved some official standing of reputation in their own countries in this work. Familiarity with the problems of strategic offence, air defence, tactical support and especially with guided weapons and electronics as applied to these fields would be added qualifications. Fluency in one of the NATO official languages is essential; a working knowledge of the other is desirable.

(1171)

AGRICULTURE

General Agriculturists and agricultural specialists of many kinds are frequently required in the effort to match the large demand from the developing countries The vacancies advertised below are a selection from the many openings which exist now While they are being filled, other vacancies are arising

Salaries within the ranges quoted are assessed on qualifications and experience, and the terms of most appointments include free or subsidized accommodation, education grants, family passages, good leave on full pay, etc A contributory pension scheme is available in certain circumstances

Most appointments are limited to nationals of the United Kingdom or the Republic of Ireland who are normally resident in those countries

BOLIVIA

Pasture Research Officer (British Tropical Agricultural Mission). RC 213/22/03

Duties To continue a programme of research on intensive grasses in crop rotations and to advise and work in collaboration with Bolivian technicians on experiments, extensions, seed multiplications, field surveys, etc , with natural and cultivated pastures

Qualifications and Terms An honours degree in botany with post graduate experience of range management in the tropics and of work on intensive grasses A working knowledge of Spanish is desirable Salary £2,500–£3,100 a year, depending on qualifications and experience, subject to British Income Tax, plus a variable non-taxable overseas allowance currently payable at rates from £540–£1,310 a year depending on marital status Contract 2 tours of 18 months

Head of British Mission for Tropical Agriculture RC 213/22/01

Duties To lead team of Agricultural experts in current important programme and to be Adviser to Bolivian Government in Tropical Agriculture

Qualifications and Terms A relevant degree and wide experience of agricultural administration in Tropics at least at Deputy Director level Salary £4,500–£5,000 a year subject to British Income Tax plus a variable non-taxable overseas allowance currently payable at rates from £540–£1,310 a year depending on marital status plus entertainment allowance of £250 a year. Contract 2 tours of 18 months

MALAWI

Senior Agricultural Officer (Irrigation) RC 213/134/015

Duties To work as part of an irrigation team

Qualifications and Terms A degree in agriculture with at least ten years experience, preferably under tropical conditions Salary £2,655 a year plus 15%–25% terminal gratuity A supplement of £100 is also payable direct to an Officer's bank account outside Malawi and Rhodesia Contract 2–3 years

FALKLAND ISLANDS

Grasslands Officer RC 213/60/01

Duties To investigate and experiment on development and improvement of grasslands and possibly to establish a small experimental station

Qualifications and Terms A degree in agriculture with experience in hill grazing improvement Salary £1,500–£2,000 a year 15% terminal gratuity Contract 30–36 months

FIJI

Soil Conservation Officer RC 213/62/07

Duties Supervision and maintenance of technical standards in soil conservation work, by liaison with District Agricultural Officers who administer all soil conservation extension, machinery and field staff Arrange in-service training in soil conservation for field staff Prepare lectures and examinations for the soil conservation course at the Fiji School of Agriculture Assist in preparation of soil conservation publicity Advise on soil conservation matters through the Director of Agriculture or through the Land Conservation Board

Qualifications and Terms A degree in Agriculture or Science with experience in practical soil conservation Experience in tropical agriculture is desirable Salary £ Fijian 1,092–2,181 a year (£ Sterling 1,045–2,087 a year) An inducement allowance at present in the range of £ Sterling 508–829 a year is also payable Terminal gratuity 25% of basic salary and inducement allowance Contract 1 tour of 30–36 months

Soils Scientist RC 213/62/09

Duties To carry out soil surveys on a detailed regional basis to follow on the reconnaissance survey already completed and to be responsible for field soil survey work on proposed development areas

Qualifications and Terms A 1st or 2nd class Honours degree in Geology or Geography and postgraduate experience in soil surveys in tropical areas Salary £ Fijian 1,092–2,181 a year (£ Sterling 1,045–2,087 a year) An inducement allowance at present in the range of £ Sterling 508–829 a year is also payable Terminal gratuity 25% of basic salary and inducement allowance Contract 1 tour of 30–36 months

SABAH

Agricultural Research Officers (Plant Breeders) RC 213/150/03

Duties To deal with the selection and breeding of oil palm and cocoa throughout the State of Sabah

Qualifications and Terms An Honours degree in Natural Science with 2 years post-graduate training A good general knowledge of the subject is essential Field experience desirable Salary $9,000–17,040 a year (£ Sterling 1,226–2,321 a year) plus an inducement allowance at present in the range of £ Sterling 804–1,303 a year Terminal gratuity approximately 20% of basic salary and inducement allowance Contract 2–3 years

Agronomist RC 213/150/04

Duties To manage a cocoa or oil palm research station, to investigate cultivation and fertilizer applications and to implement the departmental research programme

Qualifications and Terms A degree in natural science with two years postgraduate training Salary $9,000–17,040 a year (£ Sterling 1,226–2,321 a year) plus an inducement allowance at present in the range of £ Sterling 804–1,303 a year Terminal gratuity approximately 20% of basic salary and inducement allowance Contract 2–3 years

TANZANIA

Agricultural Economist RC 213/267/011

Duties To lead the Planning and Investigation Unit of the Ministry of Land Settlement and Water Development in the examination and valuation of settlement and irrigation schemes and to train officers engaged on these schemes

Qualifications and Terms A degree in economics with agricultural qualifications or an honours degree in agricultural economics plus some previous experience Basic salary scale E A Shs 33,200–36,000 a year (£ Sterling 1,936–2,100) liable to Tanzanian income tax In addition an inducement allowance, normally tax free, at present in the range of £ Sterling 1,113–1,140 a year will be paid by the British Government direct to an officer's bank account outside East Africa Terminal gratuity 25% of basic salary and inducement allowance Contract 21–27 months

ST. HELENA

Agricultural and Forestry Officer RC 213/151/01

Duties To take charge of the Department which is responsible for forests, grazing and arable land

Qualifications and Terms A degree or diploma in agriculture preferably with overseas experience Salary £1,529–£2,117 a year 12½% terminal gratuity Contract 2 years

For further particulars of these vacancies and an application form please write giving your full name, age and brief details of professional qualifications and experience, and quoting appropriate reference number, to the Appointments Officer, Room 324/N/15, Ministry of Overseas Development, Eland House, Stag Place, London, S W 1.

MINISTRY OF OVERSEAS DEVELOPMENT

(1151)

1966 English China Clays group

SCIENTISTS

The Research Department of English Clays Lovering Pochin & Co. Ltd., the major operating Company of the English China Clays Group and the world's largest producer of China Clay, has a number of vacancies for Scientists and Assistants between 18 and 30 years of age.

CHEMICAL ENGINEERING

Two young graduates are required in the Chemical Engineering Section, in which a wide range of work is undertaken Particular emphasis is laid on research into the processing of fine particles Previous experience is not essential for either of these posts and the discipline of the degree is less important than a genuine enthusiasm for research

PHYSICISTS

Two graduate physicists are required, one for work on particle size measurement of fine powders to study the principles involved and various semi-automatic measuring methods The other would work in the field of mineral studies using electro and X-Ray diffraction and various associated techniques

CHEMISTRY

A graduate Chemist is required, who is prepared to develop an interest in Polymers, their Synthesis and Absorption on solid surfaces Applications are invited from men with a Research background in Organic or Physico-Organic Chemistry

SCIENTIFIC ASSISTANTS

There are also a number of vacancies for assistants in the Research Department These posts cover a wide range of disciplines including Chemistry (both Research and Analytical), Physics and Chemical Engineering

The minimum qualifications required for these positions is likely to be Ordinary National Certificate or equivalent For one of the posts, experience in the Building Industry, with particular reference to concrete aggregates, would be useful

---

The well established and expanding Research Department is concerned with all aspects of Research into the nature of China Clay and the Company's production processes China Clay production now exceeds two million tons per annum and over 75% of this is exported The principal industries served are Paper and Ceramics, but China Clay is also used in a wide variety of other manufacturing Industries The Research Department is housed in new Laboratories at St Austell, near the South Cornish Coast

Salaries for the above appointments will be commensurate with age, qualifications and experience

Pension and Life Assurance Schemes operate through the Group, together with a Profit Participation and Long Service Award Scheme Assistance is given towards furniture removal expenses

Please apply in writing, giving brief details of age, qualifications, experience and present salary to

The Company Secretary,

ENGLISH CLAYS LOVERING POCHIN & CO. LTD.,

John Keay House, St Austell, Cornwall

(1196)

NEW ZEALAND

Marine Department

Applications are invited for the undermentioned vacancies

Vacancy B 13/13/17/757

THREE SCIENTIFIC OFFICERS

The Fisheries Research Division of the Marine Department requires three Scientific Officers, two for research on Mollusca and Demersal Fish and one Biometrician for work in population dynamics

Qualifications desired Applicants should have a degree with 1 or 2A Honours in Zoology or Mathematics in the case of the Biometrician

Salary Appointments will be made in the range NZ$2 790 for first-class Honours NZ$2 900/NZ$3 350 for a newly qualified Ph D, and up to NZ$5 670 for suitably experienced scientists

Passages Fares for appointee and his wife and family, if married will be paid

Incidental expenses Up to £35 for a single man and £100 for a married man can be claimed to cover the cost of taking personal effects to New Zealand

Application forms and general information are available from the High Commissioner for New Zealand, New Zealand House, Haymarket, London, S W 1, with whom applications will close on April 22, 1968

Please quote reference B 13/13/17/757 when inquiring (1136)

NEW ZEALAND

Marine Department

Applications are invited for the undermentioned vacancy

Vacancy B 13/13/19/759

SCIENTIST

The Research Division of the New Zealand Marine Department requires a Scientist for their Wellington Research Laboratory, the appointee to take up duty as soon as possible Work is on freshwater fisheries and allied limnological problems, and the qualifications desired are an Honours degree or Ph D

Appointments will be made in the salary range NZ$2,790 for first-class Honours and up to NZ$3,350 for a newly qualified Ph D

Passages Fares for appointee and his wife and family, if married, will be paid

Incidental expenses Up to £35 for a single man and £100 for a married man can be claimed to cover the cost of taking personal effects to New Zealand

Application forms and general information are available from the High Commissioner for New Zealand, New Zealand House, Haymarket, London, S W 1, with whom applications will close on April 24, 1968

Please quote reference B 13/13/19/759 when inquiring (1135)

UNIVERSITY COLLEGE OF WALES

ABERYSTWYTH

DEPARTMENT OF ZOOLOGY

Applications are invited for the post of a RESEARCH ASSOCIATE ELECTRON-MICROSCOPIST to join a Cell Research Group engaged in investigating the nature of the adhesive mechanism at the cell surface The research group is at present supported by the Science Research Council but it is due to be taken over by the College The salary is in the post-doctoral range equivalent to an Assistant Lectureship (£1,105 to £1,340) with F S S U provision

Applications, with the names of two referees and enquiries for further information should be sent to Professor B M Jones, Department of Zoology, University College of Wales, Aberystwyth (1193)

NATURE Volume 217
MARCH 30, 1968

Scandal in the Schools

THE compromise which has been reached between the Schools Council and the Standing Conference on University Entrance (see page 1199) is about the only device by means of which an agreement on the sixth-form curriculum in Britain can be reached within the next few years, which is something in its favour With any luck, the working party which is to be set up jointly between the two organizations may even be more successful and decisive than the sheaf of committees which occupy the time of the Schools Council and its servants The result could well be that all concerned will be persuaded that the time has finally come for radical change—and that the schools representatives will somehow be persuaded that the universities are at least half serious when they declare their belief in a broader—not a narrower—pattern of studies in the sixth form The danger, of course, is that the new committee will be used not as a launching pad for a new pattern of teenage education but as a device for muffling honest disagreement and for stifling honest discontent That is why it is important to remember that, even though the formation of the new working group may seem to some to be a remarkable development, it is in the last analysis merely a compromise between reason and obscuranticism It is not in itself a reform but a kind of bran tub from which, with good fortune, reform may yet be snatched.

In the circumstances, a little recrimination is not entirely out of place The conflict which came to a head and a temporary resolution last week has been building up for several years To be fair, the formation of the Schools Council four years ago has helped to strengthen concern among all kinds of educationists for the balance between the schools and the universities In the schools, perceptive teachers were made painfully aware of two quite separate kinds of problems For one thing, some academics among the teachers were conscious of how the increasing difficulty of maintaining what are called academic standards in the face of the increasing pressure of the examination syllabuses and the competition to enter the universities Others, however, were more conscious of the rapidly growing population of the traditional sixth-forms, and of the growing diversity of the interests and capabilities of their older students

To meet these quite separate considerations, the Schools Council has helped the schools to hammer out in quick succession two quite unsuitable and even unacceptable compromises First, two years ago, there was a scheme for a mixed bag of sixth-form courses, with some full-length courses as at present and some half-length courses to permit some degree of broadening in the curriculum To the extent that this device would have allowed the two groups of interested parties in the schools to go their separate ways, some progress seemed to have been made The trouble, of course, was that even if the scheme had been workable—and nobody ever really spelled out whether a half-course was to be regarded as a partial substitute for or a complement to a full course—the educational equivalent of Gresham's law would have ensured that sixth form students would enjoy the worst of both worlds. This is why it is still something of a puzzle that the Schools Council was brash enough to substitute for this scheme, in its proposals published in the autumn last year, a curious suggestion that the pressure of competition for university places would somehow be diminished if most students bent on going on to higher education were to be examined in only two subjects, and not in three as is at present usually the case This is the proposal which the universities seem now gently but firmly to have rejected and it is disingenuous of the Schools Council to suggest that the whole fiasco has served the useful purpose of persuading lions and lambs to lie down together The truth is that the council has seriously damaged its credibility, as the saying goes Nobody can now take very seriously a body which can so seriously misjudge not merely the temper of the universities with which it must negotiate, but even the interests of education with which it is supposed chiefly to be concerned

If therefore the formation of the working party is a hopeful sign, there is also a danger that its work will be hampered by the pettifoggery which has marked the doings of the Schools Council in the past few years In particular, there is a danger that the working party will somehow be so impressed with the solemnity of the task on which it is embarked that it will perpetuate the spirit of compromise in which it has begun, whenever possible, substituting experiment for decision Yet the problems of the transition from secondary to higher education, though formidable, are simple enough, and enough is known about them for the general framework for workable solutions to be established quickly

Quite simply, British schools should be so organized that it is not necessary for potential academics to declare themselves at a tender age In particular, there should be no reason why a student at school should be compelled to decide several years in advance which kinds of courses he will follow at his university Briefly, schools should aim to provide a general education, but this is not the same thing as saying that scholarship should be banished or even that study in depth should be made impossible but merely that premature specialization should be outlawed This is the central point in the report of Dr F S Dainton's committee on the recruitment of young people into science and technology He and his colleagues seem to have convinced themselves that the supply of technical people in Britain would be healthier if they were not invited to don intellectual straitjackets at too early an age More generally, however, the case for a broader curriculum must rest on broad educational principles The narrow curriculum in the British sixth forms is just plain wrong, and must be reformed Whether the outcome should consist of the study of four or five subjects, as Professor J T Allanson and Mr J S Morrison have suggested, or whether instead there should be a more rigidly broad pattern (as in France) or a general course of studies in which a variety of special subjects are embedded (as in the United States) is something to be argued out The plain truth, which no amount of experiment in the schools can conceal, is that there must be a radical change in the pattern

But what will be the consequences of these necessary reforms ? It is, of course, apparent that no radical upheaval in the sixth form would be possible without important changes in the pattern of higher education All kinds of unfamiliar possibilities are on the cards—four year courses, transformed and reformed public examinations, better means for helping students pick the careers that suit them best But most of what seem to be the complications of a broader school curriculum are probably necessary in their own right in any case

Science after the Cultural Revolution

CHINA's target in science, announced in January 1966, was to catch up, on a wide front, with the technologically advanced countries during the next twenty to thirty years The cultural revolution has changed these priorities—the new policy calls for a greater concentration of scientific effort on the problems peculiar to the development of China, and "self-reliance" seems to be the order of the day This was the picture of science and technology in China after the cultural revolution which Dr C H G Oldham, of Sussex University, pieced together, from reports in the Chinese press, in his Cantor lecture delivered last Monday to the Royal Society of Arts

It is beyond dispute that since the establishment of the People's Republic in 1949, the Chinese have been curiously reticent about publicizing their scientific and technological achievements and their expenditure on science and technology Information has been hard to come by and now the cultural revolution has almost completed the blackout No Chinese scientific journals have been received in Britain since October 1966, and the last British scientist to visit China on the Royal Society's exchange programme returned to Britain in November 1966 With announcements in the Chinese press as the only source of information, any assessment of the effect of the cultural revolution on science can at best be only fragmentary and highly subjective But even so it is worthwhile, and Dr Oldham has succeeded conspicuously well

Between 1949 and 1966 China appeared to be making steady if not spectacular progress in scientific development over a broad front The Government in Pekin clearly accepted that the development of economic and military strength depends on science and technology The Chinese Academy of Sciences, the Academy of Agricultural Science and the Academy of Medical Sciences were all expanded, and the explosion of nuclear weapons was a proof of capability in nuclear technology Great emphasis was given to science and technology at all levels of education, and it has been estimated that, by 1967, China had 1 3 million college trained scientists and engineers British scientists returning from China agreed that, on the whole, their Chinese colleagues were well-informed about science elsewhere and that they had a comprehensive supply of literature and an ample supply of domestic and imported equipment And with a few exceptions, such as the synthesis of insulin, the Chinese scientists seemed to be laying the vital, but necessarily unspectacular, foundations for long-term research programmes in basic and applied science No doubt more rapid expansion would have been feasible if senior scientists had not been so scarce As things have turned out, the only real distinction between the Chinese effort and that of other countries at a comparable stage in development has been the tremendous effort which the Chinese have made to teach science to the whole population, not just to an elite The Chinese believed this grass roots policy might lead to discarding old superstitions and to experiment and innovation at all levels of society No doubt there were failures but these were far outweighed by the successes

What has happened since the beginning of the cultural revolution in the summer of 1966 ? According to Dr Oldham, the Chinese Academy of Sciences and some of its institutes have suffered from the excesses of the revolution Fighting broke out in several institutes between supporters and opponents of the revolution The opponents, followers of Mr Liu Shao Chi, had gained the ascendancy in the academy in 1960–61 In Pekin in April 1967 they were accused of promoting research aimed at restoring what was ancient and worshipping what was foreign, of advocating research that was theoretical and divorced from the needs of the country, of supporting the award of academic degrees and scholastic titles such as "professor", and of asking for high salaries for scientists and special awards for those who had made special contributions By implication the pro-Mao group opposed all these policies

As a result of the revolution, a revolutionary committee now runs the academy, and for the first time the military is represented there But the former president and two vice-presidents have kept their positions and work has apparently gone on Several achievements in basic and applied science have been announced in the press since 1966 There has been an expedition of one hundred scientists to the area of Mt Everest, a large radio telescope—begun in 1958 but stopped by the pro-Liu group in 1960—has been rushed to completion ready for the period of intense solar activity in 1968, an all-Chinese digital computer has been developed and a new fossil skull of Pekin man found. It may be that the Chinese have also perfected a gas centrifuge technique for the production of uranium 235. Obviously, in spite of being larded with and attributed to the thoughts of Mao Tse Tung, both applied and basic science have continued through the upheaval. And Dr Oldham made the interesting point that there is nothing wrong with Mao Tse Tung's scientific maxims. When they are stripped of their jargon they boil down to such truisms as "Do not be overawed by what authorities in science say, be willing to challenge their beliefs". No one would quarrel with this. Naturally enough the maxims are aimed at the mass of a poorly educated population and they may not be a great benefit to well educated scientists, but they would not do much harm either.

But although science has not been stopped by the cultural revolution there has been a distinct change of emphasis. Any country in China's position trying quickly to apply science and technology to its economy faces two problems. What technologies are most appropriate for its stage of development and where should the technologies come from ? The country can either try to develop the most advanced technology, even though it is expensive and uses little manpower, or it can use less sophisticated technology and more labour. Equally it can import a technology or try to do its own research and development. As events in most developing countries have shown, striking the right balance between these alternatives is extremely difficult. Before the cultural revolution, China seemed prepared to import science and technology. As Dr Oldham interprets it, the main conflict of the cultural revolution, as far as science and technology is concerned, has been about the extent to which the Chinese should become self-reliant. If economic development were the sole criterion, the policies ascribed to Liu and his followers, who were prepared to rely heavily on imported science and technology, were probably right. But if total development—economic, social and political—is the aim, the self-reliance policy of the revolution makes sense. The new policy is more introspective and isolationist, but it is likely to result in a greater concentration of scientific and technological resources on problems primarily relevant to China's development. That is a loss to world science and to individual Chinese scientists who have lost some freedom of research and will no longer be competing on a world stage. For this reason it is crucial that formal contacts, such as between the Royal Society and the Chinese Academy of Sciences, be maintained and if possible expanded. But Dr Oldham is probably right in saying that, for China as a whole, what has happened may be a gain.

Future Foretold

from our Special Correspondent, Gif-sur-Yvette

THROUGHOUT this week an unusual meeting has been taking place near Paris. At an elegant chateau which forms part of the French National Centre for Scientific Research (CNRS) at Gif-sur-Yvette, experts from all over France—and some from other parts of the world—have been discussing what the world will be like in the year 2020. To keep the discussion within sensible limits, it has been set in a geographical context so that each day has been spent discussing the way in which different technological developments will affect the way land is used. It is clear that this meeting, known as the Symposium on Urban Planning and Advanced Techniques, is intended to be the first of a series which could, no doubt, last long enough for the results of this meeting to be compared with the reality of 2020. But the discussions in the past week have been more limited; they have been restricted to developed countries and have covered five broad topics—power and natural resources, data processing and transmission, communications and telecommunications, agriculture and rural space, and urbanization.

The inspiration for the meeting seems to have derived from Mr Jerome Monod, a French government official responsible for regional development and planning. But the origins are obscure, and it is probable that Mr Jacques Bloch-Morhange, a man with a catholic range of interests including, it is said, the breeding of racehorses, had something to do with it. Mr Bloch-Morhange is acting as secretary-general of the conference. The organizing committee of five, drawn from universities and government service, did most of the preparatory work which included commissioning studies by experts in the subjects concerned. The immediate practical benefit seems to be to help the French Government to formulate the Sixth Plan, but the organizers also see it as a way of helping administrators to avoid making decisions which are immediately overtaken by events.

The conference has been conducted at a philosophical level divorced in the main from immediate considerations such as those of finance. It was possible, for example, for the greater part of a discussion on the benefits of data processing to be completed before anybody asked if the financial investment in France would be great enough to sustain the hopes which had been expressed. But the discussion had not been futuristic—if anything the estimates of power and natural resources had erred on the side of conservatism. To be told that by 2020 half the electricity consumed would be generated by nuclear power, with the other half derived from hydrocarbon sources, astonished nobody. To this extent, the predictions have been unexceptionable, even unadventurous; but that they will help to formulate policies in the next five or ten years is undeniable. Much will depend on those who have to write the final report and draw together the results of what has been rather diffuse discussion. While it has been an interesting exercise, it is not immediately clear how the broad policy implications suggested by the week's discussion can be implemented in the face of the financial restrictions which normally determine events.

Donnish Productivity

BRITISH universities, enlivened no doubt by the scrutiny to which they are now subjected by the Comptroller and Auditor General, have been discussing the efficiency of their operations. To judge from the discussion among university delegates to a conference called jointly by the Committee of Vice-Chancellors and the Association of University Teachers on March 21, the cause of university productivity has made some worthwhile advances since the Committee of Vice-Chancellors first took an official interest in the subject two years ago. It is hard, however, to tell precisely how the universities reacted to some of the proposals now being made, for the universities seem to be as jealous of the privacy of their discussions as of any other academic freedom.

The conference on March 21 was opened by Mr C. F. Carter, vice-chancellor of the University of Lancaster and the British prophet of university productivity. The essence of his case was that teachers, and the way in which their work is organized, are more immediate limitations of the output of qualified students from universities than are buildings and other kinds of equipment, so that "increases of productivity are therefore most likely to be achieved by a better organization of labour or by harder work". Both in teaching and in research, according to Mr Carter, better productivity could be obtained by having fewer small departments, by not using highly trained staff for work that could be done by others, by spending more capital on educational technology, by organizing staff time more efficiently and by working harder. "And why not ? American academics do. It would help if more payment was on piece rates." Mr Carter would also like to see a redefinition of the division between teaching and research, and he considers that the more efficient use of buildings would make it possible for universities to double student numbers "even before using such obvious expedients as lengthening the very short teaching day". In Mr Carter's view, the university year should be organized on a staggered pattern with each student spending two out of three equal terms at the university each year. He wants to see more sharing of expensive equipment, a reduction of committee work and "a drastic reduction in the circulation of paper".

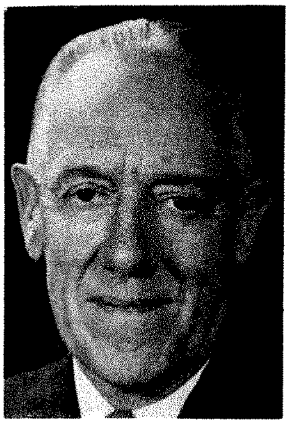
How did all this go down ? Several speakers at the conference were more concerned than Mr Carter with the philosophical definition of what is meant by university productivity. Something of this sort may eventually come from the work of Mr K. S. Davies, seconded to the Committee of Vice-Chancellors as a research officer, who is engaged on a long-term study of the factors which affect university productivity. Dr M. Blaug, of the University of London Institute of Education, took a still longer look at the problem of measurement, and was particularly anxious that the concepts of productivity and efficiency should not be confused. He would like there to be a continuing comparison of scores in student attainment tests at the beginning and at the end of university courses, studies by educational psychologists of the effectiveness of different teaching methods, more information about the socio-economic character of students and about their economic prospects, and some attempt to construct objective yardsticks for the evaluation of research.

It seems that only a minority of those present thought that studies of this sort were undesirable. One count showed that only three out of twenty-four speakers were against, with the rest in favour. This marks a great change of opinion in the past five years. It even seems to have been possible for Mr Carter to get away with the claim that university teachers in the United States work harder than those in Britain. Dr D. G. Christopherson, chairman of the Committee of Vice-Chancellors, said after the meeting that the universities did not feel themselves to be under immediate pressure. They were, he said, looking forward to the next period of fast expansion in the seventies. And the suggestion that the universities fear that if they do not begin to measure their own productivity, somebody less sympathetic will come along and do it for them was indignantly denied. Professor Blaug called it "an uncharitable suggestion".

Rockefeller Without Bronk

New York, March

THE resignation of Dr Detlev W. Bronk as president of the Rockefeller University later this year will amount to something like the end of an era in the affairs of the university, until 1964 the Rockefeller Institute. By common consent, Dr Bronk has been almost entirely responsible for the directions which the institute's growth has followed since his accession to the presidency in 1953 (after several years as president at Johns Hopkins). He has been consistently expansionist, with the result that the faculty has grown in size and lustre. He has also consistently fought for a recognition of the educational responsibilities of the people at the Rockefeller Institute, which is how the institute has acquired the distinction of being an independent university without undergraduates. Although there are few among the faculty who are unmoved by Dr Bronk's vision of the part his institution might play in the academic life of the United States, there have frequently been occasions when the president and the faculty have moved ahead at different speeds. The creation, within the past year, of an academic council at the Rockefeller University should help to ensure that the balance of power between the faculty and Dr Bronk's successor is more even.



There is no doubt that Dr Bronk's career is one of almost unparalleled distinction. For several years he has divided his immense energy between government and universities. His spell as president of the United States National Academy of Sciences, between 1950 and 1962, saw a vigorous growth of the academy's influence in Washington and elsewhere, largely as a result of the drive which Dr Bronk imparted to the job. In the circumstances, it is not surprising that Dr Bronk should plan not to settle back into retirement when his present appointment ends. He says that he will keep on a laboratory at the Rockefeller University, as is the custom for retired professors at the institution. At least until the election campaign is further advanced, he says that he intends to maintain a "flexible" position, which presumably implies that he will be ready to accept a call to another Washington job. In any case, Dr Bronk is personally deeply engaged in trying to bring science and technology to bear on the formidable problems of the city of New York. He says that a deeper involvement in social problems is one of his wishes for the future of the Rockefeller University. He would also like to see the institution become even more successful than at present at interdisciplinary studies.

Of Dr Bronk's successor at the university, there is as yet no news. Several distinguished names have been whispered in this connexion. There seems to be something in the view that Dr Frederick Seitz, now president of the National Academy, has been approached. It would, of course, be something of a feather in the university's cap if there were two examples to support the generalization that presidents of the academy habitually succeed to the presidency of the university.

De-specialization

A JOINT working party is to be set up by the Schools Council and the Standing Conference on University Entrance (SCUE) to examine proposals for broadening the British sixth form curriculum. The position of sixth formers not wishing to go on to university is to be investigated by a second working party which is to be set up by the Schools Council alone. The two parties will work side by side, with a possibility of overlapping membership. While welcoming the move towards broader curricula in schools, the universities see the Schools Council proposals for two A-levels and accompanying "elective courses" (*Working Paper* 16) as an encouragement to further specialization (see *Nature*, **216**, 1260, 1967). A meeting of SCUE last week collected together the comments of the universities and the announcement of the working parties soon followed.

As well as reducing specialization, reform of sixth form curricula will, it is hoped, delay the point at which pupils decide what subjects they will study at university. The universities see experimental curricula as an essential step towards reform, and are prepared to adapt their entrance requirements so as not to prejudice the chances of those pupils who act as guinea pigs. Current curriculum revision by the examining boards and the Nuffield Science Teaching Project is welcomed by the universities, but they would like to see further intensive studies of syllabus-making and examination techniques, with emphasis on the balance between facts, imagination, analysis and presentation. The universities express a doubt that "there yet exists any adequate alternative to externally examined courses as the main basis for sixth form preparation, and selection, of entrants", but at the same time suggest that the "introduction of an element of internal assessment into the examining system merits consideration". A scheme for four or five equivalent two-year courses spanning arts and science subjects is suggested as worthy of experiment, despite teaching difficulties and the resulting lowering of final examination standards. Following on from this the question arises whether an appropriate first degree standard can be reached in three years.

On the basis of this combined view, the universities are joining with the Schools Council to discuss all the proposals so far put forward. The second working party will be concerned with sixth formers not intending to go to university, with regard for qualifications required by industry and commerce. A successful curriculum will obviously have to cater for those both above and below the academic salt, so that pupils are free to decide on their future during their last year at school.

Other aspects of the move away from specialization were discussed at a meeting at Queen Elizabeth College last week of some 140 sixth form science teachers and a sprinkling of university staff. Dr J. E. Spice from Winchester described the workings of the Nuffield physical sciences A-level course which is now on trial in 58 schools throughout the country. In combining chemistry and physics as one A-level subject, the physical science course allows biologists, for example, to take mathematics within the three A-level pattern. The overall comment on the joint course was favourable, from both schools and universities, despite strong words from some quarters—notably from Dr E. R. Roberts of Imperial College, a chemist who regretted the dearth of chemical facts in the course. From the physics side at Imperial College, Dr H. J. Pain retaliated in favour of students who have taken this course, preferring their ability to think to a stream of well-learned facts. There were murmurs from chemistry staff who are beginning to teach the physics side of the course to the effect that they themselves can at last understand the physics they learnt at school.

The new London BSc system, now in its second year, allows students to delay their final choice of subject until the end of the first year. Professor R. E. Burge of Queen Elizabeth College described last week the workings of the system of equivalent course units and the possibilities of inter-college co-operation. By giving each college more control over its courses, the new system is more flexible and adaptable to new knowledge. With a minimum of eight of the equivalent units to be passed for a degree and a maximum of twelve, the new course provides for the wide range of ability now found in universities.

Where To Put It

As everyone had expected, choosing the site for the CERN 300 GeV synchrotron is proving to be an extremely touchy business. Nine countries have offered sites but no decision was reached at the last meeting of the council of CERN which discussed the recently published final report of the Site Evaluation Panel. The panel, consisting of three neutral representatives from countries which had not offered sites, has been working on the report since its appointment in 1966, and a separate geological survey of the sites has been prepared by Dr L. Bjerrum of Norway.

Based on the answers to the three questions of whether this laboratory can be built at the site (A), whether it can be operated there (B) and whether people will go there (C), the panel concludes that Doberdò in Italy is the most suitable location. Le Luc in France is second best and the other sites all less suitable. (See table.)

With the future development of CERN likely to hang on the choice of site for the new accelerator, the panel is understandably cautious in its report. It points out that none of the sites is ideal by all three criteria, that several are perfectly acceptable and that a different set of criteria might change the order The report stresses, however, that the acceptable sites are not of equal value

RATING OF REPLIES TO QUESTIONS A, B AND C

Site	A	B	C	Overall rating
Gopfritz—Austria	γ	γ	γ	γ
Focant—Belgium	γ	β	γ	γ
Drensteinfurt—Germany	β	α	γ	γ
Le Luc—France	α	α	β	β
Aspropyrgos—Greece	δ	δ	γ	γ
Doberdò—Italy	γ	α	α	α
El Escorial—Spain	β	γ	γ	γ
Uppsala—Sweden	α	β	γ	γ
Mundford—Great Britain	γ	β	γ	γ

Needless to say, the report has been accompanied by what amount to special pleadings from the delegations of the disappointed countries The Spanish delegation called for a widening and revision, the Greek delegation contests the view that Aspropyrgos cannot be considered because of the risks of earthquakes, the Austrian delegation disagrees with the geological survey of Gopfritz and the British delegation holds that the cost of construction and operation should be the most important criterion

Back to Chicago

THE capability of the National Science Foundation to hold its own in Washington will be further diminished, in October this year, by the departure of Dr John T. Wilson, at present deputy director at the foundation, for the post of vice-president at the University of Chicago In the past five years, Dr Wilson has become known as a powerful source of new thinking about the policies of the National Science Foundation, and there will now inevitably be speculation that his resignation has been prompted as much by the frustrations of his work in Washington as by the attractions of Chicago

Since the war, Dr Wilson has alternated between the foundation and Chicago He was assistant director for biological and medical sciences at the foundation from the mid-fifties until 1961, when he became a professor of psychology at Chicago and special assistant to the president of the university, Dr George Beadle In his new post as vice-president of the university, he will be responsible for the academic administration If his experience and temperament are any guide, he will expect to play an important part in the development of a strategy for the development of the university under its new president-designate, Dr Edward Levi

Dr Wilson's departure from the foundation may well bring into the open some of the continuing doubts about the management of the foundation which are now widely shared among scientists in the United States There is much to support the view that the direction of the foundation has been less than adequate since its establishment in 1950 For the first decade or so, under the late Dr Alan T Waterman, the foundation was perhaps unduly and unwisely preoccupied with the problems of support for fundamental research, and too little concerned with the relations between research and education on one side and government on the other More recently the foundation s influence seems to have been needlessly muffled On one view, the continuing ill-health of the present director, Dr L J Haworth, is a part of the trouble Elsewhere it is held that a more thorough recasting of the hierarchy at the foundation may now be necessary

Postgraduate Biologists

THE report of the biology sub-committee of the committee of the Royal Society which is surveying postgraduate training in science and technology, the third of six, has just been published Faced with the problem of surveying the multitude of specialized disciplines which came under the umbrella of biology, the sub-committee, under the chairmanship of Professor J L Harley of Sheffield University, decided to collect evidence in four ways It read the propsectuses and proposals of the universities It sent a questionnaire to the heads of departments and research stations (167 replied), and some heads of departments were also interviewed The sub-committee sent another questionnaire to people who had gained their PhD degrees in the past five years from five universities Finally, the committee obtained descriptions of PhD programmes in North American universities from senior biologists who also knew the conditions in Britain Clearly, compared with the physics sub-committee which based its report entirely on the replies of heads of departments to a questionnaire, the biology group has spread its net wide

What are the conclusions ? The report says that "British systems of PhD training in biology are designed essentially for the candidate who is well prepared by his first degree for research and whose success depends principally on his own initiative and that of his supervisor The systems are not so appropriate to those candidates who are less well prepared, nor to some students from overseas" That sounds like a polite way of saying that there are no organized programmes for training PhDs but rather an apprenticeship system in which making a shrewd choice of supervisor at the outset is vitally important This is borne out by the two recurrent themes in the suggestions for improvements sent to the sub-committee They are, first, to improve the system of supervision and, second, to increase the number of lectures and seminars for postgraduates

Altogether, 90 per cent of the recent PhDs recognized that some formal instruction is now necessary, but fewer than 10 per cent of the 167 departments in the survey run lecture courses specifically designed for postgraduates The most favoured proposal, which the sub-committee endorses, is for unexamined lecture courses and surveys spread over the first two years of postgraduate study And, because the standard of the first degree is usually higher in Britain than in the United States, such courses need not be on the scale of those in American PhD programmes In contrast with the views of recent PhDs, the senior staff of 40 per cent of the departments consulted were against formal instruction They no doubt fear the extra teaching load and, as the report points out, the chief reason for the present situation is the small size of most departments, the staff of which is fully committed to undergraduate work This, coupled with the small numbers and diverse interests of postgraduates, often makes special postgraduate courses impracticable and uneconomic The sub-committee is obviously right in saying that closer interdepartmental collaboration is the answer to these problems

The sub-committee has also unearthed figures which show the alarming, in fact disgraceful, paucity of seminars and colloquia in biological departments Only 78 per cent of the departments hold seminars during term—18 per cent weekly, 18 per cent monthly and the rest presumably less often That 82 per cent of British biological departments only average at best a monthly seminar, and that 22 per cent apparently have no regular seminars at all, speaks for itself Small wonder that the report urges that such meetings, which are vital for any thriving department, should be more frequent and inter-departmental where possible

"Good supervision is the keynote of a good PhD system " It is typical for the postgraduate student to see his supervisor several times a week, if not daily

The sub-committee considers that "supervision cannot be improved fundamentally by legislation" but nonetheless it says it would be useful to formulate minimum requirements for meetings between students and supervisors In its subdued way, it also proposes that having committees of three to five supervisors, as is common in the United States, should be considered This system exposes the postgraduate to a wider range of factual knowledge and, more important, to a wider range of experimental skills and approaches without necessarily excluding the personal responsibility of one supervisor for one particular student Indeed, where there is a clash of personalities, the committee system would be an enormous improvement As things are, it is extremely difficult for a student to change his supervisor, no matter how badly they get along with each other

As to the PhD examination itself, although there is concern, especially among recent PhDs, that the standards of the degree and the methods of examination are too variable, the report makes no recommendation for change Arguments for and against the supervisor being an examiner, and whether or not all examiners should be external, are equally balanced, and most departments were not in favour of classifying the PhD degree except for possibly giving a mark of distinction to outstanding theses It seems that 99 per cent of PhDs in biology are completed in three years and only 1 per cent take longer, so the sub-committee, unlike the physics sub-committee, does not recommend provisions for fourth year grants Again in contrast to the physics sub-committee, the biologists believe that, so long as standards are not diminished, changes in the present three year honours degree are not necessary The first degree in biology apparently still provides a satisfactory grounding for PhD training

Old Age

RETIRED people now make up more than 12 per cent of the population of Britain During this century the four-fold increase of people in this age group has far outpaced the increase in lower age groups, although the life expectancy of a 65 year old has only increased by 2 years, while that for a baby has increased by 24 years More than three-quarters of the 300,000 old people who live alone do not have the help at home which they think they need and many thousands are in need of medical attention The Office of Health Economics (OHE) has been studying the facts, figures and problems of old age and makes suggestions as to how the lot of old people can be improved, in its latest paper *Old Age* (OHE, 2*s* 6*d*)

The main priority, the report suggests, is to improve the quality of old people's lives rather than to prolong them At present, care of the old costs more than £1,650 million a year in Britain, £400 million of this being medical care which takes 30 per cent of the National Health Service budget Healthier old people will not only mean happier old people, but a lighter burden on the community If people over 65 become generally healthier, the retiring age could be raised Two particular lines of approach are discussed in the report—the provision of better welfare services for those who are now old and further attempts to prevent illness that will incapacitate people when they get old. Research is required in both directions As well as the obvious investigations into disease and the nature of ageing, the sociological effects of old age must be studied in connexion with housing, health and ignorance of how help can be obtained The OHE recommends that a national council could be set up to co-ordinate the various aspects of research, as a multidisciplinary approach would be most effective

The OHE, sponsored by the pharmaceutical industry, is an independent organization which undertakes research on various economic and social aspects of medical care *Old Age* is its twenty-sixth publication, earlier papers having covered such topics as mental health, polio, drug addiction and medical manpower The director of OHE, Mr G Teeling-Smith, suggests that although the study of old age has less glamour than work with children, it can improve the quality of the retirement years that face us all

Defence Research

from our Parliamentary Correspondent

WITH three public sessions gone, and perhaps twice as many in private, the Select Committee on Science and Technology has learned one thing at least· the civil servants responsible for defence research are unanimous in their approval of the way it is done. Mistakes, it seems, are a thing of the past, banished by the adoption of the Gibbs–Zuckerman procedures, as the techniques of assessment are called This may be true, but the committee would be doing less than its duty if it believed it without independent corroboration Unfortunately, all those who are familiar with the system have an interest in saying how good it is What the committee needs is a company disenchanted with the Ministry of Defence During the most recent session, on March 21, a possible candidate emerged—the hovercraft industry, which seems to have met with little encouragement from the ministry

On March 21, the committee interviewed five representatives from the ministry Most of the questions were on organizational minutiae—the operational requirement committee, eight strong, meets weekly, while the weapons development committee, nineteen strong, gets together every fortnight The witnesses agreed to supply three case studies showing how three projects came to fruition—the CVRT armoured vehicle, the Nimrod aircraft project, and the Type 42 destroyer.

They were confident that good ideas, whatever their origin, got a fair hearing, and that bad ideas could be weeded out before they had gone too far. Some members of the committee suggested that the only pressure brought to bear on the projects was financial pressure. The witnesses agreed that financial pressure alone was enough to put a heavy constraint on defence research, but in addition there was an automatic weeding process.

Mr Eric Lubbock suggested that the British hovercraft industry had had less than fair treatment from the ministry. Although they had made a number of proposals, few had been taken up. Mr Stuart Watson, for the Navy, agreed that the industry had been "pestering us with ideas". The result had been to agree to the building of BH7 hovercraft for the Army and the Navy, although the Army version had now been cancelled because of the withdrawal from the Far East. As for bigger hovercraft, they would have to be shown to fulfil a real military requirement. Mr Lubbock thought this an extraordinary answer. Would the hovercraft not be suitable as a search vessel for submarines, or as a fast armed vessel? The witnesses reiterated that all possible had been done to help the hovercraft industry.

London's Water

The bacteriology, chemistry and biology of London tap water are subjects which most Londoners must prefer not to have to think about when they drink their morning cup of tea. A great deal of work, however, has to be done before the water from the River Thames and the River Lee is even remotely drinkable and stringent standards are operated to make tap water as pure as possible. Some of the routine and research work done by the Water Examination Department of the Metropolitan Water Board during 1965–66 to achieve these standards is described in the forty-second report of the department just published (Metropolitan Water Board, 32*s* 6*d*.).

Continuous sampling and testing is carried out to check the quality of supplies. In 1966 almost 133,000 samples were dealt with—the highest number of samples ever handled by the department. "Ideally all waters intended for drinking should show no coliform bacteria in 100 ml. and it should be the aim of every water undertaking to provide water of this quality", according to Report No. 71 of the Ministry of Housing and Local Government and the Ministry of Health. London water seems to pass the test—out of more than 11,000 samples of treated water leaving the board's filtration works and well stations in both 1965 and 1966, 99.98 per cent were 100 per cent bacteriologically pure as far as *Escherichia coli* was concerned. Results of the coliform test were not quite as good in 1966 as in 1965; 99.68 per cent of samples were free from coliform bacteria compared with a percentage of 99.88 in 1965. This slight decrease in purity can probably be explained, the department says, because a more sensitive test for the isolation of coliform bacteria was introduced at the beginning of 1966.

Detailed descriptions of the work of the various sections of the department are given in the report. The bacteriological section has been continuing its examination of water for *Salmonella* organisms; their presence in the water after storage and primary filtration and on the surface of slow sand filters suggests reinfection of the water by gulls. *Salmonella* organisms have also been isolated from detergent foam. The chemistry section has found that there has been a reduction of the residual amounts of synthetic detergent material in the board's river sources of supply after the complete substitution in packets of washing powder retailed in Britain of anionic detergents which are biologically degradable.

An important part of the department's work is concerned with public health, such as the examination of waterworks employees for the detection of carriers of waterborne diseases. It was reported in the previous annual report that a case of bilharzia had been found among the board's employees, and this has prompted speculation as to whether the disease could possibly spread in Britain. It is thought unlikely but not impossible, and a note of warning is given on the careless introduction of snails—the intermediate hosts for the helminth parasite *Schistosoma*—from countries where the disease is endemic.

No More Noise?

From July this year, British motorists will be subject to yet another roadside spot check. At present drivers have to proceed soberly, in a safe vehicle and at a moderate pace, but by the summer they will have to be quiet as well. Although the regulations announced this week by Mrs Barbara Castle, Minister of Transport, put the maximum allowed decibels at higher levels than those recommended by the 1962 Wilson Committee on Problems of Noise, the limits are experimental and may well be lowered in the future. Noise meters will be used in much the same way as the radar speed checks, with police stopping the vehicles which pass the set limits—90 db for motor cycles over 50 cc, 87 db for passenger cars and 92 db for heavy goods vehicles, agricultural vehicles and buses. During the initial period drivers of lorries with burnt-out silencers and car fiends with "organ-pipe exhausts" will be cautioned only, but later on, offenders will be liable to fines of up to £50 for a first offence.

The noise meters are said by the Ministry of Transport to be very accurate. They will be calibrated by approved laboratories and checks will be made from time to time against gadgets with standard noise output. A three decibel allowance is made in the noise limits for roadside tests to allow for such things as sounds reflected from other vehicles. From 1970, all vehicles will have to be constructed in such a way that they do not exceed the noise limits when tested at full throttle. The two year time lag is being allowed to give manufacturers time to adapt their models.

Golden Touch

The Royal Institution launched last year an appeal for £225,000 and did it so successfully that £270,000 has already been received and the money is still coming in. The donors include some 300 foundations, companies and individuals. The money is to be spent on building a new lecture theatre and museum, renovating the present theatre and laboratories and expanding the institution's educational facilities.

The Royal Institution was founded in 1799 by a native of Massachusetts, Count Rumford, for the promotion of science and the diffusion and extension of useful knowledge Among its resident professors have been Davy and Faraday, and its present director is Professor George Porter The current functions of the Royal Institution, as Professor Porter explained last week to the clinking of champagne glasses, are to serve as a society for the advancement of science, as a national archive for the history of science, as a theatre for scientific lectures and meetings and as a research laboratory The enviable success of the institution's appeal will no doubt help

Computer Control

In the future, British industry will apply computers to production and stock control to the same extent as they are now used in accountancy This was the theme of a symposium organized by the British Computer Society in London on March 20 More than 1,000 delegates heard from British and American experts how computers can be applied to the scheduling of production on the shop floor, to the control of materials needed in the manufacturing processes and to the efficient stocking of the finished product

There still seems to be a variety of pitfalls in the introduction of computers into production control—not the least the problems associated with people One of the speakers pointed out that two of the commonest mistakes made by management are the failure to take into account the limits of comprehension of employees and the neglect of those parts of the control system which are placed outside the computer This means that more attention needs to be paid to gathering data for the computer, and to the way in which the computer output is used by management and personnel on the shop floor And, not unnaturally, there is always the lurking fear that people are being replaced by machines

Several delegates to the symposium seemed doubtful whether computer production and stock control systems had reached the stage of making themselves pay There seems to be no clear-cut answer to this—obviously it is difficult to estimate the financial saving made by benefits such as less capital tied down in stock and work-in-progress, better delivery dates and so on which are claimed by advocates of computer systems Nevertheless, more and more manufacturers are turning to computer systems, especially in the United States, which is clearly showing the way in this field

One of the questions which the symposium tried to answer was whether the smaller firm should go in for production control by computer when big organizations are obviously running into difficulties in this field Mr B G Roberts, computer development manager for Belling and Lee Ltd, defined the smaller firm as one with less than £60,000 per annum to spend on data processing during the first few years of operating a computer He made the point that although the amount of data to be dealt with is less than in a larger company, the number of processes through which the data has to go may be just as great Because the data handling procedures rather than the bulk of data provide many of the problems, and because big organizations have the resources to handle large amounts of data, it seems that small firms are less likely to be successful in introducing a computer than large ones

Nevertheless, the chairman of the symposium, Mr W G E Hulse, who is manager for production planning and material control at Standard Telephones and Cables, said in his summing-up that the emphasis in the future will be on the smaller companies Because there are common ingredients to the production problems of many companies working in the same field, there is a need for co-operation in setting up computer centres This poses problems in the security of business information but, as Mr Hulse pointed out, companies already rely on the confidential nature of bank accounts so why not trust computer centres in the same way ?

New Ideas

The emphasis was once again on the small firm at a conference with the title "Getting New Ideas off the Ground" held in London on March 21 Arranged by the Institute of Directors in association with the National Research Development Corporation, its aim was to tell senior management about the NRDC and the way it can help industry The NRDC was set up in 1948 after it was realized how much had been lost by the failure fully to exploit commercially the discovery of radar and penicillin as well as many other discoveries pioneered in Britain Its aim is to provide support for technological developments of potential commercial importance and to encourage industry to adopt new methods and products invented in government and university laboratories and elsewhere

Sir Donald Stokes, chief executive and deputy chairman of British Leyland Motor Corporation, said in his opening address that no firm, however large or however small, need have any hesitation in putting its problems to the NRDC for consideration He admitted that management was still far too stuffy about new ideas and was reluctant to give revolutionary thoughts a trial

The message of the conference was that small firms should not be reticent in using the NRDC Clearly large companies are aware of the NRDC and several of them are using its facilities, but the organizers felt that the functions of the NRDC needed emphasizing to the smaller firm

Data Centre for Oceanographers

The Natural Environment Research Council is to set up a British Oceanographic Data Service at the National Institute of Oceanography, Godalming The head of the unit will not be appointed for another three months or so, but a steering committee of nine members has been announced and it had its first meeting last week The chairman of the steering committee is Dr G Deacon, director of the National Institute of Oceanography As with many other subjects there is an increasing amount of data which needs handling in a systematic way It is hoped that the centre will use modern methods of data storage—punched tape, a computer, and so on, and that it will have telex links with other oceanographic and research institutions

This will not be the first oceanographic data centre in the world There is one at Copenhagen run by the International Council for the Exploration of the Sea, and others in Hamburg and Ottawa, for example The idea now is to have national data banks co-ordinating with one another instead of world centres There is a small oceanographic data centre in existence in Britain at the moment, but this is for bathythermographic data only and it is run by the Ministry of Defence (Navy), Hydrographic Department The new national centre will cover all oceanographic data from the area of the north-east Atlantic and the North Sea down as far as the bay of Biscay To start with, the centre will collect data on physical oceanography only—temperature, and salinity measurements and so on, but eventually it will store and disseminate information in the whole field of oceanography

Spina Bifida Appeal

AN appeal for funds was launched last week by the Spina Bifida Trust (112 City Road, London EC1) Children born with spina bifida, most of whom have hydrocephalus as well, and those with hydrocephalus only, are now surviving in increasing numbers In Britain there are about 8,000 such children under the age of 16 and their numbers are being added to at the rate of about 900 a year

Spina bifida is a deformity of the spine in which there is a split in the spinal arch, this causes the nervous tissue to lie exposed on the surface of the back at birth Some of the nerve cells have not developed properly and the split spine renders them liable to damage, with the result that there is often partial or complete paralysis below the level of the defect This may affect bladder and bowel control as well as muscles of the limbs

The development of a valve system for treating hydrocephalus, which occurs in most cases of spina bifida, has made treatment of the rest of the disability worth while Because of their paralysis the affected children require special education and training Funds are needed to supply these facilities and to conduct further research into the causes of the condition and its treatment

Operation Habitat Rescue

WILDLIFE in agricultural areas is continually threatened as more hedgerows, copses and banks are removed under the pressure of farm mergers, monoculture and more mechanization To try to reverse the disappearance of wildlife in farming areas in Britain, a Conservation Corps Habitat Rescue is being organized by the Soil Association and the Council for Nature Young volunteers will try to help the survival of wildlife by conserving hedgerows and banks, ponds and ditches, and planting small copses as refuges The scheme has been made possible by the Jack and Mary Pye Trust, which is supporting the Soil Association's participation It is hoped that proper hedge management will not only create and preserve habitats for wildlife but that it will be of direct benefit to farmers in helping conservation of soil fertility and ultimately long-term productivity In many parts of the country removal of hedges has led to quite severe soil erosion by wind, in addition to drastic reduction of some species of animals and plants

Conservation Corps volunteers will work first on the 200 acre experimental farm of the Soil Association in Suffolk Later, it is planned to extend the work to selected areas of wasteland in other parts of Britain

Parliament in Britain

European Technological Collaboration

MR A WEDGWOOD BENN, Minister of Technology, refused to make available a report of the inter-departmental committee meetings on European Technological Collaboration at the request of Mr E Moonman (Billericay) Mr Moonman wanted to know how many meetings of the committee had taken place and urged Mr Benn to make a statement on the future work of the committee. Mr Benn agreed that reports of such committees would be attractive, but suggested that it would make government impossible, and that it would lead to the additional problem of secret meetings of officials to avoid the risk of publication (Oral answer, March 18)

Pharmaceutical Products

MR E J MILNE (Blyth) asked Mr K Robinson, the Minister of Health, to set up Government-owned factories—preferably in development districts—for the manufacture of drugs, pharmaceuticals and other commodities required by the National Health Service Disappointed by the minister's negative reply, Mr Milne stressed the need to look more closely into the matter, adding that pharmaceutical costs "will loom very large in our prices policy in the near future" Also addressing the minister, Mr Maurice Macmillan (Farnham) asked him if he would bear in mind the record of the pharmaceutical industry which has increased its exports about five times since 1948 and which now stands at a net export figure of about £75 million (Oral answer, March 19)

Medical Computing

MR DAVID CROUCH (Canterbury) asked the Minister of Health what plans he had to implement a national plan for medical computing Mr John Hunt (Bromley) was also interested to know what discussions the minister proposed to have with the computer industry regarding the use of computers both in the medical field and for improving the general administration of the National Health Service He tried to find out whether the minister could give any indication of the financial savings from the wider use of computers within the Health Service Mr Robinson replied that discussions were continually being held with computer manufacturers, but he was unable to give any information on Mr Hunt's second point (Oral answer, March 19)

Aldermaston

As usual, Mr Tam Dalyell (West Lothian) had something to say about the type of work done at defence establishments He tried to ascertain what steps had been taken to declassify work at the Atomic Weapons Research Establishment, Aldermaston, and asked if research for commercial purposes was being promoted there Mr Benn said that it had always been the practice at Aldermaston to declassify work as far as possible and to publicize the work extensively He added that, for the past five years, a large part of the site had been an unclassified area Dr Jeremy Bray, Joint Parliamentary Secretary to the Minister of Technology, emphasized that the establishment accepts many orders on commercial terms from government departments and from private customers for research and development outside the atomic weapons field (Oral answer, March 18)

British Schools to go Metric

by

NIGEL HAWKES

THE way in which British schools should adopt the metric units of the Système Internationale was the subject of a one day meeting on March 20 at the Royal Society. As a number of speakers pointed out, it is now no longer a question of whether but of when and how the change is made. The British Government is committed to a complete changeover of units by 1975, and it is becoming increasingly urgent for teachers to be made aware of the change and at the same time given guidance about teaching the new units. As with so many educational changes, the common view seems to be that the new units, as well as bringing Britain into line with most of the world, also offer a splendid educational opportunity if teachers had the courage to seize on it.

Mr Arthur Wynne from the Ministry of Technology and Dr D. H. Sharp from the Confederation of British Industry outlined the progress so far made in industry. It seems that the problems posed by the retail trade have yet to be solved, and Dr Sharp confirmed the report (*Nature*, **216**, 1157; 1967) that the CBI had recommended the formation of a metrication board, to coordinate planning, conduct a massive publicity campaign and arrange for financial assistance. The recommendation has been processed by Mr Wynne's Joint Committee on Metrication, and is now filtering through the machinery of government.

Delegates at the meeting, representing education authorities, schools, learned institutions, teachers, associations, examination boards and the Publishers' Association, agreed that SI units should be the only units permitted in Ordinary level mathematics and science "As soon as possible, and in any case not later than June 1972". The recommendation is to be passed on to the examination boards. The meeting also agreed that "September 1969 should be the date for a change of emphasis in teaching in the primary schools".

A number of speakers at the meeting spoke warmly of the educational benefits of the change. Dr E. D. Tagg, of the unhappily named Accelerated Teaching of Higher Level Mathematics Project at the University of Lancaster (and a former teacher at Oundle School) said that he thought the saving of teachers' and children's time would be worth £100 million a year. Mathematics was unpopular, he said, because at the moment it contained "a maximum of labour and obscurity". Metrication would not be the answer to all Britain's educational ills, but it was a natural and wholly desirable step. Mr F. C. Brown, of the Institute of Education at the University of London, thought that, to be successful, metrication needed a bold touch; it was no good running both systems in the schools at once. "Dualism could be the ruin of the whole process." Other speakers contested this view, but there was a considerable measure of agreement with Mr Brown's view that the examination boards held the key to success.

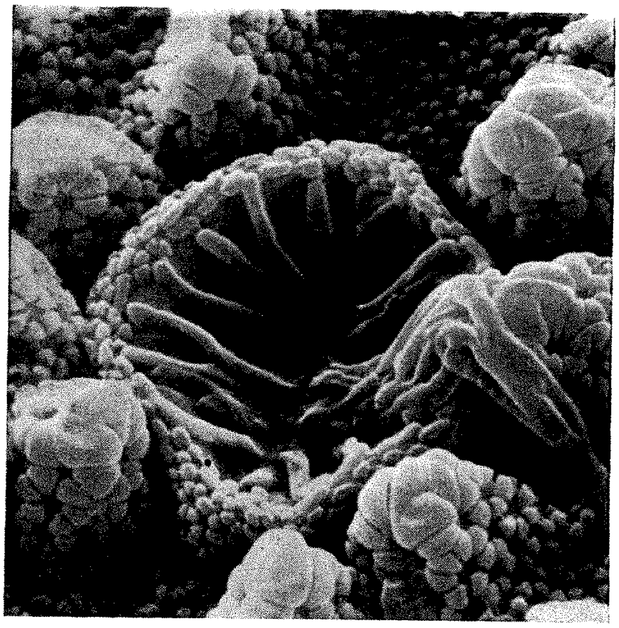
Representatives from the examining boards took a much more cautious line. Their argument was that the examining boards should follow the schools, rather than try to lead. Mr A. E. E. McKenzie, secretary of the Oxford and Cambridge Board, said that the boards were not authoritarian. The Advanced-level examinations would not present a problem, and would all be set in metric units in the next two to three years. Ordinary-level examinations would be harder to deal with, but Mr McKenzie suggested that mathematics and science examinations should be set in the metric system by 1975. Most of the other delegates thought this a depressingly unambitious target, and said so; one pleaded with the boards to be more dictatorial, another suggested that they should take less notice of what the universities said. The upshot was a firm request by the schools that the examination boards should fix a timetable and stick to it.

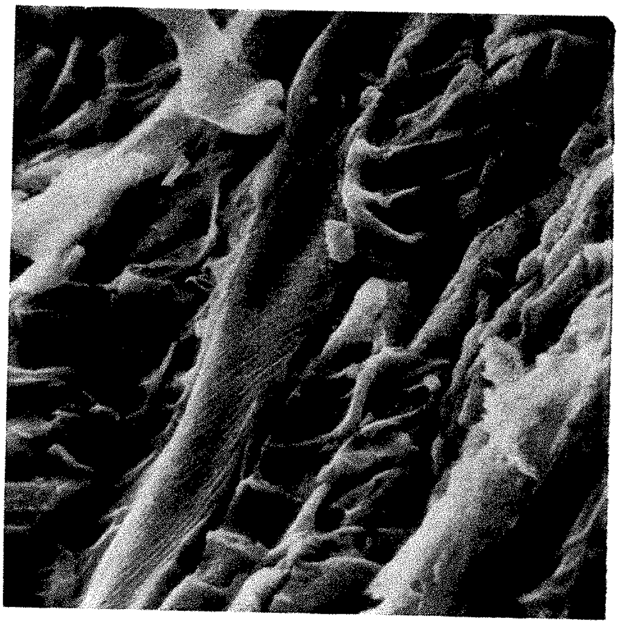
Mrs E. M. Williams, a former principal of Whitelands College of Education, gave a lucid account of how the change would affect the primary schools. She was optimistic, she said, principally because of the changes in teaching which have transformed primary school teaching in the past few years. In particular, the way in which children are now taught to understand numbers by the use of structural apparatus could readily be extended to the teaching of units.

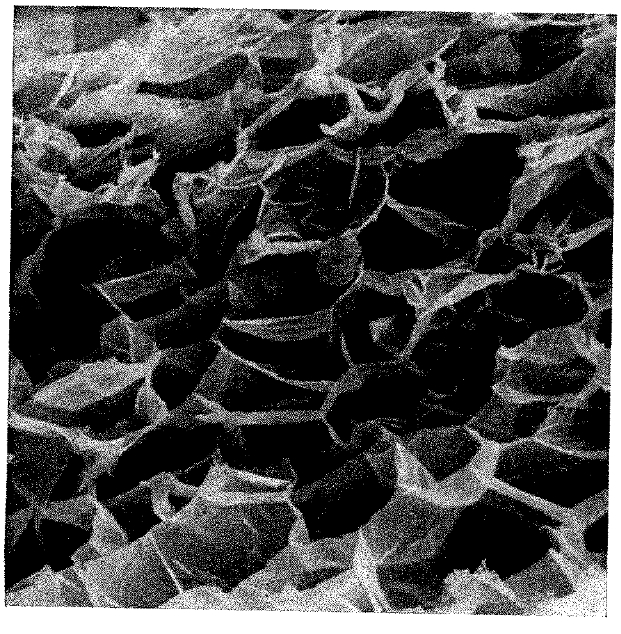
Various speakers from the Publishers' Association expressed alarm about the supply of textbooks. The most urgent need, Mr W. G. Clouter suggested, was for a definite timetable which would enable the publishers to plan ahead. But he was also concerned about the financial aspects of the change of textbooks; would the schools be expected to buy the new books out of their normal capitation allowance ? This was already under strain, he said, and it seemed to him necessary for more money to be made available. Other speakers from the Publishers' Association put the same point more strongly; one pointed out that there were 30,000 textbooks in print. If special grants were not made available, the new SI books would mop up too much of the capitation grant. Most delegates agreed, however, that the revision of textbooks and the writing of new ones would provide an opportunity for a much needed improvement in standards.

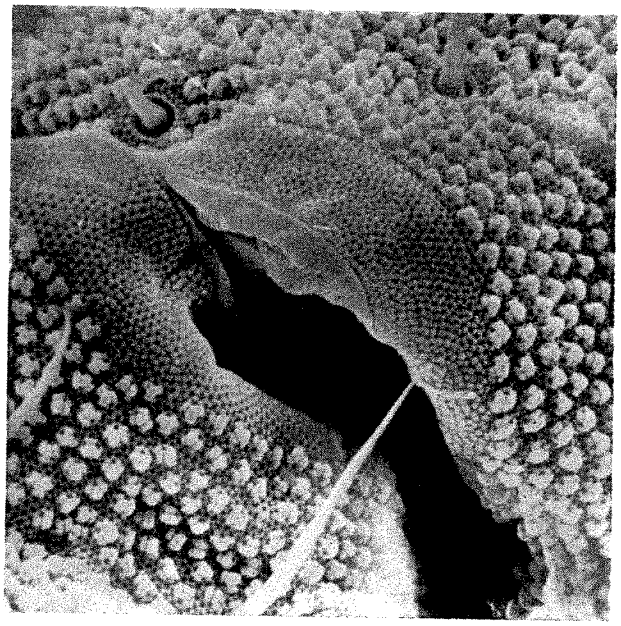
There was some discussion of the ways in which the change could be publicized. Mr R. Sibson from the Schools Council said that the council would soon be publishing a pamphlet for distribution to schools. Professor M. J. Lighthill, who ran the meeting with great skill, suggested that the Royal Society itself might produce a pamphlet, and there was some discussion of a draft pamphlet which the society has already drawn up. There was some feeling that two pamphlets, one for primary and one for secondary schools, would be better, but this, Professor Lighthill said, depended on the resources of the society. After agreeing to submit recommendations to the examination boards, and producing under Professor Lighthill's guidance a suitable form of words, the meeting decided to meet again in September for further discussion.

Scanning Electron Microscope Pictures









Top left : Pseudocellus of *Onychiurus scotarius* of the order Collembola ("springtails"), magnified 6,000 times (Drs W. G. Hale and A. L. Smith).

Bottom left : Expanded polystyrene, coated with a 500 Å layer of gold/palladium, magnified 180 times.

Top right : Fragment of coal with inclusion, possibly metallic, magnified 1,500 times.

Bottom right : Entrance to ventral tube of *Onychiurus scotarius*, magnified 2,300 times (Drs W. G. Hale and A. L. Smith).

Scanning electron microscopes with useful magnification of up to 50,000 and depth of focus 300 times better than that of an optical microscope for similar magnification have been commercially available since 1965. These microscopes, which cost £20,000, have evolved from the research work of Professor C. W. Oatley and his group at Cambridge. The resolution of the present version varies with the operating mode from 150–300 Å to 1000–2000 Å. A beam from a conventional triode electron gun is focused by three pre-aligned electromagnetic condenser lenses to give a fine probe which scans the surface of the specimen.

(Micrographs from the Cambridge Instrument Co.)

NEWS AND VIEWS

British Computer Merger

AFTER eight years of mergers and takeovers, the British computer industry is now under a single management The finalists, International Computers and Tabulators, English Electric and the Plessey Organization, announced last week the formation of a combined company, International Computers Limited, which will be the largest manufacturer of computers outside the United States The spur of American competition has been the principal factor in this process, and no doubt the Ministry of Technology hopes that by doing to computers what has already been done to cars and electrical engineering, it has added another arrow to its Common Market quiver, Indeed, Mr Wedgwood Benn seemed to be pointing his bow at France's failure to protect her computer industry from the American onslaught when he described in January to the Council of Europe the "increasing dominance of European industry by the Americans, this has been so marked in some industries that there must be doubt as to whether these indigenous European enterprises can survive unless there are determined efforts to bring the fragmented entities together to form continental-sized undertakings"

In theory, at least, the unification of the British computer industry is probably wise, and the Ministry of Technology has expressed its confidence in the scheme with £17 million of public money, of which £13½ million is a direct grant for research and development In practice the merger is also a marriage of necessity, not just convenience, and the new company has formidable problems to surmount before the benefits of size become apparent The merging of two groups of people performing more or less identical tasks is likely to be painful and time-consuming The principal ranges of machines produced by the two partners are largely incompatible with each other and much ingenuity will be necessary to devise a new range of saleable computers

The new company will need to mount a considerable research effort, and to be accorded a considerable measure of luck, if it is to achieve this aim The one clear finding that has emerged from the numerous studies of industrial research and invention is that there is no royal road to success In spite of the great size of the new company, there is bound to be some anxiety about its capacity to carry out research on the scale which circumstances probably now require If it really intends to keep up with the IBMs of this world, International Computers Limited will have to change not merely the scale of its research and development but the character as well The strength of the great American companies in computers and communications stems from the way in which they straddle the whole field of innovation Not merely are they thus well placed to take advantage of whatever new developments may fortuitously suggest themselves, but they are also able to impose their own pattern on the development of technology It will be interesting to see how long it takes the new British company to weld together the hotchpotch of research facilities which it has inherited into a single coherent unit, but this may well be the key to its success It is understandable that the partners in the new merger should for several years have been obsessed with the need somehow to sell machinery, but it would be a great misfortune if a quite proper concern for the flow of cash were to divert the interests of the new company from the needs of the decades and not just the years ahead Luckily, the order books of the partners to the merger are full though not bursting, so that there should be a breathing space in which the new company can plan a durable strategy for technological development

On the cheerful side, there is at least one respect in which the British company may have an advantage over its competitors elsewhere The link between the British computer companies and the Plessey Company, which is deeply involved in telecommunications as well as computing machinery, may prove to be particularly apt now that it is plain that the next few years are likely to see a blurring of the separation between communications and computers That, the new company may consider, is a stroke of luck

Self-reversing Oceanic Basalts

from a Geophysics Correspondent

THE fact that it has proved possible to construct, using continental igneous rocks, a world-wide geomagnetic polarity time scale for the past four million years implies predominance of field reversal over self-reversal in explanation of the majority of the world's reversely magnetized rocks Furthermore, the recent discovery that the pattern of linear magnetic anomalies adjacent to mid-oceanic ridges correlates with the pattern of normal and reversed periods from the continental scale, not only gives strong support to the ocean floor spreading hypothesis, but also indirectly strengthens the evidence in favour of field reversal The predominance of field reversal and the use of magnetic anomalies as evidence for ocean floor spreading are thus mutually consistent

Despite this consistency, Ozima and Ozima (*Earth and Planet Sci Letters*, **3**, 213, 1967) have now questioned the assumption that the linear ocean anomalies arise from repeated reversals of the Earth's field

They report that three out of eight submarine basalts obtained from Pacific Ocean deep sea mounts exhibit self-reversal properties under certain conditions Saturation magnetization measurements show that each of the three specimens contains in its virgin state, a single magnetic component with a Curie point of 250° C On heating to 400° C, this component is partially converted to a new magnetic phase possessing a Curie point of 300° C Heating to even higher temperatures produces a single phase having a Curie point of 560° C

What is significant, however, is that if one of these specimens is heated to any temperature between 300° C and 330° C for a few minutes, and then re-cooled in the geomagnetic field, the resulting magnetization is antiparallel to the field The reason is that the unconverted part of the primary magnetic phase, of Curie point 250° C, interacts magnetically with the newly produced component of higher Curie point to produce a net reversed moment Below 300° C there is insufficient new material for this to occur, and above 330° C not enough virgin phase remains, but as long as the temperature of the specimen is not maintained at 300° C to 330° C for too long a time, the balance of old to new material is just correct for the interaction to occur Nor is this merely a low magnetic field phenomenon, for fields of up to 2,600 oersteds are insufficient to suppress the self-reversal

One may argue, of course, that the laboratory processes used by the Ozimas to produce self-reversal over a limited temperature range rarely occur in nature supported by the fact that virgin specimens still contained only the low Curie point magnetic phase), and thus that it is unlikely that self-reversal occurred during the production of the natural magnetization Moreover, the correlations between the linear ocean anomalies and the continental polarity time scale, and between each of these and the reversals patterns in deep sea sediments, are too tight to allow the existence of widespread self-reversal in oceanic basalts For these reasons the work of the Ozimas is likely to be of greater interest to those concerned with the phenomenon of self-reversal itself

Carcinogenic Oil Fractions

IN 1948, it was realized that workers who had been exposed for many years to "cutting oils" applied to the cutting edge of machine tools tended to develop skin cancers In the same year the Medical Research Council set up a committee on the carcinogenic action of mineral oils under the chairmanship of Professor T Ferguson The aim was to carry out an intensive examination of crude oils like those used in industry, in order to isolate and identify the carcinogenic constituents It was also hoped that methods might be developed for the removal of these carcinogens and that specifications for safe oils might be formulated Twenty years later the committee's findings have been published by HMSO in No 306 of the council's special report series, price £2

The research was carried out at the universities of Birmingham, Exeter, Glasgow and Leeds, and the University of Manchester Institute of Science and Technology Biological tests were also carried out at the Chester Beatty Research Institute, and quantitative techniques were evolved at the MRC Statistical Research Unit Using three crude oils from fields in Kuwait, Oklahoma and Lagunillas, the research consisted first of the fractionation of the oils by physical and chemical means, and second of the biological testing of fractions produced in this way Rabbits, which were found to be more sensitive to carcinogens in mineral oil than mice, were used in the biological tests

The principal fractionation techniques used were vacuum distillation, solvent extraction, adsorption chromatography and chemical treatment, and care was taken not to produce permanent chemical changes in the oil constituents The first exploratory studies led to the isolation of some 45 pure compounds, some of which had not previously been recognized as constituents of crude, uncracked mineral oils, and none of which is known to be markedly carcinogenic Some of the more complex hydrocarbons isolated from the higher-boiling point fractions were shown to be weakly carcinogenic, and included 4-methyl-1,2-benzanthracene and 7-methyl-1,2-benzanthracene Other isolated substances approach in complexity the known polycyclic aromatic carcinogens and may contribute to the total carcinogenic activity of the oil In the biological tests, oil fractions were either painted on or injected subcutaneously into experimental animals which were later examined for tumours By diluting the fractions to be tested with medicinal liquid paraffin, it was shown convincingly that the carcinogens reside in the aromatic fractions of the oil which can be extracted with acetone or other solvents

Although the general chemical nature of the active ingredients has been established, the committee has unfortunately failed to develop rapid methods of detecting carcinogens in the oils

Effect of Densely Ionizing Radiation

from a Correspondent

MAMMALIAN cells and higher plant cells are more susceptible to damage from densely ionizing radiations, such as α-particles or fast neutrons, than from hard X-rays In more quantitative terms, the relative biological efficiency (RBE) of these radiations compared with hard X-rays is greater than one The most commonly accepted explanation is that a certain minimum amount of energy deposited in a given length of track is necessary for the production of a biological effect In this interpretation the effectiveness of hard X-rays is due to the densely ionized tails of the tracks of recoil electrons, or to chance interaction between tracks when large doses are used Using data on the RBE of deuterons and helium nuclei of various energies on the killing of human kidney cells *in vitro*, Barendsen (*Int J Rad Biol*, **8**, 453, 1964) estimated that a lethal event was produced when more than about 500 eV (15 "ionizations") was deposited in a target of about 100 Å thick

The sensitizing effect of oxygen decreases with increasing "density of ionization", and this effect has been attributed to the same cause Radicals formed close together along a densely ionized track were thought to interact and produce permanent damage which could not be affected by the presence or absence of oxygen

Recently, however, Neary (*Int J Rad. Biol*, **9**, 477, 1965, **11**, 209, 1966, **12**, 317, 1967) has suggested a different mechanism based on observations of chromosome aberrations in *Tradescantia* microspores irradiated with very soft X-rays. Neary's theory is that production of a chromosome aberration results from interaction between two damaged targets, in each of which the damage is produced by a single energy-loss event. The increased effectiveness of densely ionizing radiation is due to the greater chance of interaction between the two damaged targets when they are produced close together by a single particle. Neary also suggests that cellular killing by radiation is due to the same mechanism. This theory gave results agreeing well with the observations when irradiations were made in aerobic conditions. Under anoxic conditions, however, the RBE was found to rise too quickly with increasing density of ionization. This observation could be explained only by invoking a further hypothesis, namely, that oxygen was actually produced in the tracks of densely ionizing radiation, a hypothesis first made explicitly by Shchepotieva, Ardashnikov, Lurje and Rahkmanova (*Izvestia Akademii Nauk USSR*, biological series No. 4, 642, 1961) and suggested by many previous observations that oxygen is produced when pure water is irradiated by α particles but not by X-rays.

Recently, Alper and her colleagues have been able to test this hypothesis experimentally (*Brit. J. Radiol.*, **40**, 843, 1967, and *Radiation Research*, **32**, 780, 1967). The rests were based on irradiation of bacteria with X-rays and fast neutrons, the latter producing recoil protons with fairly dense ionization. The sensitivity of the bacteria was studied as a function of oxygen concentration using both types of radiation. The results fitted the model of oxygen production by densely ionizing radiation and the concentration of oxygen formed in the secondary tracks from fast neutrons was found to be 0.83 μmole per litre. An independent test was also made by comparing the relative sensitivity in the presence and absence of oxygen (OER) of several strains of bacteria irradiated with X-rays and fast neutrons. A theoretical interpretation of the observed relationship between the values of OER with X-rays and neutrons led to a value for the oxygen produced, in the densely ionized tracks, of 0.76 μmole per litre. The agreement with the first model is remarkable considering the experimental uncertainties. This confirmation of the importance of oxygen production in the tracks of densely ionizing particles is a valuable support for Neary's theory.

Cysteamine as a Radioprotector

from our Medical Biochemistry Correspondent

IT is well known that cysteamine (the amine formed by decarboxylation of the amino-acid cysteine) can protect cells against the effects of ionizing radiation, but how it does this is unknown. It has been suggested that the thiol group (SH) of cysteamine may form a mixed disulphide with the SH groups of tissue proteins, thus protecting the protein SH groups from attack by free radicals which are formed by ionizing radiation. One objection to this theory is the uncertainty about the extent to which proteins form mixed disulphides with small molecular weight thiols under physiological conditions. Modig (*Biochem. Pharmacol.*, **17**, 177, 1968) has now shown that normal preparations of proteins do contain mixed disulphides of proteins and small thiols. He has estimated protein and non-protein sulphydryl groups in crystalline bovine serum albumin and in preparations of protein from Ehrlich ascites tumour cells before and after treatment with sodium borohydride to reduce the disulphide bonds. In both preparations there was an increase in both protein and non-protein sulphydryl groups after treatment with sodium borohydride. Usually, three times as much thiol was bound to protein as was bound to other small molecular weight thiols. The author points out that this accounts for discrepancies in earlier estimations of disulphides in proteins because these have sometimes estimated protein disulphides and small disulphides together. 25 per cent of the thiol compounds liberated from the proteins was glutathione, but the other compounds were not characterized.

The protective effect of cysteamine when irradiation is given at different stages of the cell cycle has been studied in tissue cultures of Chinese hamster cells growing synchronously by Sinclair (*Science*, **159**, 442, 1968). Cysteamine reduced the number of cells killed by X-irradiation at all times. The protective effect was greatest, however, in those stages of the cell cycle when the cells are normally very sensitive to radiation, such as the G_1 period just after mitosis, and least in the stages of the cell cycle when the cells are normally more resistant (the end of the synthetic period S). When relatively high concentrations of cysteamine were added, however, the number of cells killed did not depend on the stage of the cell cycle at which irradiation took place.

Using the same experimental material—synchronously dividing Chinese hamster cells in tissue culture—Klevecz and Puddle (*Science*, **159**, 634, 1968) have shown that the activity of lactate dehydrogenase and glucose 6-phosphate dehydrogenase increases intermittently during the cell cycle. The increases occur during G_1 (three hours after mitosis), in the middle of the synthetic period (seven hours after mitosis) and in the late stages of the synthetic period (ten hours after mitosis). The increases correlated with increases in cell size and total protein, suggesting that enzyme synthesis generally varied in this cyclic manner during the cell cycle. This result suggests that cysteamine radioprotection is not due to an effect on protein synthesis, though there may be a difference in the number of proteins with sulphydryl groups synthesized during the sensitive G_1 phase and the resistant S phase.

Cyclic Antibiotics as Cation Carriers

from a correspondent

THE elucidation by Kilbourn *et al.* (*J. Mol. Biol.*, **30**, 559, 1967) of the molecular structure of a crystalline complex formed between potassium ions and nonactin, one of the cyclic antibiotics, may account for many of the curious properties of this substance and, by inference, for other antibiotics of the same type. These antibiotics (the cyclic polypeptide valinomycin and the gramicidins are more familiar examples) act by allowing potassium ions, protons and other cations but generally not sodium ions, to move across cell membranes and, in particular, across the mitochondrial membrane (Pressman *et al.*, *Proc. US Nat. Acad. Sci.*, **58**, 1949, 1967).

A significant feature of their chemical structure is the preponderance of hydrophobic side chains and the absence of free amino, carboxyl and hydroxyl groupings, which are associated with a high lipid solubility The crystal structure analysis of K^+—nonactin reveals that the K^+ ion is in the centre of the molecule, bonded to 8 oxygen atoms of keto and furane groups This structure is surrounded by the hydrophobic side chains, with the methyl substituents and the methylene group of the furane rings on the outside This structure is quite the reverse of the structure found for globular proteins—which have a hydrophobic centre surrounded by hydrophilic residues—but it is eminently favourable for a molecule which becomes embedded within the lipid side chains of the cell membrane Furthermore the structure of the antibiotics suggests that they act by enabling cations to dissolve in the hydrocarbons and hence cross the membrane In other words, they probably kill bacteria by making them leaky The antibiotic is thus a model for the membrane "carriers", which have been proposed many times over the last thirty years Pressman *et al* specifically put forward this view and called the antibiotics *ionophores* The discrimination between potassium and sodium ions (approaching 10,000 to 1 in certain cases) may depend on the size of the hydrated ion but at least in the case of nonactin the central site can accommodate both K^+ and Na^+

It is encouraging for students of cell membranes to find materials of biological origin, yet of simple structure, which possess such cation selectivity Interestingly as Andreoli *et al* hav shown (*J Gen Physiol*, **50**, 2527, 1967), valinomycin can confer cation selectivity on artificial lipid bilayers which are non-selective in the absence of the antibiotic It can also increase markedly the potassium permeability of the sheep erythrocyte membrane (*ibid*, p 2513) What is even more exciting, Mueller and Rudin (*Nature*, **217**, 713, 1968) have just shown that the antibiotic alamethicin induces action potentials in an artificial bilayer membrane which also contains basic protein How likely is it that transport across cell membranes is normally mediated by similar small molecules ? Pressman *et al* point out that many of these antibiotics contain D-amino acids, which are rare in most organisms, and replacement of the D-residues with the L-isomer severely reduces the antibiotics ability to transport K^- ions Alamethicin, although devoid of D-amino acids, contains 8 residues of the rare amino acid methylalanine Will it be possible to find, or synthesize, a polypeptide carrier from the common amino acids ? And can such a carrier, if it is found, complex with and solubilize sugars, the other major class of substances for which membrane carriers have been proposed ?

Factors for Protein Synthesis

from our Cell Biology Correspondent

The number of factors required for protein synthesis is increasing steadily Two initiation factors are required for the binding of N-formyl-methionine *t*RNA at chain initiation, at least two supernatant factors appear to be involved in the GTP dependent binding of aminoacyl-*t*RNA to ribosomes during chain elongation and now, according to Brown and Doty (*Biochem Biophys Res Comm*, **30**, 284, 1968), there is a specific protein factor—factor 3—which stimulates the binding of *m*RNA to ribosomes

The first clue to the existence of factor 3 was when Brown and Doty found that the binding of synthetic *m*RNAs and *R*17 viral RNA to ribosomes decreased after the ribosomes were washed in 1M NH_4 Cl They inferred from this that a specific messenger binding factor was being washed off the ribosomes and so they set out to purify it Briefly, the purification involved precipitating ribosome washings at 40–60 per cent saturation with ammonium sulphate, followed by column chromatography, on TEAE cellulose, of the redissolved precipitate The fractions from the column were assayed by incubation with ribosomes in the presence of Mg^{++} ions and either the synthetic *m*RNA ApUpG(pA)$_{40}$ or *R*17 RNA As expected, some of the fractions stimulated, 2–4 fold, the binding of *m*RNA to ribosomes Further purification of these fractions yielded the purified factor, which has an ultra-violet spectrum characteristic of protein and not nucleic acid and which migrates as a single component on polyacrylamide gel electrophoresis at *p*H 8 6

Is factor 3 the same as either of the initiation factors—F_1 and F_2—discovered by Stanley and Wahba *et al.* (1966) ? Factors 3 and F_1 behave very differently during column chromatography so they are unlikely to be the same To check that factor 3 differs from F_2, Brown and Doty did an experiment to see if factor 3 could substitute for F_2 during the initiation of translation in a cell-free system programmed with the synthetic messenger ApUpG(pU)$_{30}$ Factor 3 could neither substitute for F_2 in the presence of F_1 nor for F_1 in the presence of F_2 It must therefore be a new and distinct factor, although the experiments do not show whether or not factor 3 is required for translation of *m*RNA as well as binding of *m*RNA to ribosomes

Factor 3 is, however, probably identical to part of an activity which has apparently been discovered by Revel *et al* (in the press, 1968) and is called factor *C* (unfortunately, until all the various factors involved in protein synthesis have been fully characterized, there is bound to be confusion of nomenclature and equivalence) Apparently factor *C*, which was isolated from ribosome washings, is required for the attachment of ribosomes to nascent T_4 *m*RNA In the absence of factor *C*, ribosomes do not stimulate the rate or amount of *m*RNA synthesized by RNA polymease with DNA as template Brown and Doty tested factor 3 for this activity and, in the presence of ribosomes, factor 3 gives about a fivefold stimulation of transcription

F_1 and F_2 and GTP stimulate the binding of F-met-*t*RNA$_F$ to the 30S ribosomal sub-unit in the presence of the AUG code This results in formation of an initiation complex According to Mukundan *et al* (*Nature*, **217**, 1013 1968), F-met-*t*RNA$_F$ binds initially to the amino-acyl binding site and not the peptidyl site on the 30S sub-unit, this is the same site that is used for decoding all the other amino-acids

The binding of all the other amino-acyl *t*RNAs during chain elongation is mediated by GTP and a supernatant factor *T*, which can be separated into two components *Tu* and *Ts* Lucas, Lenard and Haenni (*Proc US Nat Acad Sci*, **59**, 554, 1968) have confirmed that this binding is dependent on factor *T* and GTP and have shown that *T*, GTP and the amino-acyl *t*RNA form a complex This complex will only bind to 70S ribosomes, so both sub-units are necessary and peptide bond formation is a consequence of the binding However, yet another factor, *G*, is required for polymerization to go beyond the depeptide stage Factor *G* presumably promotes the movement of the peptidyl-

P-L Biochemicals is a basic producer of polynucleotides. We make all of the polymers listed and every nucleoside diphosphate that goes into them. We even produce our own polynucleotide phosphorylase enzyme All of this gives us more control in the production of polynucleotides and assures you of a high quality product. But we don't stop there. Each product batch is carefully analyzed and a complete report accompanies each shipment

Polynucleotide Phosphorylase for "do it yourselfers." Our new Research Enzyme Group is proud to offer polynucleotide phosphorylase (Cat. No 0302) for basic research and for polynucleotide "do it yourselfers" It is modestly priced at 100 mg /$30.00; 1 gram/ $200.00 This is the same enzyme we use ourselves and it is guaranteed suitable for polynucleotide synthesis We are also working toward a purified primer dependent enzyme and invite your inquiries.

Complete information will be found in our new Catalog No. 101—free on request.

Does Energy Data Interest You?

Nearly every operation in industry and in research involves an energy change How many of the tasks in your field have to do with a change in heat?

A change that may mean you want to measure Heat of Solution, Heat of Adsorption, Heat of Reaction, Heat of Combustion, Heat of Vaporization, Heat of Dilution, Heat of Mixing, Specific Heat of Solutions and so on Did you know that you could carry out all these measurements with ONE instrument You can, with

The LKB Precision Calorimetry System LKB 8700

The most versatile instrument available for calorimetric measurement today Our research team have incorporated in one system the following calorimeters

General Purpose and Solution Titration Heat of Vaporization Closed-Bomb Reaction • An adiabatic control unit for the study of slow reactions • Rotating Bomb for Heat of Combustion

Whatever your interest in chemical and physical research, Government, University, Industry, Space Research, National Defence, whatever your end-product, chemicals, oil, rubber, telephones or motor cars, pharmaceuticals or scientific instruments, somewhere along the line you will find you need the LKB Precision Calorimetry System to provide you with accurate thermochemical data

Write today for full information on this instrument that brings you instantly a complete range of calorimeters, just plug in and choose which one will meet the requirements of the energy change you want to measure

*t*RNA from the amino-acyl site to the peptidyl site in the 70S ribosome.

Yet More Haemoglobin

from our Molecular Biology Correspondent

THE important concept that the sigmoidal oxygen-dissociation curve of haemoglobin is a consequence of sub-unit exchange, and that the symmetrical dimer $\alpha\beta$ is thus to be regarded as the basic functional entity, is by now well established. An interesting demonstration of this mechanism is provided by some experiments of Enoki and Tomita (*J. Mol. Biol.*, **32**, 121, 1968), who prepared hybrid molecules of human and canine haemoglobins, $\alpha_2^{CAN}\beta_2^{A}$ and $\alpha_2^{A}\beta_2^{CAN}$, in which either the human or the canine chains were in the cyanmet-form, and therefore non-functional. There are four such species, and all were found to show no haem–haem interactions whatever (Hill constant, *n*, of unity). By contrast, a haemoglobin, such as $\alpha_2^{A}\beta_2^{A}$, in which half the haem groups have been oxidized to the ferric state, still shows well-developed haem–haem interactions ($n=1.9$), because functional sub-units of both kinds are present. These persuasive results seem to leave little room for doubt that sigmoidal oxygen binding requires two types of functional sub-unit. In other respects, the interaction between α and β sub-units persists in the hybrid species, in particular the Bohr effect is not destroyed, whereas in species possessing only one type of sub-unit (β_4^{A} for example) the Bohr effect is absent.

Another example of the structural interdependence of sub-units in the absence of haem–haem interactions occurs in the haemoglobin-M species—human variants, in which the iron-bound histidine in one or the other type of sub-unit is replaced by tyrosine. Epstein and Stryer (*ibid.*, 113) have measured the kinetics of binding of azide ions by two methaemoglobin-M variants, one with the mutation in the α-chain, the other in the β-chain: the abnormally linked haems are incapable of binding ligands. The α-chain variant reacts much more rapidly than normal methaemoglobin, and at the same rate as metmyoglobin, whereas the β-chain variant reacts at the same rate as the normal species. Thus the reactivity of a normal β-chain is modified by association with an aberrant α-chain. Also, equivalent modifications in the α- and β-chains have non-equivalent effects on the partnering chains. It is worth pointing out that the α-chain haemoglobin-M variant has no Bohr effect, and these sub-units are thus defective in the way they interact with their partners.

The most important development in haemoglobin chemistry in the recent past has been the discovery by the Benesches of a co-factor, diphosphoglycerate, which profoundly influences the oxygen-binding behaviour and controls the function of haemoglobin *in vivo*. The manner of its interaction is the subject of a further study (*Proc. US Nat. Acad. Sci.*, **59**, 526, 1968). The results are remarkably clear-cut, in the first place, haemoglobin stripped of the co-factor retains its sigmoid oxygen-uptake curve. Addition of the co-factor then leads to a huge displacement of the curve in the direction of lower affinity. The shift is essentially complete when one mole of diphosphoglycerate has been added for each mole of haemoglobin tetramer. Moreover, direct binding experiments show that deoxygenated haemoglobin binds exactly one mole of the co-factor per mole of tetramer, whereas oxyhaemoglobin binds none at all. The change of oxygen affinity with concentration of diphosphoglycerate is then a reflexion of this difference. The stoichiometry of the interaction is altogether at odds with the requirements postulated in the original formulation of the allosteric hypothesis; the hypothesis therefore already stands in need of revision if it is to retain any generality.

Intellectual Style and High School Science

by

A. J. CROPLEY

T. W. FIELD

University of New England,
Armidale, NSW, Australia

Tests on Australian schoolchildren have revealed a relationship between intellectual style and specialization in science similar to that found in British schools. Convergers, who excel in close logical reasoning and do well in intelligence tests, show a bias for science. Divergers, who have high IQs but show low scores in tests consisting of questions with no one correct answer, tend to avoid science in schools.

HUDSON[1] has shown that British grammar school boys specializing in science are usually convergent in intellectual bias. But, despite the existence of what is now a well established relationship in the case of British schoolboys, Cropley has reported that outstanding Australian undergraduate scientists were mainly divergers[2]. Thus the two sets of findings look to be contradictory. We report here additional Australian data involving, not undergraduates, but schoolchildren, so that a more direct comparison can be made with Hudson's findings. The main point at issue is whether intellectual bias and science specialization are differently related in Australia than in Britain, or whether the Hudson finding prevails when Australian high school children are studied, and is reversed only at university level.

A battery of tests including a divergent thinking test (tin can uses[3]), and a convergent thinking test (the AL–AQ tests of intelligence[4]) was administered to 218 students in the final 2 years of study at two large rural high schools in New South Wales. The 218 students included 106 girls, who had a mean age of 16 years 10 months (range 15 years 8 months to 18 years 2 months), and 112 boys for whom the mean age was 17 years 1 month (range 15 years 8 months to 18 years 7 months). In that the group of students studied included girls as well as boys, the data reported here differ from the studies previously mentioned. The inclusion of girls, however, permits comparisons between the intellectual styles of the two sexes, and so extends earlier work. For this reason, the data gained by scoring the girls' test protocols were included in this report. In the New South Wales educational system, students at fifth and sixth form level may study science at any one of four possible levels, including "first level", "second level (full)", "second level (short)", or "third level". They may also elect not to study sciences at all, joining "non-science" groups. For the purposes of this article, students who had elected either first level or second level (full) were regarded as science specialists, while all students selecting other levels or non-science were regarded as non-specialists. The rationale for treating the first two levels as indicating science specialization rests in the provisions of the so-called "Wyndham scheme" (published by the Australian Council for Educational Research (ACER), and specifically designed for use with above-average groups) of which the organization of science teaching in New South Wales is a result.

The divergent thinking test was scored for originality according to the procedures described by Torrance[3], using the weights suggested by Cropley[5]. The convergent tests were scored according to the published specifications. Subsequently, raw scores on both intellectual tests were transformed into normalized standard scores to eliminate problems associated[4] with differing means and standard deviations. Finally, a bias score was obtained for each student by subtracting the convergent score from the divergent score, according to procedures described before[2]. Each student's rating as either a science specialist or a non-specialist was known, and so it was possible to look at the relationship between science specialization on the one hand, and intellectual bias on the other.

A clear-cut, preliminary finding was that there was a strong relationship between sex and bias. Although the full group of 218 boys and girls contained nearly equal numbers of divergers and convergers (115 divergers, 103 convergers), among the 112 boys, no fewer than seventy-two were divergently biased, forty convergently. The 106 girls, by contrast, included only forty-three divergers, while sixty-three were convergently biased. This relationship was highly significant ($\chi^2 = 10\cdot75$, degrees of freedom $= 1$; $P < 0\cdot01$), and indicated a marked tendency for boys to be divergers, within the context of a group of both sexes. This finding is consistent with data based on Canadian schoolchildren reported elsewhere[6]. In that study a group of students rated as "highly original" consisted mainly of boys, a group rated "unoriginal" mainly of girls.

In view of the large sex differences in bias, the relationship of course preference to bias was examined separately for boys and for girls. The 112 boys included thirty-six science specialists, of whom eighteen were divergers, eighteen convergers, and seventy-six non-specialists, of whom fifty-four were divergers and twenty-two convergers. This distribution of divergence/convergence among science specialists and non-specialists differed significantly from what would be expected by chance ($\chi^2 = 4\cdot71$, degrees of freedom $= 1$, $P < 0\cdot05$). There was a disproportionately large number of convergers among the science specialists. Among the girls, the distribution of divergers and convergers was almost exactly what would have been expected by chance ($\chi^2 = 0\cdot00$). Thus the data show that specialization in science among the boys was related to the convergent bias, a finding supported by a correlation of no less than $0\cdot485$ ($P < 0\cdot01$, degrees of freedom $= 110$) between degree of convergence and level of science achievement. Even among the girls the figure was $0\cdot347$ ($P < 0\cdot01$, degrees of freedom $= 104$).

In demonstrating the existence of a significant relationship between specialization in high school science and convergent intellectual bias, these data suggest that the state of affairs shown to exist among British schoolboy science specialists[1] may well hold for Australian boys too. Taken in conjunction with Cropley's earlier report[2] that, at university level, outstanding undergraduate scientists were not convergers as is the case with schoolboys, but divergers, the data contain an interesting implication. Apparently, although disproportionately large numbers of science specialists entering university are convergers, even as early as at senior undergraduate level, the most outstanding young men come mainly from among the relatively few divergers. This formulation is consistent with Gibson and Light's[7] failure conclusively to separate Cambridge scientists from the general populace, on the basis merely of IQ. It may well be that outstanding scientists are distinguished by the unusual bias of their intellects (unusual among science specialists, that is), rather than by unusual levels of ability.

Discontinuities in the History of Sea-floor Spreading

by

ERIC D. SCHNEIDER
PETER R. VOGT
US Naval Oceanographic Office,
Washington, DC

There seems to have been a lapse in the crustal spreading of the sea floor from the Mid-Atlantic Ridge during the late Tertiary period.

GEOLOGICAL and geophysical data obtained from the sea floor in the past decade have led to the hypothesis that the crest of the mid-ocean ridge is a place of injection of new crust into the ocean floor and that the sea floor is as a result spreading away from the crest[1-3]. These ideas have proved fertile for the explanation of the pattern of marine magnetic anomalies suggested by Vine and Matthews[4]. Using this hypothesis workers such as Pitman and Heirtzler[5] have recently given strong support to the idea that the ridge is truly spreading away from its crest at rates of 1 to 5 cm a year.

As new dikes are injected at the ridge axis, they acquire the magnetization of the geomagnetic field at the time they cool through the Curie temperature. The Earth's field has been shown to have reversed its polarity approximately once every few hundred thousand to a million years during late Tertiary and Quaternary time[6]. The oceanic crust has therefore acquired strips of alternately polarized crust which give rise to a remarkable system of linear positive and negative magnetic anomalies which parallel, and are symmetrical about the ridge crest where they were created.

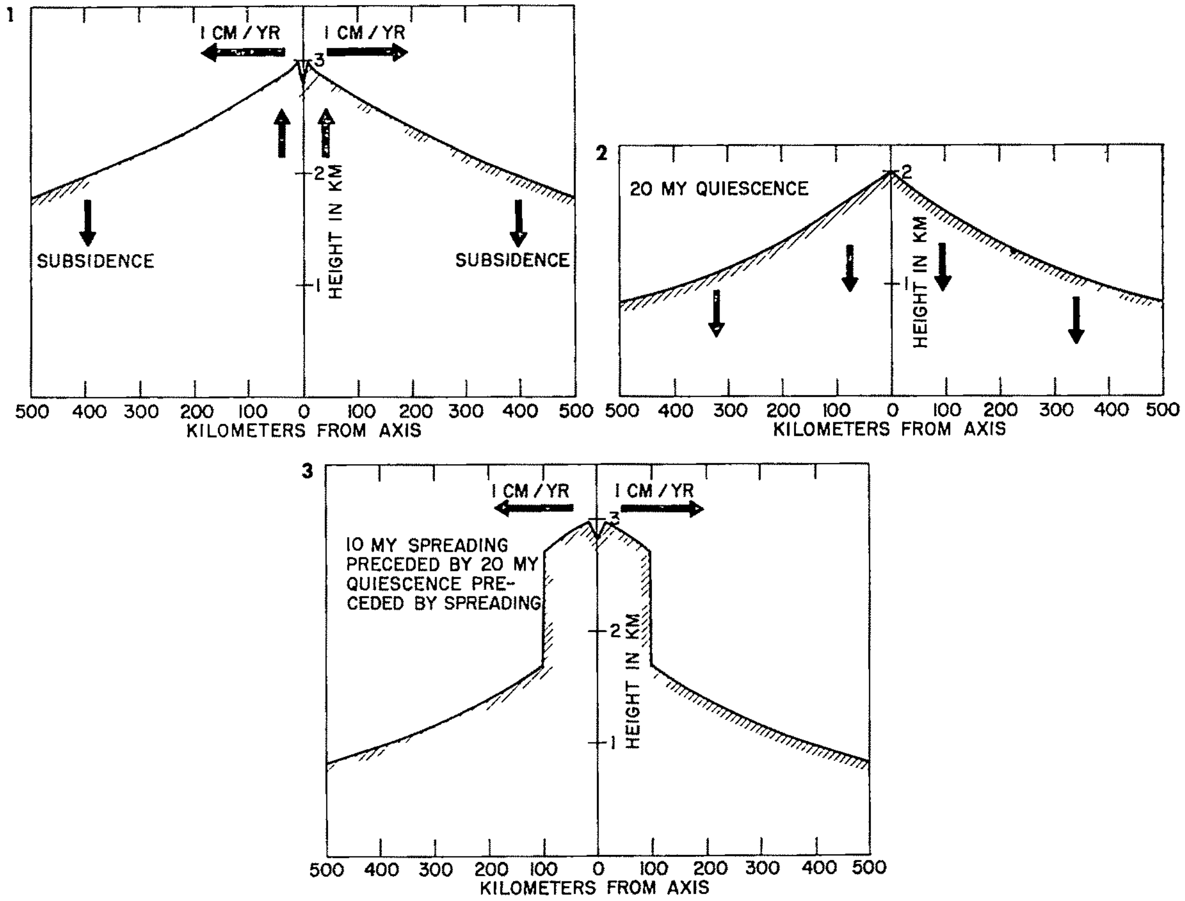

Fig. 1. Hypothetical evolution of a ridge profile during steady-state spreading (1), at the end of a 20 million year lapse (2); and 10 million years after renewal of spreading (3). The profiles were constructed from a steady-state thermal expansion model[11], corrected for isostatic compensation. It was assumed that subsidence depends only on the time after extrusion.

Ewing and Ewing[7] have recently proposed that there was a lapse in crustal spreading which lasted from between 40 or 50 and 10 million years before the present (mybp). As evidence they offer smoothed sediment thickness profiles across mid-ocean ridges. The records of seismic profiles show a relatively abrupt increase in the thickness of unconsolidated sediments at a distance X from the axis of mid-ocean ridges, where X is approximately 100 km on the Mid-Atlantic Ridge and 400 km on the East Pacific Rise. Recent spreading rates seem to have been 1–2 cm/yr and 3–5 cm/yr on the two ridges, respectively[5]. If sedimentation rates have been relatively uniform throughout the Cenozoic, the abrupt thickening of sediment suggests a period of quiescence, or a lapse in crustal spreading.

We shall first examine an idealized steady-state model of ridge spreading and then set out in a generalized fashion the various geological or geophysical criteria by which a lapse in sea-floor spreading might be recognized.

By a lapse in spreading we mean the following. Let X be the distance, measured parallel to the spreading direction, of a parcel of crust from the axis of the mid-ocean ridge. Then a lapse is recorded by two strips of crust, $X_1 < X < X_2$, which were generated at a slower rate when compared with spreading rates S_1 and S_2, before and after the lapse. These strips of crust may be very narrow if spreading stopped and started relatively abruptly. The difference in appearance of the crust $X < X_1$ and that of the crust $X > X_2$ will in general depend on (*a*) the length of the hiatus, (*b*) the difference in spreading rates, S_1–S_2, and (*c*) the time that has elapsed since the end of the hiatus.

On discussion of possible criteria for recognizing a hiatus, several of these criteria, including new magnetic, topographic and seismic profiler data, are then offered as additional support for the hypothesis of Ewing and Ewing[7] that there was probably a middle or late Tertiary lull in crustal spreading, at least on the Mid-Atlantic Ridge. The possibility of other discontinuities in spreading rate is then considered.

The Steady-state Model

Before discussing possible irregularities in the history of crustal spreading, we shall first discuss the possibility and problems involved in an ideal steady-state mid-ocean ridge. This model requires in general that mantle derivatives are injected at a constant rate at any point on the ridge. There may be some injection at a distance X from the axis, causing an increase of spreading rate away from the axis. In a steady-state model, however, any "geophysical operator" G_t which changes the crust at X does not, on the average, change with time The remarkable symmetry of magnetic and topographic profiles across active ridges (which may not be steady-state) suggests that bilateral symmetry is a basic property of ridges[8] Thus $G_t(X) = G_t(-X)$ It seems to be an additional characteristic of ridges that, apart from occasional volcanoes, the upper crust (above the region of possible phase changes) is not appreciably modified after leaving the axial region For example, the work of Sykes[9] has shown that epicentres on the Mid-Atlantic Ridge usually fall between ± 10 km of the axis, suggesting that at present most tectonic activity on the ridge takes place at the crests. Furthermore, the geomagnetic history, when compared with the magnetic anomaly signature, suggests that the spreading rate does not increase appreciably away from the axis[5] Matthews and Bath[10] have shown that the departure of observed magnetic profiles across the Mid-Atlantic Ridge from the classical Vine–Matthews theory is best accounted for if it is assumed that new dikes do not necessarily bisect their predecessors but have a normal distribution about the axis with $\sigma = 5$ km It therefore appears that in the upper crustal layers $G(X) \approx 0$ for $X \gg 5$ km except for occasional vulcanism and the effects of sedimentation

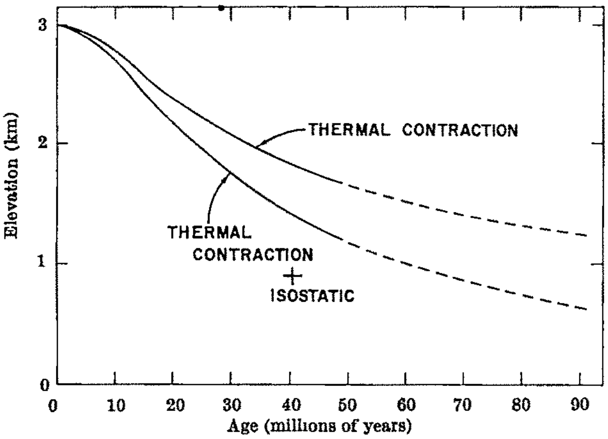

Fig 2 Subsidence against time for a parcel of crust riding down the flanks of a steady-state ridge Solid curve, estimated from ref 12, represents pure thermal contraction Dashed curve includes additional subsidence if increase of water column and thermal contraction of water column is compensated with material of density 3 2

One obvious consequence of a steady-state ridge is that the spreading rate $S(X)$, the subsidence rate $f(X)$ and the regional topographic slope $\theta(X)$ are related by $\tan\,\theta(X) = f(X)/S(X)$. A bathymetric-magnetic profile may yield the slope and spreading rate, allowing the calculation of the subsidence rate Vogt and Ostenso[11] have observed that, if the Pacific–Antarctic Ridge ($S = 4\ 5$ cm/yr) and the Reykjanes Ridge ($S = 1$ cm/yr) are steady-state, f is about 10 cm/1,000 yr for the first $12–15 \times 10^6$ yr after extrusion at the axis. The same quantity $f(X)$ drops to a few cm/1,000 yr on the lower flanks, provided, of course, that the spreading rate has been constant in time The subsidence rates of guyots and the edge of the eastern United States continental shelf have been of the same order of magnitude

A recent attempt at computing a model steady-state mid-ocean ridge[12] based on the assumption that ridge uplift is due entirely to thermal expansion predicts a maximum subsidence rate of 2 or 3 cm/1,000 yr for the first 50 million years. According to this model of Langseth *et al* [12], hot mantle material (1,500° C) is injected at the base of a layer 100 km thick. The material rises to the surface and spreads away from the axis at a constant rate, losing heat by conduction As the hot material spreads away from the axis it contracts In the model computations, the coefficient of thermal expansion, presumably constant, was not specified The conductivity was taken to be constant and equal to 6 c g s throughout the layer. The heat capacity was 0 3 calories/g and the density 3 4 g/cm^3 The thermal equation was solved by iteration for points 10 km apart in the spreading layer The temperature evolution was computed for every point at intervals of 10^5 years, beginning with the equilibrium state in the absence of convection The theoretical mid-ocean ridge models[12] suggest that as long as convection speeds exceed a certain value (0 5 cm/yr), the maximum elevation of the ridges, as well as the rate of subsidence down their flanks is independent of their spreading rate Past variations in the spreading rate may then be reflected by variations in regional slope, because the sinking rate f depends only on the time after extrusion at the axis if $S > 0\ 5$ cm/yr If $S < 0\ 5$ cm/yr, including the limiting case of total quiescence, Langseth's calculations do not yield an exact estimate of f It is, however, clear that, for very slow spreading, the upwelling material loses heat before reaching the surface The crustal elevation of ridges will therefore decline to zero as $S > 0$ Subsidence rates on the flanks of such slow spreading ridges depend on the thermal gradient and therefore also decline when S decreases below 0 5 cm/yr.

There are several significant differences between the Langseth steady-state model and actual ridges These differences, which may be related, are the following

A. Differences between observed and calculated regional topographic slopes—that is, subsidence rates.

B Differences between observed and calculated total uplift

C. Differences between observed and calculated heat-flow anomalies

A. The previous discussion, following from that of Langseth *et al* [12], has assumed that a mid-ocean ridge is the effect of pure thermal expansion, which implies that the mass per unit area below the sea floor remains everywhere constant. But the water column above a parcel of crust increases from 2 or 3 km to more than 5 km as the

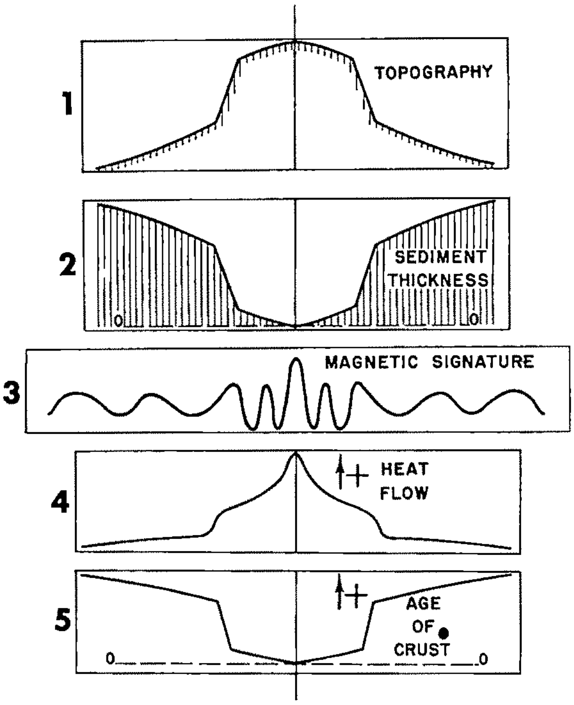

Fig 3 Schematic illustration of several types of evidence for recognizing a lapse in sea floor spreading Relatively abrupt changes in topography, sediment thickness, heat flow and age of crust mark position of lapse Change in magnetic signature could indicate (1) abrupt change in spreading rate, (2) abrupt change in geomagnetic polarity reversal rate, (3) lapse in spreading superimposed on a gradually changing reversal rate, or (4) a combination of (1) and/or (2) with a lapse

parcel moves down the "subsiding conveyor belt" from the crest of the ridge to abyssal depths. This increases the total mass in the crustal column. Talwani *et al* [13] and others have shown, however, that free-air gravity anomalies are nearly zero over the ridge or are, if anything, slightly positive over the crest. The increasing load of the water column above the thermally contracting crust is, therefore, being compensated isostatically. A given thermal subsidence Δh will then be changed because the density and thickness of the crust and the overburden of water is changed. Consider two adjacent crustal columns of identical mass, the one shortened by Δh on account of thermal contraction. Both columns have their tops below sea level and are suspended in a substratum of density ρc. Let the density of water be ρo. Then the difference in water depths to the tops of the two columns is $\{\rho c/(\rho c-\rho o)\}\ \Delta h$, by straightforward application of Archimedes' principle. If $\rho o = 1.03$ and ρc is between 2.8 and 3.4 g/cc, the total subsidence will be between 1.58 Δh and 1.44 Δh. In Fig. 2, an isostatic subsidence curve has been constructed from Langseth's model, taking $\rho c = 3.1$ g/cc. The maximum subsidence rates are about 3.5 cm/1,000 yr after this isostatic correction has been applied to the Langseth model.

The predicted subsidence rates and those "observed" on active ridges (provided the ridges are steady-state) are of the same magnitude. The 10 cm/1,000 yr subsidence rate "observed" for the first 12–15 × 10^6 yr after extrusion is, however, several times that predicted by the Langseth model[12], even after isostatic corrections have been applied. Phase changes under the cooling flanks of this ridge must also contribute to the "observed" subsidence.

B. The Langseth model predicts a maximum elevation of about 2 km for ridges. This seems approximately correct, but may be as much as 50 per cent too small if the equilibrium level of the sea floor is represented by the igneous basement under abyssal plains at large distances from the ridge crest[14]. This discrepancy, if real, might be taken to indicate that the coefficient of expansion is higher, or that phase changes make a significant contribution to the total uplift[3]. If 1 km of the maximum elevation of mid-ocean ridges above the equilibrium level is due to the presence of abnormal mantle with a density 3.25 g/cc, and if this material is being steadily converted to normal mantle of density 3.40 g/cc, the total thickness of anomalous mantle would be 20 km under mid-ocean ridges. The densities are those used by Talwani *et al* [13] in computed crustal models of mid-ocean ridges. The expansion due to phase changes can be no greater than the total, so that the thickness of abnormal mantle converted to normal mantle must be less than 60 km. These figures are very sensitive to the densities of the two phases, which are themselves uncertain. At this stage one can only guess at the phase changes which might be significant in contributing to the subsidence of the flanks of mid-ocean ridges. Three such processes, all of which cause an increase in bulk density, are deserpentization[3], the transformation of basalt to eclogite[15] and the downward freezing of an interstitial liquid basalt fraction in an ultrabasic crystal mush. The last process requires high temperatures and is therefore confined to the mantle except in the region of axial intrusion.

C. The predicted heat flow profile across mid-ocean ridges is broad, high and sharply peaked at the axis, but the active ridges are characterized by relatively narrow belts of rapid heat flow flanked by regions in which heat flow is within 20 per cent of the oceanic average[12]. The high values are found within about 300 km of the crest of the East Pacific Rise and within 100 km of the crest of the Mid-Atlantic Ridge.

Is there any way to adapt the steady-state model to make it fit observational data? The high nearly axial subsidence rate could be due primarily to a phase transformation. Thus, 10 cm/1,000 yr is equivalent to the annual conversion of a layer of density 3.25 g/cc and 2.3 mm thick to the higher density of 3.4 g/cc. This does not account for the discrepancy between observed and predicted heat flow.

The narrow belt of observed high heat flow may suggest that the zone of input is much narrower than assumed in the models[12]. This inference is supported by the existence of a broad magnetic low over the axis of the Mid-Atlantic Ridge. Heirtzler and LePichon[16] ascribed the anomaly to a rise in the Curie isotherm, and their model implies that the Curie isotherm has roughly the shape of an upward pointing wedge with a base 160 km wide at a depth of 30 km, and with its apex about 11 km below sea-level. The melting curve of basalt must form a still narrower wedge, which would then represent the zone of input.

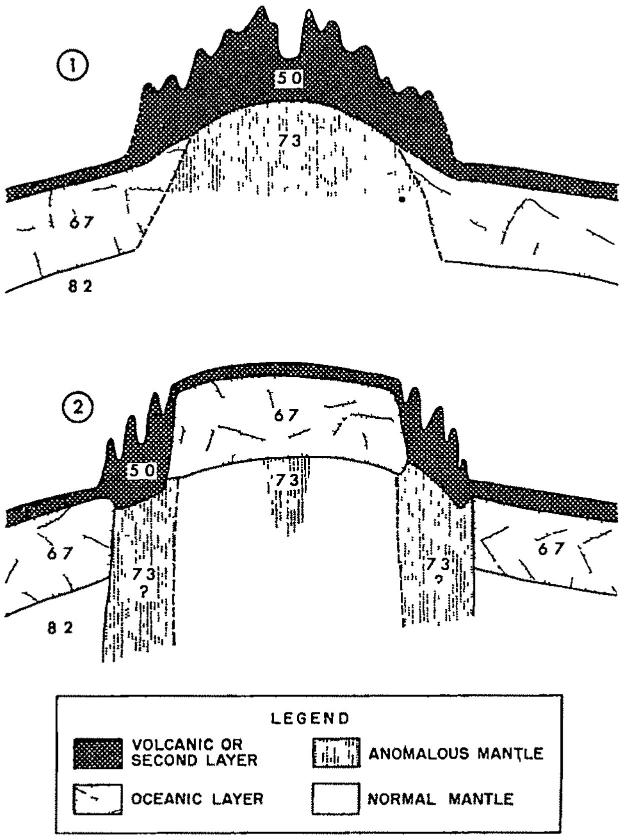

Fig. 4. Crustal structures for two hypothetical spreading histories. In (1) spreading rates were less than about 2 cm/yr before and after the lapse. In (2) the rates exceeded 2 cm/yr except during a period of slower spreading, when crust similar to (1) was generated. Apparently the late Tertiary lapse discussed in the text has been recorded by the Mid-Atlantic Ridge (1) and East Pacific Rise (2) in this manner.

The thermal models of Langseth *et al* [12], on the other hand, predict a broader higher warp in the Curie point surface. The dimensions of this wedge have been interpolated from their Fig. 17, which shows the isotherms due to steady-state spreading at 1 cm/yr. The top of the wedge reaches within about 7 km of the surface and has a base more than 1,000 km wide at a depth of 30 km. Uncertain though the magnetized model calculations may be, it is nevertheless interesting that the width of the zone of input may be only a fraction (1/7 in the rough calculation) of that assumed in the thermal model.

The Curie isotherm also reaches closer to the surface in the thermal models than in the magnetic model. This is consistent with the result[12] that the actual amplitude of the heat flow anomaly is less than that predicted by the thermal model.

The models of Langseth assume constant conductivity

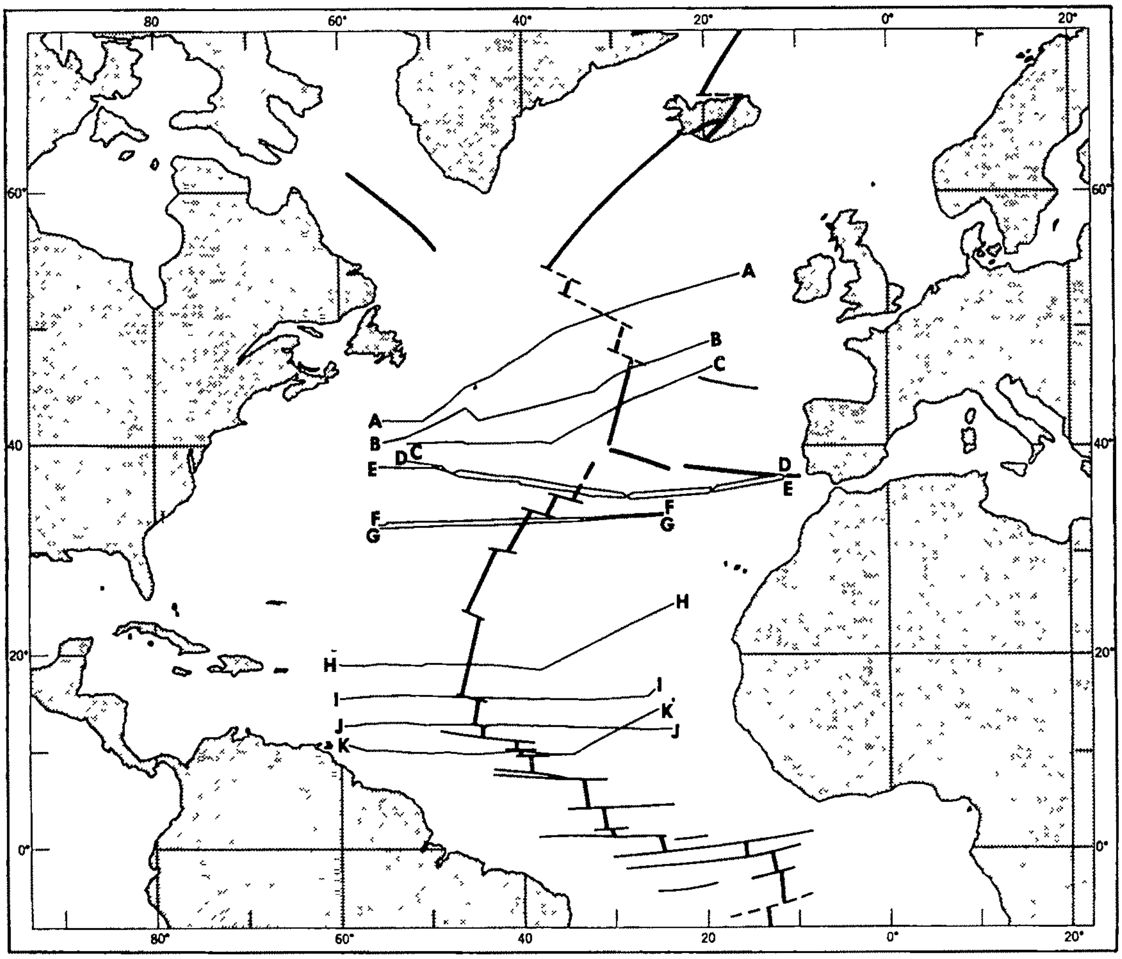

Fig 5 Mid-Atlantic Ridge crest and fracture zones. Superimposed are locations of profiles recording bathymetry, sub-bottom and magnetics Profiles *C*, *D*, *E*, *F*, *G*, *I* and *J* are exhibited in the following figures

It is, however, conceivable that the material under the axis has a much greater effective conductivity at depth, and that the crust has a lower conductivity. The qualitative implication of such a model would be a narrow band of high heat flow in the axial region superimposed on a very flat anomaly extending to the margins of the ocean basins. The latter anomaly must be within 20 per cent of the oceanic average[12]. The high "effective conductivity" in the axial region may simply be a consequence of an effective heat transfer mechanism, as would be provided by the constant injection of new dikes and the emission of lavas

Finally, the possibility must be considered that ridges may be steady-state over periods of 10 to 50 $\times 10^6$ yr but that volcanic cycles of much shorter periods—say 0 1 to 1 $\times 10^6$ yr—may be superimposed on them. Crustal spreading could still be constant while the surface discharge of lavas varied Outbursts of vulcanism may discharge large quantities of heat over short periods of time If the present time is characterized by less than average volcanic and/or plutonic activity, the discrepancy between the model and the observed heat-flow profiles would be understandable Because some active volcanoes occur many hundreds of kilometres from the axis of active ridges, discharges are not confined to the axis Iceland is not typical of the Mid-Atlantic Ridge, but it may be significant that the width of even the very young (0 005 $\times 10^6$ yr) post-glacial volcanic belt on Iceland exceeds the width of the crustal strip generated in 1 $\times 10^6$ yr at 1 cm/yr. The Pleistocene volcanics occur in a complex belt that widens from 100 km in the north to 300 km or more in the south[17]. The actual widening of the crust seems to be 1 cm/yr away from the axis both north and south of Iceland[5,18], implying a widening of only 20 km there during the Quaternary. Svalbard (Spitsbergen) affords similar evidence of exceptional activity during the Quaternary. At distances of 100 to 200 km from the mid-oceanic rift, the continental crust of Spitsbergen has been disturbed by limited Quaternary vulcanism There is no evidence for previous vulcanism since middle Tertiary times[19]

Although it is hazardous to suppose that Pleistocene volcanics occur over such a broad belt on the typical parts of the ridge, the width of the belt of thin sediment (200 km) is about the same as the Pleistocene volcanic zone on Iceland. The possibility cannot be ruled out that the zone of thin sediments on the axis of the Mid-Atlantic Ridge was created when Pleistocene and later volcanic activity obliterated much of the earlier sediments. This would invalidate the interpretation by Ewing and Ewing of the change in sediment thickness as a marked age difference between adjoining parts of the ridge It should be emphasized that such episodic vulcanism is not necessarily inconsistent with a constant spreading rate, although a thickening of the volcanic layer could be expected. Magnetic surveys of Iceland itself will decide whether the island is at all typical with respect to magnetic anomalies and sea floor spreading. There seem to have been several rifts which have been intermittently active on Iceland[17], and this could partly account for the broad Pleistocene volcanic belt.

Although it is conceivable that steady-state models can be found which account for the present observations, particularly if vulcanism is not confined to the central rift or/and is episodic in nature over a short period of time, several difficulties in the steady-state model disappear if crustal spreading does not always proceed at a constant rate.

Non-steady-state Ridges

Assuming the possible non-steady-state ridges, we may distinguish between past changes in spreading rate and discontinuities in time, or lapses during which spreading was at a standstill.

An example of the latter is the hypothesis that no crustal spreading occurred between 40 or 50 mybp and 10 mybp[7] This accounts for the thinness of the axial sediments It also accounts for the narrow band in which heat flow is high. Indeed, it was the disagreement between observation and model that led Langseth *et al* [12] to suggest that the Mid-Atlantic Ridge has become reactivated during the past few million years after a lapse which lasted through most of the Tertiary. The lapse hypothesis accounts for several other characteristics of the ridge

To begin with, we shall examine the likelihood that ridges are not always active There is evidence for rifts in every stage of fossilization The Mid-Atlantic rift bifurcates into a number of major and minor branches north of 50° N. yet, on the basis of seismicity, vulcanism and magnetic anomalies, present activity is almost exclusively confined to a single narrow rift zone There are perhaps three major rifts at 55° N.: (1) the Labrador Sea rift, which is essentially inactive, although occasional small earthquakes occur[20]; (2) the Reykjanes rift, active at present, (3) an older rift between the European shelf and the Rockall–Faeroe ridge[21] South-western Iceland is marked by three rifts active during post-glacial times[17], but only one of these is now seismically active[20] Between Iceland and Jan Mayen Island there is evidence for a fossil rift now represented by a belt of seamounts in the Norwegian Basin east of Jan Mayen Ridge[22] In the Arctic Basin, the active branch is the Nansen Cordillera The Alpha Ridge appears to be a fossil ridge which became inactive during the Tertiary[23]. It is not yet known whether more than one branch was ever active at the same time, or if periods of quiescence preceded cracking in a new area The atypical crestal magnetic pattern and the aseismic nature of the ridge south and east of southern Africa also suggests that it is at present a dormant ridge[21]

In view of the evidence that many rift segments are presently inactive it is not presumptuous to suppose that crustal spreading may be rejuvenated at the axis of a temporarily inactive ridge The ridge is then no longer steady-state, but will reveal somewhere on its flanks a more or less sharp boundary between the old crust and the new. If this lapse in sea floor spreading is recorded by the crust at present between X_1 and X_2 from the axis of the ridge, the following are some of the possible geological and geophysical criteria by which it might be recognized (Figs 3 and 4)

(1) The topographic profile is steepened over a region that may be wider than X_1–X_2 because of heat exchange between old and new crust Fig. 1 shows how the ridge profile might appear after an idealized lapse (quiescent period) which lasted for 20 million years and ended 10 mybp This profile was derived by applying an isostatic correction to the 1 cm/yr model ridge profile[12] and assuming that subsidence of a parcel of crust depends in the first approximation only on the time after extrusion at the axis Fig 1–1 shows the ridge steady-state. Fig 1–2 shows the same ridge considerably subsided, at the end of a 20 million year lapse. The rejuvenated ridge, the crest of which has again attained the maximum of about 3 km elevation above the equilibrium level, is shown in Fig. 1–3 The mid-ocean ridge in the North Atlantic Ocean may be in such a condition

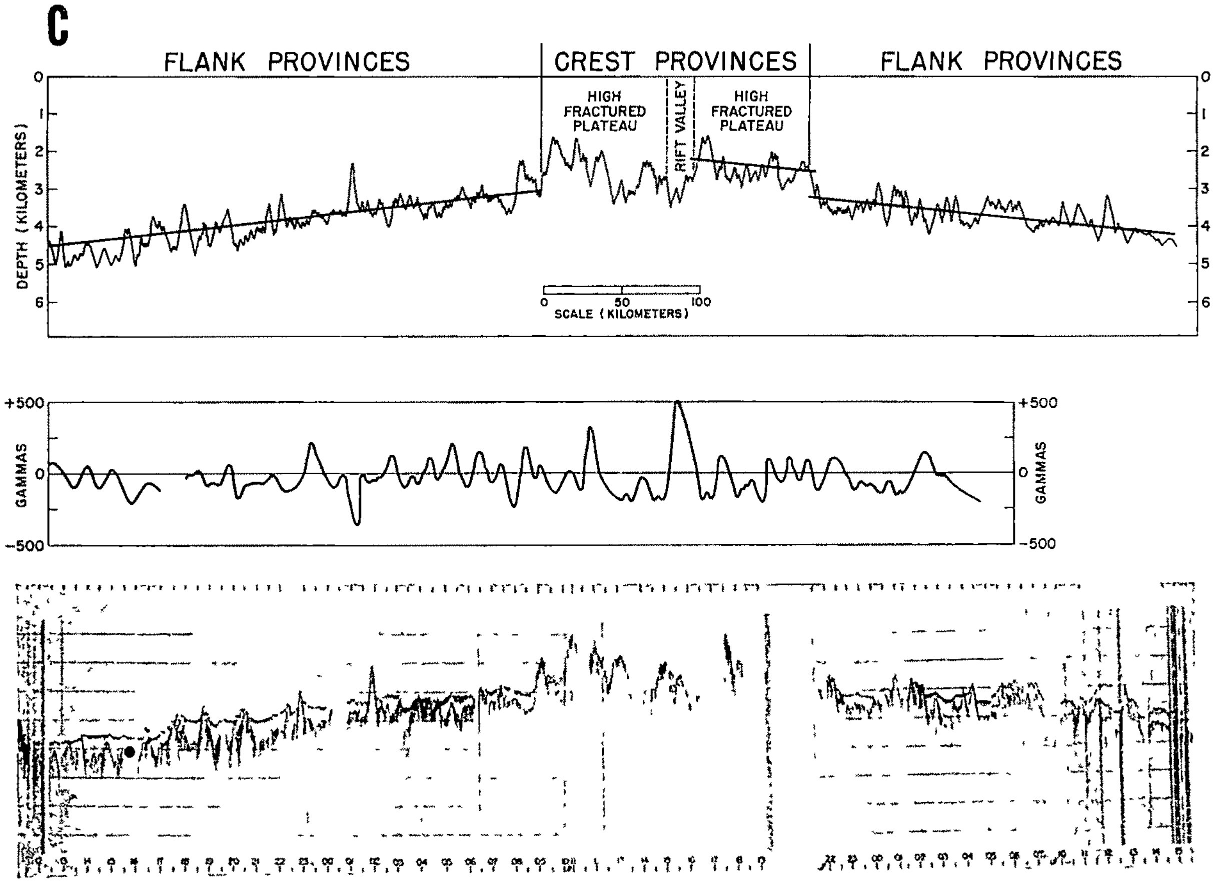

Fig 6 Profile C across Mid-Atlantic Ridge at 46° N Angle between profile and ridge is about 45° Original reflexion record is shown at bottom Straight lines were ruled through basement topography Province designations are based on Heezen *et al* [8]

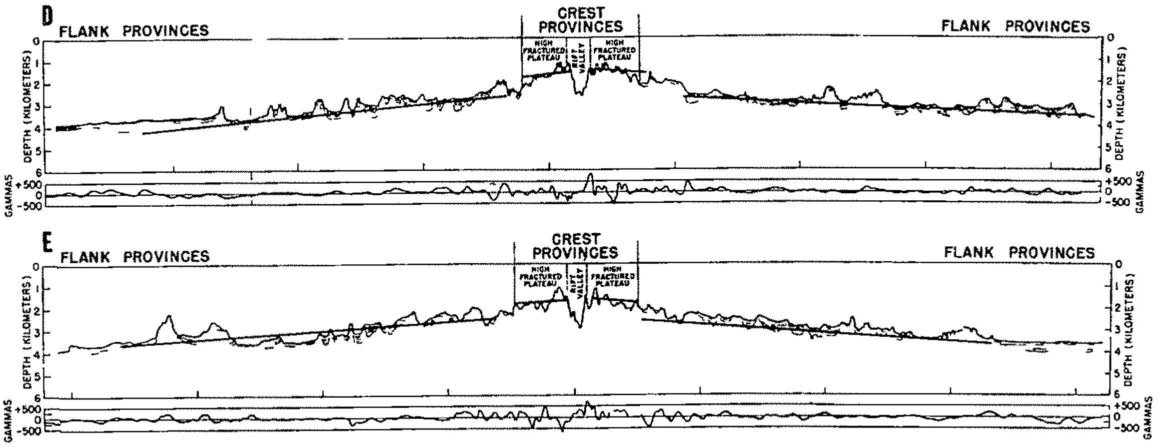

Fig 7 Profiles *D* and *E* across the Mid-Atlantic Ridge at 36° N, illustrating crestal province differing from adjacent flanks in basement roughness, magnetic signature, elevation and sediment thickness Angle between ridge and profiles is about 80° Tick marks at base of profiles are 100 km apart

(2) Sediment thickness increases sharply, if sedimentation rates can be assumed to have been constant

(3) Heat flow values diminish sharply The sharpness will depend on the age and length of the hiatus as well as the conductivity of the crust and upper mantle

(4) After magnetic profiles have been reduced to a constant elevation above the igneous basement, the magnetic pattern may differ on either side of X_1 and X_2 This implies that the hiatus could have marked a change in the frequency of polarity reversals and/or a change in spreading rates of the ridge The most powerful tool in establishing the existence and length of a hiatus would be a direct application of the Vine–Matthews technique[4], which requires a complete history of field reversals, determined from palaeomagnetic measurements and isotope dating, for a period of time at least long enough generously to bracket the hiatus If a certain sequence of reversals is missing in the oceanic crust at $\pm X$, the "magnetic tape recorder" must have been "turned off" for the corresponding period of time

In the absence of such a detailed dated history of polarity reversals—the exact reversal sequence has been extended only to 4 mybp at present—the existence and length of a hiatus could be established by the following relative technique If a complete sequence of reversals, as manifested by anomalies, is recorded on one part of the ridge system, it can be used as a standard of comparison for a part of the ridge where there is a hiatus, reflecting a lapse in spreading The length of the interval for which no crust was generated on the non-steady-state ridge is estimated by the length of the "missing" sequence of anomalies

(5) Isotope and palaeontological ages of the oldest rocks and sediments increase sharply

(6) The character of the subsedimentary crust seems to depend on spreading rate, so that past variations in this rate would have been recorded by the crust Menard[24] has observed that for $S < 2$ cm/yr, the crust that is generated is characterized by a thick "volcanic" layer, rough topography and the absence of an "oceanic" layer Conversely, $S > 2$ cm/yr is characterized by a thin volcanic layer, a smooth basement and an oceanic layer The time rate of generation of the volcanic layer seems to be relatively independent of spreading rate

In Fig 4, two possible combinations are shown schematically Fig 4–1 suggests a present rate less than 2 cm/yr and a past rate greater than 2 cm/yr The interval between is shown dashed It could be merely a transition from one rate to another, or spreading could have been slow or zero during the interval It is not known what the crustal structure might be for spreading rates much less than 1 cm/yr, or indeed if such rates are possible. The second example shows the crustal structure that would be expected if spreading dropped below 2 cm/yr for an interval of time and then rose above 2 cm/yr again

The following additional types of evidence for lapses in sea floor spreading are not restricted to the strips $X_1 < X < X_2$

(7) Volcanic activity might be different in volume and petrology before, during and after the quiescent interval The islands on the ridge would be expected to be most affected, but the possibility that volcanic activity at great distances from the ridge axis is also coupled to spreading rates cannot be discounted, especially if there is differential movement between the magma sources and the overlying crust

(8) The history of volcanic and tectonic activity along island arcs should reveal lapses in sea-floor spreading if the arcs constitute the crustal "sinks" corresponding to the mid-oceanic "sources"

(9) Orogenic and epeirogenic events on adjacent continents may correlate with events on the mid-oceanic ridge

Evidence for a Late Tertiary Lapse

Eleven crossings of the North Atlantic taken between 10° N and 46° N have collected magnetic, bathymetric and sediment thickness data (seismic reflexion) (Fig 5), which have been combined with published geological and geophysical data from the ridge Analysis of these data suggests that many known but unexplained characteristics of the ridge can perhaps be explained in the light of a hiatus in sea floor spreading

Most crossings of the North Atlantic show a distinct break in the topography at a distance of 60 to 130 km from the central rift (Figs 6–10) This break was first noted by Heezen *et al.*[8], who subdivided the ridge into crest and flank provinces with a marked steepening of slope between. The crest province is marked by local topography (800 m relief) which is rough compared with that of the flank provinces (400 m relief)

This steepening of the topographic profile is a distinct vertical topographic offset in the basement and is generally symmetric about the ridge axis The magnitude of the offset ranges from 0 5 to 0 7 km Fracture zones complicate measuring the offset in slope at several crossings of the North Atlantic (Figs 8 and 9), but the raised crestal block of the ridge is a feature that is easily seen in most exaggerated profiles The marked break in slope fits the model, suggested earlier in this paper, of a hiatus in sea floor spreading (criterion 1) During this hiatus the entire ridge subsided by thermal and petrochemical contraction A resurgence of activity was marked by renewed spreading and uplift of the crestal portions of the ridge The rate of uplift is unknown but, for example, the Colorado Plateau, which may constitute a rejuvenated segment of the East

Pacific Rise, has been uplifted at a rate of about 15 cm/1,000 yr since the Pliocene[25]

The variation of sediment thickness with distance from the axis of the Mid-Atlantic Ridge is also consistent with a late Tertiary lapse in sea-floor spreading (criterion 2) Seismic refraction data, cores and bottom photographs have all noted the scarcity of sediment on the crest of the ridge Early seismic reflexion data showed a marked lateral sediment thickness discontinuity on the Mid-Atlantic Ridge[26] Ewing and Ewing[7] have perhaps documented that this discontinuity is of world-wide extent Their best explanation of the phenomenon is a lapse or halt in crustal spreading during the Tertiary, followed by a later resurgence These and earlier workers, noting the thinning of sediment toward the ridge crests, suggested a younger age of the ridge towards the crest[7], but they failed to note that this sedimentary thickness boundary takes place at the well marked physiographic boundary between crest and flank, indicating a marked age difference between these two adjacent provinces

The lateral discontinuity in sediment thickness is evident in the seismic reflexion data despite marked differences in absolute thickness along the strike of the ridge The crossing at 12° N (Fig 10) reveals only 200–400 m of sediment on the ridge flanks, whereas the thickness at 46° N. (Fig 6) ranges from 600 to 1,400 m Yet in both regions the ratio between sediment thickness on the crest and that on the immediately adjacent flanks ranges between 1 2 5 and 1 . 5

Sediment thickness on the ocean floor is controlled by (1) age of the underlying crust, (2) biological productivity and (3) proximity to sediment sources and sediment distribution systems

Air gun and sparker seismic records across the ridge crests show little sediment in this province (less than 100 m) and no noticeable thickening of sediment occurs from the rift to the crest-flank boundary (Figs 6 and 10) Records across the flanks also show no noticeable thickening away from the crest

This observation raises a problem, because uniform sea-floor spreading would appear to demand a monotonic increase of sediment thickness with X, the distance from the crest of the ridge

This dilemma might be resolved by allowance for the steadily changing sedimentation regime "seen" by a parcel of crust as it rides down the "subsiding conveyor belt". For example, the lack of apparent sediment thickening down the flanks may be due to a change from the relatively rapid pelagic rates (1 cm/1,000 yr foram ooze) to the slow rates prevailing in the red clay zone below the level of carbonate compensation (0 1 cm/1,000 yr) In the crest province, the lack of noticeable thickening of sediments away from the younger central rift perhaps stems from techniques of seismic measurement It is also known from bottom photographs that, near the crest, currents are filling in small crevices and valleys with sediment

The heat flow data under "steady-state ridges" are also consistent with the lapse hypothesis High values occur on the high crestal block and are flanked by essentially average values (criterion 3) Magnetic anomaly patterns across the ridge show a change in anomaly pattern from crest to flank with longer wavelength and lower amplitude anomalies prominent on the flanks[13] (criterion 4) This marked change takes place at the fifth major positive anomaly from the crest or at about 10 mybp (ref 21) (Figs 7 and 8) Such change in the character of the anomaly pattern at this boundary either marks (1) a change in the frequency of polarity reversals or (2) a change in the rate of ridge spreading (Fig 3)

Avery *et al* [27] have analysed a detailed aeromagnetic survey of the Norwegian Sea by comparing the anomaly sequence observed there with a "standard sequence" established by several workers at the Lamont Geophysical Observatory (see ref 5 for example) This sequence applies to the mid-oceanic ridge in the North and South Pacific and South Atlantic On the assumption that ridge spreading has been continuous on these ridges, Avery *et al* [27] while admitting the tentative nature of their conclusions, propose the following history for sea floor spreading in the Norwegian Sea The first episode of spreading lasted from 60 to 49 mybp at a rate of 1 4 cm/yr A second period of spreading seems to have lasted for 20 million years (assuming $S = 1$ cm/yr) This interval may or may not have been continuous with the first spreading episode and ended considerably before 10 mybp There was a long period of quiescence, with renewed spreading beginning 10 or 15 mybp on Iceland-Jan Mayen and Mohns ridges The relative magnetic correlation technique (under criterion 4) therefore supports the proposed late Tertiary lapse, at least on the northern extension of the Mid-Atlantic Ridge

As yet, the geomagnetic reversal time scale is not complete enough to establish the exact length of the hiatus The present rates of spreading provided by studies of sea-floor magnetic patterns are approximately consistent with various geological estimates for the time at which rifting began So if we invoke a stoppage in sea floor spreading, it must either be short compared with the overall time of opening the basins or we must invoke higher spreading rates in the past

The distribution of isotope and palaeontological ages away from the ridge crest (criterion 5) is poorly known[11], but the data at least do not preclude the lapse hypothesis

Recent work[28] has revealed a strong correlation between the petrology of oceanic rocks in the Atlantic and Pacific and the distance from the mid-ocean ridge axis Basalt specimens collected within the belt of high heat flow around the crest are strongly oversaturated with silica, whereas undersaturated alkaline rocks appear on the

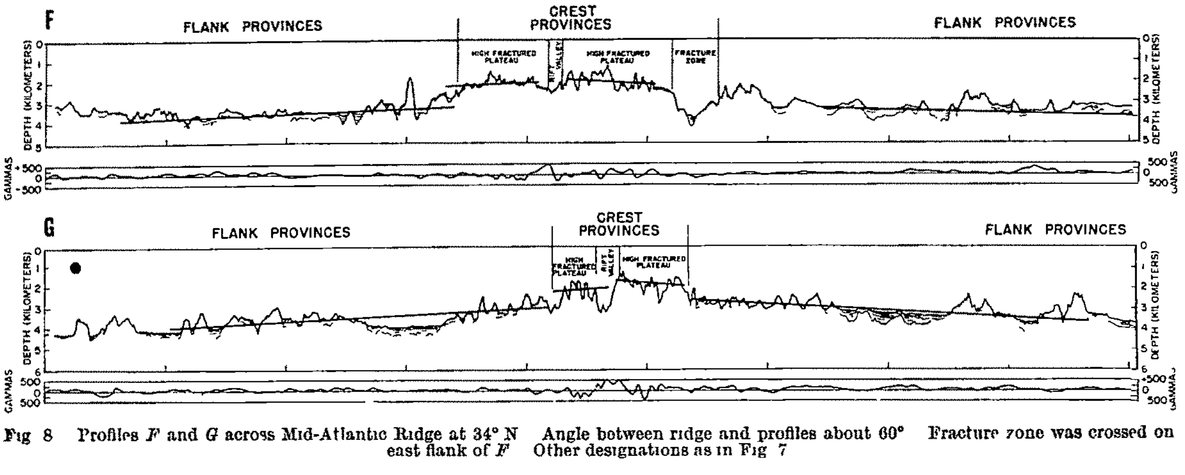

Fig 8 Profiles *F* and *G* across Mid-Atlantic Ridge at 34° N Angle between ridge and profiles about 60° Fracture zone was crossed on east flank of *F* Other designations as in Fig 7

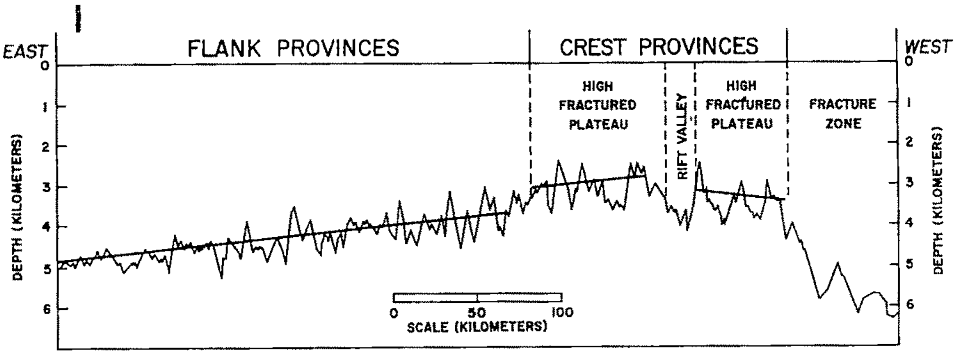

Fig 9 Profile *I*, crossing Mid-Atlantic Ridge perpendicularly at 18° N Profile crosses fracture zone on west flank Other designations as in Fig 6

flanks and in regions far from the crests. Perhaps the petrology of rocks injected since rejuvenation of rifting differs systematically from that of rocks antedating the lapse (criterion 7)

Geological evidence from an active island arc also supports the late Tertiary lapse in crustal spreading (criterion 8) In his studies of the West Indies, Professor T W. Donnelly has concluded that the period between about 40 and 10 mybp was marked by little or no volcanic activity, and the erosion of older lavas Uplift and a renewal of vulcanism began about 10 mybp (personal communication from T W Donnelly) Detailed studies should be made to attempt to correlate orogenic and epeirogenic events on island arcs and continents with the proposed Tertiary lapse in spreading (criterion 9)

Evidence for Other Discontinuities

There is some evidence for several other discontinuities which may, however, only involve changes in rate of spreading Phillips[29] has found an apparent discontinuity in rate which occurred 5 to 6 mybp and involved a decrease of 18 to 27 per cent This change was observed at 22°N and 27° N on the Mid-Atlantic Ridge and resembles a similar discontinuity on the Juan de Fuca Ridge Because the absolute magnetic reversal time scale has not been established, the discontinuity in spreading rate may not be real

Another discontinuity in rate may exist between 300 and 400 km from the axis of the northern Mid-Atlantic Ridge At about 300 km the crustal section is still typical of "slow" ridges, for there is 3 km of second layer overlying low-velocity mantle[13] At 400 km, this abnormal mantle is replaced by 5 km of oceanic layer overlying a normal mantle[13]

The wavelength of this dominant magnetic anomaly changes from 32 km to 36 km at $X=300$ km[16] If no change in the average reversal rate occurred, this implies a 12 per cent decrease in spreading rate The time of this change cannot be established, for the subsequent spreading history is not known precisely. If the average spreading rate has been 1 5 cm/yr, the discontinuity occurred at 20 mybp (if there has been no Tertiary lapse) or at 50 mybp (if there was a lapse of 30 million years as suggested by Ewing and Ewing[7] and by these arguments) An effort should be made to find changes in average topographic slope and in thickness of the volcanic layer on either side of the 300 km discontinuity The change in the magnetic spectrum implies a 12 per cent decrease in both regional slope and thickness of the volcanic layer between 300 and 400 km. The change in slope follows if subsidence is primarily a function of time after extrusion The change in thickness of the volcanic layer follows if the time rate of discharge of this layer is constant in time[24]

At about 700 km, in the North Atlantic, the regional slope decreases from about 3 1000 to 1 5 1000 or less. This break is the outer boundary of the Mid-Atlantic Ridge, as defined by Heezen *et al* [8]. At the same distance, the dominant magnetic wavelength increases from 36 km to 70 km[16], suggesting a 50 per cent decrease in spreading rate if the frequency of polarity reversals did not change at that time The age of this boundary would be 65 mybp if the spreading rate has been 1 5 cm/yr except during the late tertiary lapse This age, which coincides with the Laramide orogeny, may mark the time when the Atlantic rift propagated northward from about 50° N. into the Arctic Ocean[30]. The 50 per cent decrease in spreading rate should have been marked by a 50 per cent increase in the thickness of the volcanic layer, because the time-discharge rate for the volcanic or "second", layer is postulated to be constant for mid-ocean ridges[24] Indeed, seismic refraction profiles in the deep basins of the North Atlantic Ocean do not reveal first arrival returns from the layer[31] Thus if the second layer exists under the deep basins, it must be quite thin

The spreading rate prior to the 700 km discontinuity (about 3 cm/yr if magnetic anomaly wavelengths are indicative) may be extrapolated to the east coast of the United States, suggesting a Jurassic age for the oldest parts of the North Atlantic As a check on this reconstruction of spreading, we note that the isotopic ages of dolerite dikes thought to have been emplaced during the initial stages of North Atlantic rifting fall between 140 and 180 mybp[31]

By contrast, Heirtzler and Hayes[32] have extrapolated a 1 cm/yr rate to the edges of the continents and have concluded that the undisturbed magnetic field near the continental margins should be assigned to the Permo-Triassic, making the North Atlantic up to 250 million years or more old In view of the more recent spreading rate determinations at these latitudes[29] as well as the inferences presented here, the North Atlantic is no older than lower Jurassic Geological evidence suggests that the East African stage of rifting (before there was an ocean) is recorded by the Upper Triassic grabens the sedimentary fill of which is grouped under the Newark series.

We have suggested a major discontinuity in time and possibly spreading rate at about 100 km, and discontinuities in rate at about 300 and 700 km The topographic effect of the late Tertiary lapse is still pronounced. This discontinuity is the boundary between the High Fractures Plateau and the Upper Step in a physiographic classification of the Mid-Atlantic Ridge[8] Similarly, the 700 km discontinuity coincides with the distal boundary of the lower step. It is tempting to suppose that the boundaries Upper/Middle and Middle/Lower also reflect spreading rate discontinuities The upper one may be related to the 300 km discontinuity If marked elevation differences separate the steps, time discontinuities (lapses) may also be involved The absence of marked changes in the thickness of unconsolidated sediment across the features suggests, however, that the lapses, if any, were short.

The late Tertiary quiescent interval recorded by the mid ocean rift in the North Atlantic seems to be correlated with a period of slower spreading (but not stoppage) on the East Pacific Rise Menard[24] has cited evidence that spreading rates were 4 cm/yr before and after this period During the period of slower spreading (1 5 cm/yr ?)

belts of rough topography about 200 to 500 km wide were generated The centres of these belts are now about 500 to 1,000 km from the axis of the East Pacific Rise If the "slow" period corresponds to the North Atlantic hiatus, the width of the belts should equal the spreading rate (1·5 cm/yr) times the length of the hiatus (30 million years), or about 450 km This is in good agreement with the observed width of the belts A further check on this hypothesis is the width of the axial belt of smooth topography on the East Pacific Rise If fast spreading (4 cm/yr) began 10 mybp, the width of the smooth belt should be 2 × 4 cm/yr × 10 my or 800 km, which also agrees with observation The activity on the East Pacific Rise and the Mid-Atlantic Ridge seems to be remarkably synchronized

The East Pacific Rise therefore reveals the type of discontinuity of spreading shown schematically in Fig. 4 Seismic refraction profiles in Menard's "horstgraben provinces" would be of great interest If the second layer is generated at a constant rate in time[24], this layer should be 3 km thick under these parts of the East Pacific Rise By analogy with the Mid-Atlantic Ridge, there should be no oceanic layer but a low-velocity mantle (Fig 4)

Conclusion

Seismic reflexion, topography, heat flow and magnetic data seem to support the suggestion by Ewing and Ewing[7] that there was a late Tertiary lapse in crustal spreading which ended about 10 mybp This lapse has been recorded by the crust and is now about 100 km from the axis of the Mid-Atlantic Ridge The magnetic reversal sequences on the East Pacific, Carlsberg, and South Atlantic branches of the mid-oceanic ridge exhibit one-for-one correlations after linear differences in spreading rate have been removed[27] Because much of the evidence for the late Tertiary lapse applies to these areas as well, the lapse must therefore be assumed to have been a global phenomenon, although the history of crustal spreading seems to have been more complex on the Mid-Atlantic Ridge north of about 50° N

We are not now prepared to suggest a firm length of the period of ridge quiescence or slow-down Sediment thickness ratios between crest and flank are variable and several unknown factors must be considered in calculating the rates of subsidence of a cooling ridge flank. Present values suggest, however, a period of quiescence of 15 to 30 million years Topographic, seismic refraction and magnetic data also suggest that two other discontinuities in the spreading rate (decreases) may be recorded by the crust in the regions 300 to 500 km and, less certainly, at 700 km from the axis of the Mid-Atlantic Ridge Careful statistical work on topography, heat flow, dating, sediment thickness, magnetics and crustal structure in the transitional regions is required to substantiate these events and correlate them with those found on other ridges and with orogenic events in general

The history of spreading is still too incompletely understood to rule out the possibility that rifting may shift between one part of the ridge to another on a global scale in such a way that sea floor is created at a constant rate in time, as measured around a great circle The latter would be expected if the world is presently expanding at a constant rate in time[33,34] If the entire mid-oceanic rift shows synchronized periods of activity and quiescence, the expansion hypothesis must invoke processes that can operate with periods measured in tens of millions of years If sea floor spreading is driven by a global convection cell a simultaneous stopping and starting along the entire Mid-Atlantic Ridge and East Pacific Rise implies that different parts of the cell are very closely coupled in time, with convection speeds varying slowly and apparently regularly along the strike of the ridge Some of this synchronization could be understood if the strength of the healed crust can appreciably exceed the tension stresses on it As stresses build up there will be an area of weakness where rifting begins, and the rifting will propagate, if it is analogous to a crack, over wide regions, passing into weakly stressed and even into unstressed and compressional regions The rift will preferentially follow lines of pre-existing weakness[35] A pre-existing rift will be preferred because it is a "flaw", but the greater the quiescent interval the greater the probability that a new site will be chosen If convection cells are involved, a change in their position would favour a new locus of rifting Interesting possibilities arise, however, if the crust has significant strength The rising limbs of deeper convection cells might be considerably displaced from the ridge axis The ascending cell could be very broad indeed, while mantle derivatives are continuously injected into a narrow zone of constant weakness The regularity of crustal spreading may therefore be partly due to the localization of fracturing along a continuously rejuvenated zone of weakness

If the crust has significant strength, a world-wide cessation of rifting is more difficult to understand, because crustal spreading along pre-existing lines of weakness—along the axis of the mid-oceanic rift—is so much "easier" than a renewal of activity. But granted the tensional forces may decline in time over a large region, possibly the whole world, it is possible to account for a sudden, synchronized stoppage. As tension decreases, spreading

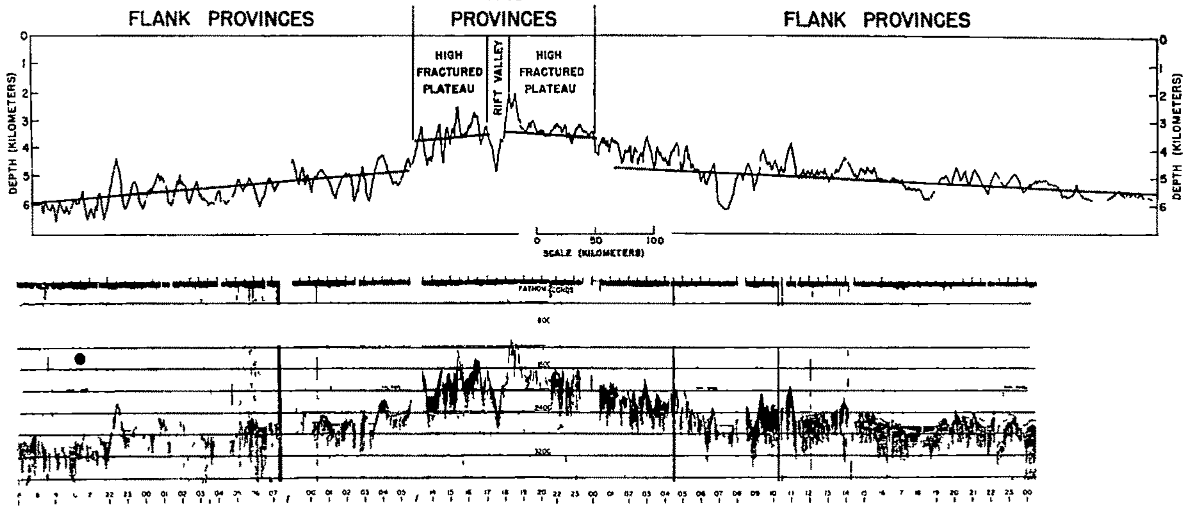

Fig 10 Profile *J*, crossing Mid-Atlantic Ridge perpendicularly at 12° N Other designations as in Fig 6

rates fall. Meanwhile, the thickness of the solid crust increases by downward freezing and by cooling. Tensional fissuring will continue throughout the rift until the weakest or most highly stressed region can no longer sustain crustal spreading by extending the process to neighbouring and stronger regions. There is then a synchronized end to crustal spreading, on a large and possibly global scale.

The evidence for major discontinuities in the history of crustal spreading is still speculative. It is of great interest to know whether the mid-oceanic ridges can be considered steady-state for periods of the order of 10–100 million years. If they can, the variation of crustal structure with X implies a rate. That is, the rates at which physical processes occur in the Earth and the conditions under which they occur could then be deduced by careful study of how a mid-ocean ridge changes away from its crest. Unlike the study of oceanic or atmospheric circulation, where the validity of "steady-state" approximations can be checked by repeated surveying, the upper mantle processes must take millions of years to establish physicochemical equilibrium. The exact history of crustal evolution and spreading thus awaits detailed application of the Vine-Matthews hypothesis[4] to the whole ridge system, and the possibility of discontinuities in the spreading history must be carefully considered and checked out by all possible means.

Rapidly Pulsing Radio Sources

by

WILLIAM C. SASLAW

JOHN FAULKNER
PETER A. STRITTMATTER

Institute of Theoretical Astronomy,
Madingley Road, Cambridge

The gravitational lens effect associated with a neutron star binary gives results which agree well with recent observations of a new class of rapidly pulsing radio sources. Further tests of the theory are proposed.

OBSERVATIONS of a new type of rapidly varying radio source have recently been reported[1]. The principal characteristics of the four sources so far discovered may be summarized as follows—sharp pulses of radiation are received, separated by comparatively long intervals which themselves are remarkably constant (with variations of $\lesssim 1$ part in 2×10^7 during the past 3 or 4 months). The pulse duration is no more than ~ 0.016 s, while the period is 1.3372795 ± 0.0000020 s (ref. 1). We understand that the other objects show similar sharp pulses at intervals of the order of 1 s, which, although not identical, strongly suggest that a new type of physical system has been discovered. Hewish *et al.* propose that the objects may be pulsating white dwarfs or neutron stars. Although this may prove to be correct, there are certain difficulties associated with the constancy of the observed period. We suggest an alternative explanation for the observed phenomena.

Gravitational Lens Hypothesis

An obvious method of achieving astronomical regularity is that associated with motion in a binary system. We therefore suggest that the radiation peaks are caused by the nearest member of a binary pair acting as a gravitational lens on the radiation of its more distant companion. The observed interval between emission bursts for objects of equal mass would be one-half the orbital period. It might be thought that such occurrences would necessarily have a negligible probability. Remarkably, this is not the case.

We first embark on an approximate illustrative analysis, to be followed by more detailed computations. Consider the motion of two stars of equal mass $M \sim 0.5\ M_\odot$ and with an orbital period of 3 s. This corresponds to a separation $a \approx 3 \times 10^8$ cm and orbital velocities $\sim 10^{-2}\ c$. Clearly, it follows from the small separation that the stars must be very compact white dwarfs or neutron stars. This requirement is also necessary for the gravitational lens mechanism to be effective.

Liebes[2] has given a theoretical discussion of the gravitational lens and we shall follow his notation throughout. Fig. 1 illustrates the configuration. O, D and R denote the source, deflector and receiver, respectively. $2\varphi_O$ and $2\varphi_D$ denote the undistorted angular diameters of O and D, if they could be seen by the receiver. The semi-apex angle of the "cone of inversion" is given by

$$\theta_0 = \left(\frac{4\,G\,M_D}{(1 + l_D/l_{OD})\,l_D\,c^2}\right)^{1/2}$$

$$\approx\left(\frac{4\,G\,M_D}{c^2\,l_D}\quad\frac{l_{OD}}{l_D}\right)^{1/2} \qquad (1)$$

because in our case $l_D \gg l_{OD}$ M_D denotes the mass of the deflector As the source moves behind the deflector the receiver sees two images I_1 and I_2 on either side of the cone of inversion These images merge to produce an annulus round the cone of inversion in the unlikely case when O, D and R are perfectly aligned Because the brightness remains the same along a light path, the amplification factor A is given by the ratio of the total solid angle subtended by the deflected images to the undistorted solid angle of the source Thus Liebes obtains

$$\begin{aligned} A &\approx 1,\ \alpha>\theta_0 \\ &\approx \theta_0/\alpha,\ \alpha<\theta_0 \end{aligned} \qquad (2)$$

with a maximum value

$$A_{\max} \approx 2\theta_0/\varphi_0 \qquad (3)$$

in the case of perfect alignment These results are subject to the conditions that all deflexion angles are small and that the geometrical cross-section of the deflector is too small to block much radiation This last condition implies that

$$\frac{\theta_0}{\varphi_D} = \left(\frac{4\,G\,M_D}{c^2\,r_D}\right)^{1/2}\left(\frac{l_{OD}}{r_D}\right)^{1/2} \gg 1 \qquad (4)$$

where r_D is the deflector radius Condition (4) can be satisfied only when $l_{OD}/r_D \gg 1$, because the first term in brackets is essentially the Schwarzschild parameter With the estimated value of l_{OD} ($\equiv a$) given here, this implies that the deflector cannot be a white dwarf and must therefore presumably be a neutron star Similarly, to obtain substantial amplification, we require that

$$A_{\max} \approx \frac{2\,\theta_0}{\varphi_0} = 4\left(\frac{G\,M_D}{c^2\,r_O}\right)^{1/2}\left(\frac{l_{OD}}{r_O}\right)^{1/2} \gg 1 \qquad (5)$$

which again demands that the source be a neutron star We are led therefore to a binary system consisting of two neutron stars, each acting as a gravitational lens for the other

In the following discussion we will consider only those cases in which reasonable amplification ($A \gtrsim 2$) is obtained The receiver R will not usually be in the orbital plane of the stars and we define χ to be the angle of closest approach as seen by R The situation is illustrated in Fig 2, in which the path of O is taken to have negligible curvature within the cone of inversion This is a good approximation provided $(4GM_D/l_{OD}c^2)^{1/2} \ll 1$, which is easily satisfied in the present case Clearly the largest amplification $A_{\rm m}$ for a given path is

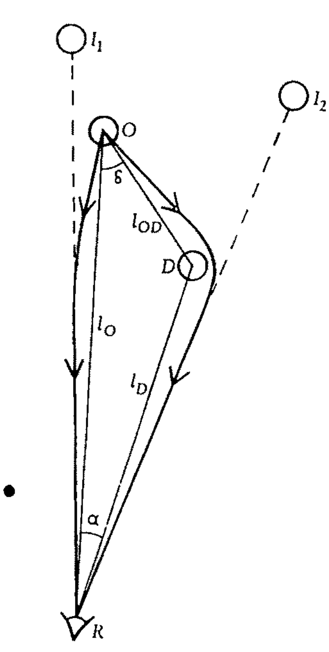

Fig. 1. Geometric configuration and typical light paths for gravitational lens

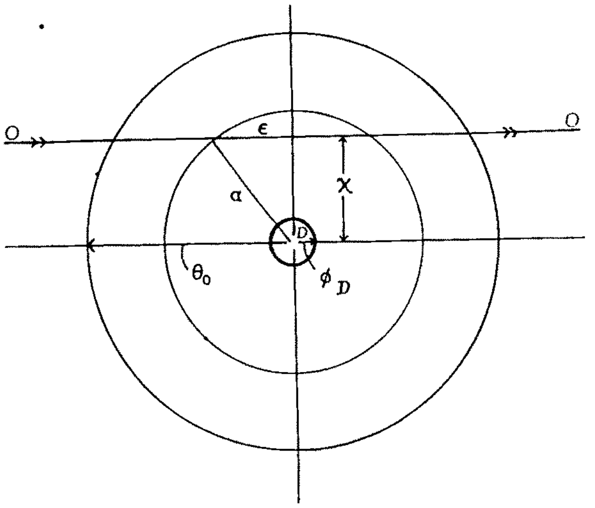

Fig 2 Path of centre of source ($O-O$) compared with cone of inversion

$$A_{\rm m} \approx \theta_0/\chi = \frac{\varphi_0}{2\chi_0}\quad A_{\max} \qquad (6)$$

The angle δ_A ($\angle DOR$) at a given amplification is then given by

$$\begin{aligned} \delta_A &= (l_D/l_{OD})\alpha = l_D\theta_0/A \\ &= (1/A)\ (4GM_D/l_{OD}c^2)^{1/2} \end{aligned} \qquad (7)$$

The time interval between points of given amplification in a single pulse is thus given by

$$T_A = (\delta_A/\pi)\xi P \qquad (8)$$

where

$$\xi = A\varepsilon/\theta_0 = (1-A^2\chi^2/\theta_0^2)^{1/2} \qquad (9)$$

provided, of course, that the required amplification is reached, and that $A \lesssim \theta_0/\varphi_0$ If we demand, for example, an amplification of $A=3$ and use the approximate values of M_D and l_{OD} assumed here, we obtain $\delta_3 \approx 10^{-2}$ and $T_3 \lesssim (\delta_3/\pi)\ P \simeq 10^{-2}$ s This time certainly satisfies the condition $T \lesssim 0\ 016$ s given by Hewish *et al* and suggests that, with entirely reasonable estimates of M, the observed characteristics of the signal can be reproduced

The actual amplification as a function of ε is illustrated in Fig 3 for the cases $\chi=0$ and $\chi=\theta_0/3$ In the former case the maximum is determined by φ_0 Clearly the width at given amplification is directly related to T_A Thus by increasing the amplification factor the steepness of rise can be increased and the width of the pulse reduced The apparent shape of the signal will then depend on the residual signal level (RSL)

If it is assumed that the whole surface of a neutron star acts as the effective source, there is clearly an upper limit to the maximum amplification This is because there is an upper bound M_c to the mass of a stable neutron star configuration, and a corresponding lower bound r_c to its radius Meltzer and Thorne[3] give values of M_c and r_c for two assumed equations of state, one due to Harrison, Wakano and Wheeler (HWW), the other to Skryme, Cameron and Saakyan (SCS) Of these the latter give the most favourable values of r_c and M_c, from which it follows that the maximum possible amplification is

$$A^*_{\max} \approx 17\ P^{1/3} \qquad (10)$$

The HWW values give the coefficient of $P^{1/3}$ as ~ 10 These limits can be relaxed, however, if the stars have significant angular momentum or if a further hard core pressure (the C-field[4], for instance) exists More important, if the radiation comes from smaller regions on the stellar

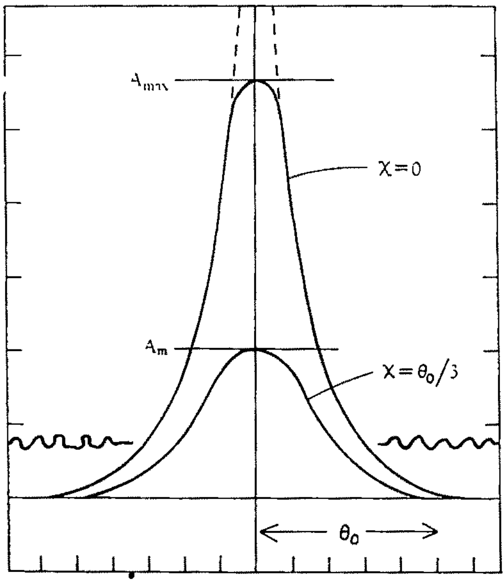

Fig. 3. Typical individual pulse shapes for angular impact parameters $\gamma=0$, and $\chi=\frac{1}{3}\theta_0$.

surface, from flares for example, the value of $A^*_{\max}$ can be exceeded by large factors. This question will be discussed further in the following section in which we attempt a comparison of our proposal with the pulsating star hypothesis.

Comparison of Binary and Oscillation Theories

We now list some of the observational and theoretical problems raised by the new radio sources and examine them in the light of the theoretical explanations so far proposed.

(i) Random Signal Strengths

It appears that the signal amplitudes vary considerably from pulse to pulse, disappearing below RSL for a considerable proportion of the time. On the binary star theory there is clearly no reason to expect correlations between successive pulse intensities because the "clock mechanism" (the gravitational orbit) is completely divorced from the energy source. Random flares occurring on each star or in the region between stars happen to be amplified, and thus observed, only at moments of suitable alignment. We note, however, that if the flare lifetimes were significantly longer than the orbital period one would expect to observe their effects over several pulses. This may be the explanation for the observation[1] that, typically, the pulses are only present for about 1 min, which may occur quite randomly within the 4 min interval permitted by the reception pattern. Indeed any evidence for (even temporary) correlations between alternate pulse strengths would argue strongly for the binary theory, since this would have a natural explanation in terms of unusual activity on one star only. Hewish[1] has reported that several alternate pulses were very weak for one of the objects.

On the other hand, it is difficult to understand how an oscillating star can be tuned so finely that its period changes systematically by less than ~ 1 part in 10^{13} per cycle, yet can trigger pulses of completely random intensity. As a general rule, the shorter and more regular the period of a vibrating star, the more precisely repetitive is the energy output as a function of phase.

(ii) Sharpness of Signal

In the binary theory the apparent sharpness of the signal peak is determined by three main factors—the degree of alignment, the ratio of pulse strength to RSL and the angular diameter of the source (see Fig. 3). As we have noted, there is a maximum possible amplification factor $A^*_{\max}$ (equation (10)) if the emissivity is uniform over the surface of the source. If, as is more likely, flares occur over smaller regions of size $\sim r_f \ll r_O$, the value of $A_{\max}$ is enhanced by a factor r_O/r_f and the energy requirements at the source are reduced by r_f/r_O. The shape or changing position of the flare on the surface of the source could lead to some signal asymmetry, though in general we would expect this to be small. The duration of the flatter portion at the peak relative to the steepness of rise and fall depends on $A_{\max}$ and the residual signal-level and could, provided the source were single, be used in the determination of these parameters.

We should, however, point out that if there were a number of flare zones on a star the signal received would consist of a quick succession of bursts of the type illustrated in Fig. 3. The duration T_c of this combined signal would be determined essentially by the time for the stellar disk to cross the cone of inversion. Thus

$$T_c \approx (1+\varphi_0/\theta_0)\,T_1 \qquad (11)$$

If $\varphi_0 > \theta_0$, T_c could be rather longer than the times computed in the previous section. In this case, the general emission from the star would be unamplified whereas that from each flare zone would be amplified by A as given in equations (2) and (3) with r_O replaced by r_f. In this case, the sum of individual pulse lifetimes must be rather less than the time, T_c, over which the pulses are received, if the basic source is to remain below the level of detection (assumed the same for pulsing and constant sources). (In the previous section we excluded the possibility that the source is a compact white dwarf. If, however, the signals come from a small region on such a star, substantial values of A could still be obtained although the general emission would remain constant. The situation would, however, be far more complicated and is not covered by the small angle analysis.)

The oscillation theory has to explain both sharp rises and falls in the emission at the source. It is possible to imagine a situation in which shocks generated by the pulsations decay in times $\lesssim 0.016$ s, though it is not clear why this should always be the case. Nor is it clear why an oscillating star, tuned to 1 part in 10^{13} per cycle, should produce such shocks for only part of the time. Although such mechanisms may indeed exist, the explanation must certainly be much more complicated than that involving binary stars.

(iii) Probability of Observation

It is obviously necessary in both theories to estimate the probability of observing the required configurations. We take as common ground to both theories that neutron stars are the end point of evolution of stars of mass $\gtrsim 1.5\,M_\odot$. We list below the further assumptions that underlie our calculation.

(i) The luminosity function of the galaxy has remained essentially constant.

(ii) On the upper main sequence $L \propto M^3$, L being the luminosity of a star.

(iii) A star of $\sim 1\,M_\odot$ evolves completely in $\sim 10^{10}$ yr, the age of the galaxy also being of this order.

(iv) The lifetimes of radio bright neutron stars are long.

(v) *a*, A proportion q_1 of upper main sequence (UMS) stars become binary neutron star systems with periods in the region of a few seconds. *b*, A proportion p_1 of UMS stars become single neutron stars with negligible rotation.

(vi) *a*, Orbital planes of binary systems are randomly oriented in space. *b*, A proportion, p_2, of neutron stars have central densities in the correct range to give pulsation periods in the region of a few seconds.

Assumptions (i)–(iii) and (vi)*a* are reasonable and require no comment. We will give the remaining assumptions further attention.

From assumptions (i)–(iii), and using Allen's[5] tables, we find that n, the number density of completely evolved massive stars, is given by

$$n \approx 4 \times 10^{-3}\ \text{pc}^{-3} \tag{12}$$

a value common to both theories.

From assumption (v) *a* the number density of binary neutron star pairs is nq_1. Given (vi) *a*, the probability of the observer lying sufficiently close to the orbital plane to see an amplification A is given by the appropriate δ_A derived from equation (7). Thus the number density n_b of suitably oriented pairs is given by

$$n_b \simeq n q_1\, \delta_A \tag{13}$$

If $A \approx 3$, then $\delta \approx 10^{-2}$, and it follows that the expected number of favourable configurations within ~ 65 pc (the upper limit to distance given by Hewish *et al.*) is $\sim 40\, q_1$. We suggest that q_1 may be of order unity. In support of this, we note that the progenitors in general possess considerable angular momentum, and on contraction are likely to break up into two orbiting masses, according to a well known theory of double star formation[6,7]. Furthermore, a main sequence star is likely to reach the neutron star state via some sort of white dwarf configuration (non-static) which should be in a state of extremely rapid rotation and should break up as soon as any major contraction occurs. Thus an orbital separation of approximately a white dwarf radius ($\approx 10^8$–10^9 cm) and a period of order ≈ 1 s is not implausible. Angular momentum requirements are easily met because typically we require only $\sim 1/100$ of the angular momentum to be retained by $\sim 1/5$ of the mass. Furthermore, we note that because of the rapid rotation of UMS stars it is entirely plausible that multiple fission occurs leading to more than one neutron star binary pair[8]. We emphasize that this is extremely speculative but note however that among UMS stars the number of binaries, presumably formed during the Hayashi contraction phase, is comparable with the number of single stars. Thus a value of $q_1 \approx \frac{1}{2}$ seems not unlikely. It leads to about 20 binary neutron star systems within 65 pc having orbits sufficiently aligned for reasonable amplification. The suggested mechanism cannot therefore be excluded on probability grounds, subject, of course, to the condition that the binary system lifetime is long.

In the oscillation theory the number density of candidates n_p, corresponding to n_b is given by

$$n_p = n p_1 p_2 \tag{14}$$

The angular momentum difficulty suggests $p_1 \ll 1$. The calculations of Meltzer and Thorne[3] indicate that the pulsation period of a neutron star is extremely sensitive to the central density. Thus unless there is some particular mechanism which selects periods of 1 s it follows that $p_2 \ll 1$. (For white dwarfs it is necessary for the oscillation to be in an overtone mode if the observed period of ~ 1 s is to be obtained; this again indicates a low probability.) It therefore appears that n_p cannot significantly exceed n_b and may in fact be rather smaller. Neither theory can, however, be excluded, subject to the assumption of long lifetimes. We now consider this question.

(iv) Constancy of the Period and Energy Requirements

Hewish *et al.* have estimated the energy output of the first source to be $\sim 10^{47}$ ergs yr^{-1} provided it is at a distance of 65 pc. This is an extremely tentative figure, even apart from the uncertainty in the distance, because the spectral distribution is still not known in any detail. We will assume in the following discussion, *faute de mieux*, that this figure is correct. We defer discussion of energy radiated by gravitational waves until later in the paper.

It is important for theoretical purposes to place restrictions on the permissible amount of *systematic* change of period per cycle. From the present data it appears that the period is constant to at least one part in 10^{13} per cycle.

We remark that there is no variable red-shift problem for the binary model. The amplification can occur only when the motion is transverse. We further note that a change in mass would alter the periods in either model. The estimated changes due to accretion are, however, many orders of magnitude too small to have significant effects in either case.

If we assume that the oscillating star contains the maximum possible vibrational energy ($\sim 10^{51}$ ergs), the estimated radiation rate at 65 pc ($\sim 10^{47}$ ergs yr^{-1}) yields a decrease in vibrational energy of ~ 1 part in 10^4 yr^{-1} and presumably a similar change in amplitude. Although in a linear theory the period is independent of the amplitude of pulsations, a residual dependence on terms of higher order would be expected, particularly near maximum amplitude. The observed constancy to 1 part in 10^6 yr^{-1} appears to show a remarkable and, we think, unlikely absence of such non-linear effects. This argument can be countered by reducing the distance to the source by a factor of at least 10, but only at the expense of a further reduction in the expected number of stars to $n_p \simeq 4 p_1 p_2$. This is now disturbingly small.

The figures given here point clearly to a further difficulty. If the estimated emission rate is correct, the lifetime T_p of the pulsations can be at most $\sim 10^4$ yr. (Indeed, T_p is probably less than this because, according to Meltzer and Thorne[3], much of the available energy will be dissipated rapidly (in ~ 10 yr) by various processes including neutrino emission.) On this basis, the probable number of vibrating neutron stars of the type observed should be reduced by a further factor T_p/T_* where T_* is the mean total evolutionary time of neutron star candidates. With $T_* \sim 10^9$ yr, this would again reduce the number of possible candidates within 65 pc to unacceptably low levels. Similar arguments apply in the case of white dwarfs with corrections of order unity for the maximum possible energy and the expected number of stars. One is therefore in some difficulty to explain the observed number of sources of this type on the pulsating star hypothesis.

On the other hand, we run into very similar, though slightly less stringent, difficulties on the binary star hypothesis. Again assuming the source to be at 65 pc, our total energy requirements are increased by the ratio of orbital period to pulse duration and reduced by the amplification factor and, if the emission is coming from n_f smaller flare zones, by the factor $(r_f/n_f r_O)$. (If there were a correlation between flare activity and the position of the binary companion a further reduction would be possible.) Thus our energy requirements are probably of the same order of magnitude as those in the pulsating star theory, with the possibility of some reduction from the $(r_f/n_f r_O)$ factor. The expected number of pairs within 65 pc is thus likewise reduced to unacceptable levels.

The problem of energy supply and reasonable lifetimes thus seems insuperable unless the total emission rate at 65 pc turns out to be a considerable over-estimate. Otherwise only a harder core pressure than that from neutron degeneracy seems to offer any hope of resolving this difficulty. A possibility arises from the work by Hoyle and Narlikar[4] on the resistance to compression offered by the C-field. In this case the masses (to which there is no upper bound) are near their Schwarzschild radius. Clearly this topic requires a more detailed examination which is beyond the scope of this article. We merely note that to maintain the number density the mass cannot exceed $\sim 3\, M_\odot$ and the energy reserve not more than 10^{55} ergs. Thus even at the extreme, the lifetimes are only just comparable with T_* and the problem of expected probable numbers is barely resolved. We therefore feel that if either of these pictures is to prove correct the total emission rate at 65 pc must be reduced by at least $\sim T_*/T_p \sim 10^5$.

Whatever the figure for total emission rate turns out to be, we would, at this point, emphasize one important advantage of the binary star picture over the pulsating star hypothesis. In the latter, any energy taken from internal reserves causes a change in structure and hence in period on the time scale T_p. Thus even if the energy requirement is reduced so that $T_p \sim T_*$ the periods will cover a wide range, ensuring a small value for p_2 and hence of the expected number of sources. On the binary picture, however, these internal reserves and indeed energy stored in the region between the stars (in magnetic fields, for instance) could be utilized without altering the periods, provided the rest mass of the stars remains the same. Even at the estimated emission of $\sim 10^{47}$ ergs yr^{-1} this gives a maximum change in orbital period of 1 part in 10^7 yr^{-1}—still within the observational limits. We have, however, omitted any consideration of gravitational radiation throughout the analysis. We now examine this question in more detail.

Gravitational Radiation

There is still some controversy as to the precise situations in which gravitational waves are emitted. We follow the standard analysis of Landau and Lifshitz[9], who obtain for the characteristic time τ_B for changes in the binary orbit the expression

$$\tau_B \approx \frac{1}{128}\,\frac{c^5 l_{OD}^4}{G^3 M_1 M_2 (M_1+M_2)} = \frac{1}{128}\,\frac{c^5 (M_1+M_2)^{1/3}\,\omega^{-8/3}}{G^{5/3} M_1 M_2} \qquad (15)$$

Using the approximate values $M_1 = M_2 = 0.5\,M_\odot$ and $l_{OD} \sim 3\times 10^8$ cm as before, we obtain $\tau_B \approx 10^8$ s. By reducing one of the masses somewhat τ_B could be increased to at most $\sim 10^9$ s. This clearly implies a relative change of period far in excess of the observational limits and seems to exclude the binary star theory quite conclusively. Before proceeding, however, we would point out that the pulsating neutron star hypothesis also suffers in such an analysis.

For a pulsating star the characteristic decay time due to gravitational radiation is given[9,10] by

$$\tau_p \simeq \frac{5o\, c^5}{G M a^2 e^2\, \omega^4} \qquad (16)$$

where e is the ellipticity. As the loss rate is dominated by the highest harmonics present (16) could be an over-estimate. For a neutron star with a period of ~ 1 s we obtain[3] $M \sim 0.2\ M_\odot$, $a \sim 2\times 10^7$ cm, and thus $\tau_p \simeq 2\times 10^9/e^2$ s. Should neutron stars retain only ~ 1 per cent of the angular momentum of typical UMS stars, they would have marked ellipticity, $e \sim 0.1$, resulting in a decay time τ_p of at most $\sim 10^4$ years. (Similarly a white dwarf with solar angular momentum would have $\tau_p \sim 10^5$ years.) Such time scales are already incompatible with the observational data. There is, however, a suggestion due to Tsuruta and Cameron[11] that a strong magnetic field could remove sufficient angular momentum to reduce e to a negligible value. From their analysis, however, the required magnetic field would itself produce a substantial quadrupole moment. Thus, unless a fine balance exists in which first angular momentum and then magnetic fields are dissipated rapidly, the pulsating neutron star would lose its energy on an extremely short time-scale. The number of stars on the upper main sequence with low (effectively zero) angular momentum could produce the required type of neutron star but only with immensely reduced probability of observation. We feel that if the theory used here is correct the pulsating neutron star hypothesis can be excluded. Pulsating white dwarfs would seem to have the least difficulty concerning gravitational radiation, the associated time-scales always being $\gtrsim \tau_B$. Even in this case, however, one would expect changes in period on a time-scale of $\sim 10^{12}$ s (because most of these stars should be in rapid rotation even if on the main sequence they possessed only the solar angular momentum). This should also have been detected with the present observational data.

Both the binary star and the pulsating star models seem to succumb under the problem of gravitational radiation. On the other hand, our model appears to satisfy a number of other observational requirements in a rather natural way. If observations continue to support the binary star picture, and if general relativity is fundamentally correct, there seem to be two possible ways to resolve the gravitational radiation difficulty.

First, it may be that freely falling particles (binary stars, for example) do not radiate gravitational energy according to general relativity. This possibility has been urged by Bondi[12], who found that time dependent systems without "news" (that is, radiation of energy) can exist. The physical interpretation of his solutions remains controversial but, in view of the recent observations of rapidly pulsing radio sources and their otherwise plausible interpretation as binary stars, it is important that Bondi's suggestion be investigated in detail. We note, however, that this would not resolve the gravitational radiation problem in the case of pulsating neutron stars because the mass in these bodies is not in free fall.

The second possibility is that quantization effects become important in fairly high fields. The gravitational radiation difficulty is similar to that which faced spectroscopy before the Bohr theory. While physicists have long recognized the desirability of quantizing general relativity, no generally acceptable scheme has been proposed. To some extent, this failure may be due to lack of experimental or observational guidance for strong field situations. If our interpretation of these radio sources is correct, the remarkable constancy of the orbital period leads one to suspect some sort of quantization mechanism, that is, radiation free orbits, possibly arising as eigensolutions in the strong field (non-linear) equations. It may be significant that $v/c \approx 1/100 \approx \alpha$ where α is the electromagnetic fine structure constant. Could the observations be hinting that the usual strong field quantization condition $GM/rc^2 \approx 1$ is unrealistic and that $GM/rc^2 \approx \alpha$ is more relevant? We cannot pursue the matter further here, but it seems possible that once again astronomy may be able to provide a laboratory for testing consequences of the general theory of relativity, but this time in strong fields.

Predictions of the Binary Theory

The detailed consequences of our suggestion are now being evaluated. At the present stage, we are able to make some general predictions (applicable to neutron star pairs) which may act as further tests of the proposal.

(*a*) *For a single pulse arising from a homogeneous source region.* (i) The times of onset and disappearance should be the same at each frequency for measurements between given amplification levels. (ii) The duration of a pulse $\lesssim 2\times 10^{-2}\,T$, where T is the time interval between repeated pulses (that is, ~ 1.3 s in the present case). (iii) The *amplification* should be the same at all frequencies. It should be noted that in applying (i)–(iii) due allowance must be made for the residual signal level, which at some frequencies may swamp the amplified signal and cause spurious variations in the predicted temporal coincidences.

(*b*) *For multiple pulses.* In general, the original, unamplified signal may have two different components coming from (i) the whole surface and (ii) flare activity in concentrated regions. Both could be time varying. They should produce an observed signal as follows. (i) A general rise in the entire signal by a modest amount $\lesssim 17$ (cf. section 3) lasting at the lowest amplification levels for $\sim 2\times 10^{-2}\,T$ s. (ii) Sharply peaked signals with maximum amplification factors which may be $\gtrsim 17$ and with widths correspondingly narrower.

(*c*) The integrated unamplified signal received in time T should be comparable to the energy received in each pulse; thus the basic source should be detectable. However, we understand, that this test is quite difficult because of confusion with other, non-pulsing, sources in the area. One would expect to have similar difficulties in detecting the remaining $\sim 4 \times 10^3$ pairs within 65 pc which have alignments unsuitable for amplification

(*d*) If a source can be identified optically, then its light variations should either show sharp bursts similar to those observed at radio frequencies, or no amplification at all It should not show smooth light variations as one might expect from a pulsating star

(*e*) If the radio signals are short compared with the interval between them, as in the present case, an optical spectrum should not show classical white dwarf features Although neutron star spectra are at present unknown one might expect them to exhibit fairly featureless optical continua Should this be found, it might prove worthwhile to reinvestigate the nature of objects with such spectra, hitherto supposed to be a sub-set of the white dwarfs

We thank Professor F Hoyle, Dr D W Sciama, Professor Martin Ryle and Dr A Hewish for helpful discussions One of us (W C S) carried out this work during tenure of an NSF Pre-doctoral Fellowship and a Jesus College, Cambridge, research fellowship Two authors (J F and P A S) were in receipt of William Stone research fellowships at Peterhouse, Cambridge

Note added in proof Since this article was prepared, further observations have been reported by Ryle and Bailey[13] and Davies, Horton, Lyne, Rickett and Smith[14] Ryle and Bailey's provisional identification of the source with a blue star-like image of $\sim 18^m$ clearly offers the possibility of testing predictions (*d*) and (*e*) above The results of Davies *et al*, in particular the simultaneous onset of emission at all observed frequencies, and the appearance of multiple-pulsing with three or more single pulses per complete pulse, strongly support the binary view put forward in this paper Further observations of individual pulse shapes at several frequencies could distinguish between a pulsating theory in which plasma oscillations (Ryle and Bailey) produce radio bursts and the binary theory Frequency dependent collisional damping with a time constant $\alpha\nu^{-2}$ could produce substantially different pulse widths at different frequencies A ν^{-2} width-dependence would not be so easily explained on the binary hypothesis

Possible Model for a Rapidly Pulsating Radio Source

by

JEREMIAH OSTRIKER

Princeton University Observatory,
Princeton, New Jersey

The pulsating radio signals may come from active regions on rapidly rotating white dwarf stars This accounts for some aspects of the periodicity of the signals which are difficult to explain if the sources are pulsating stars.

RECENTLY, the Cambridge radio astronomy group has described observations of a rapidly pulsating radio source[1] Their observations can be summarized as follows (*a*) The signal observed at 81 5 MHz has a period of 1 337 s, the phase being constant to one part in 10^7 The amplitude, however, varies irregularly, the signal appearing and disappearing for periods of a few minutes Each pulse has a length of $\sim 0\ 3$ s (*b*) From the absence of proper motion and a consideration of the dispersive effects of transmission through the interstellar plasma the distance to the source is limited to the range 10^3 AU $< d <$ 65 pc (*c*) Variations of phase can be accounted for by the Earth's orbital motion without the need for additional correction for the motion of the source (*d*) No visible object brighter than twelfth magnitude is apparent in the radio error rectangle (*e*) From the signal width and rate of sweep the source size must be smaller than $4\ 8 \times 10^8$ cm

The authors[1] tentatively suggested that the radio signals come from a pulsating neutron star or white dwarf The calculations of Meltzer and Thorne[2], however, show that stable (as opposed to unstable or metastable) neutron stars have central densities in the range $2\ 7 \times 10^{13} \leqslant \rho_c \leqslant 6\ 0 \times 10^{15}$ and fundamental modes of radial oscillation with periods in the range $5 \times 10^{-2} \geqslant T \geqslant 8 \times 10^{-4}$ Overtones of the fundamental modes have shorter periods still, so pulsating neutron stars seem to be an unlikely origin for the radio signals On the other hand, white dwarf radial oscillations always have periods[2] exceeding 8 s The equilibrium models, however, assume that the nuclear matter of the white dwarfs has been catalysed to the end point of thermonuclear evolution A more realistic equation of state derived by Salpeter[3] produces equilibrium models of higher density[4] and consequently shorter period In any case, observations (*a*) are very difficult to understand if the source is a pulsating star With the large energy that would be stored in a stellar pulsation it is not easy to see how the amplitude could be so variable. If surface pulsations are adopted it is easier to understand how the signal could appear and disappear at irregular intervals but very difficult to understand why the phase should be constant over successive reappearances Because it has been suggested that the radio source may be associated with a planet, it is perhaps worth noting that from (*b*) and (*d*) the associated star must be faint (fainter than eighth magnitude) but is likely to be further from the planet than 1 AU (*c*)

We require an intrinsically faint (*b, d*), small (*e*) star having a natural period of ~ 1 s (*a*) For the reasons mentioned it seems unlikely that the periodic behaviour is associated with a pulsation period Periodic behaviour is also found astronomically in two other cases, orbital motion and rotation, both of which can cause periodic variations in apparent magnitude

We can estimate the shortest possible period for orbiting ordinary stars if we consider a congruent pair of white dwarfs which are assumed to be undistorted by tidal or rotational forces and which are in a grazing circular orbit about one another For stars of mass M and radius R the period P must satisfy the inequality

$$P > 4\pi\left(\frac{R^3}{GM}\right)^{1/2} > 17\,\mathrm{s}$$

The numerical result is obtained by using the mass and radius ($1\ 396\ M_\odot$, $0\ 216 \times 10^{-2}\ R_\odot$) derived[4] for a carbon white dwarf on the verge of implosion due to inverse β

Table 1 MODEL OF A RAPIDLY ROTATING WHITE DWARF

P_0	1.25 s
$P_{\frac{1}{2}}$	1.61 s
P_1	6.50 s

decay. For a pair of neutron stars the desired orbital period can be obtained, but gravitational radiation caused by the varying quadrupole moment[5] would produce a continuous rate of frequency shift equal to

$$\left(\frac{\Delta\omega}{\omega}\right)=\frac{96}{5}\,\frac{\varepsilon}{(1+\varepsilon)^{1/3}}\,\frac{(GM)^{5/3}}{c^5}\,\omega^{8/3}\Delta t$$

Stars having masses M and εM and circular orbits about their mutual centre of mass have been assumed. For stable neutron stars, $M>0.18\ M_\odot$, $4.0>\varepsilon>0.25$, so that the expected change in frequency would be

$$\frac{\Delta\omega}{\omega}>7\times10^{-5}\ \text{day}^{-1}$$

a possibility which can be ruled out by the observations.

Finally, we consider rotation. The angular velocity at the equator of a rapidly rotating, condensed, star can be estimated by the Keplerian relation

$$\Omega=\left(\frac{GM}{R^3}\right)^{1/2}$$

which, if the period ($P=2\pi/\Omega$) is to be the order of 1 s, gives a "density" ($3M/4\pi R^3$) of the order of 10^8 g/cm^{-3}. This density is characteristic of the matter in the more massive white dwarf stars. Recently[6,7] various sequences of models of rapidly, differentially rotating white dwarfs have been constructed with masses both above and below the mass limit[8] ($1.44\ M_\odot$) for non-rotating white dwarfs. The models with rotation periods as short as 1 s have masses in the range 1–3 $M_\odot$. In Table 1 we summarize the properties of a $2.26\ M_\odot$ model with angular momentum $J=3.46\times10^5$ g cm^2 s^{-1} (characteristic of the main-sequence star having the same mass) and the same angular momentum distribution as in a uniformly rotating uniform sphere.

In Table 1, R is the radius, P the period of rotation, ρ_c the central density and E the binding energy. The subscripts "0", "½" or "1" refer to quantities measured on a cylinder containing that fraction of the mass, subscripts "e" and "p" refer to the equator and the pole. We note, in connexion with observation (e), that the star is smaller than 5×10^8 cm. This very rapidly rotating star ($v\sim5{,}000$ km s^{-1}) might be expected to be in danger of fission caused by an instability to a nonaxisymmetric mode. The lowest ($m=1$, 2) modes have been checked by Tassoul and myself and the star is found to be stable in the absence of viscosity but unstable, with an e-folding time of $\sim10^{10}$ yr, when viscous forces are included, that is, the model is stable.

We can imagine an active region on such a star emitting radiation similar to type II or III solar bursts, each burst lasting the order of a few minutes. During this time radio energy is emitted in the direction of the Earth as a set of pulses, one per period, the period being characteristic of the latitude of the active region. For the time of emission to be as short as inferred from the observations (0.016 s) it is necessary that the radiation be emitted in a cone of width $\sim1°$. A subsequent burst from the same active region would appear on the observer's record as a new set of pulses with amplitude unrelated to the first set but exactly in phase with them. If active regions appear at other points at the same latitude, sudden phase shifts would be observed caused by differential rotation; a shift to active regions at other latitudes would lead to changes in both phase and period.

The details of the model presented here are clearly very tentative. The major point to be made is that rotation provides perhaps the best explanation for the periodicity of the new radio sources, and that rapidly rotating white dwarfs have rotation periods in the experimentally observed range.

Nuclear Uptake of Exogenous DNA by Mammalian Cells in Culture

by
A. B. ROBINS
D. M. TAYLOR

Belmont, Sutton, Surrey

The uptake of exogenous DNA by mammalian cells in culture may amount to 5 per cent of the host cell complement. This material is found within the nucleus, but most of it is not incorporated into the chromosomes.

It is well established that mammalian cells, both *in vivo* and *in vitro*, can take up DNA in a macromolecular form, and this phenomenon has been critically reviewed by Ledoux who has emphasized its generality and importance[1]. It has been assumed by many workers, however, without any experimental evidence to support their assumptions, that the exogenous DNA which is taken up in this way becomes incorporated into the chromosomes. The possibility that exogenous DNA can be exchanged with chromosomal DNA in a manner analogous to that which occurs in bacterial transformation is obviously important from a number of viewpoints. For example, it has been claimed that exogenous DNA is effective in the repair of damaged material in the cell[2–5], that it can induce tumours[6] or lead to tumour regression[7], and these effects have sometimes been ascribed to such an exchange. A hypothesis of carcinogenesis involving freely circulating DNA has already been proposed[8]. Furthermore, the specificity of ^{3}H-thymidine as a label for cells in DNA synthesis would need to be re-examined for experiments in which measure-

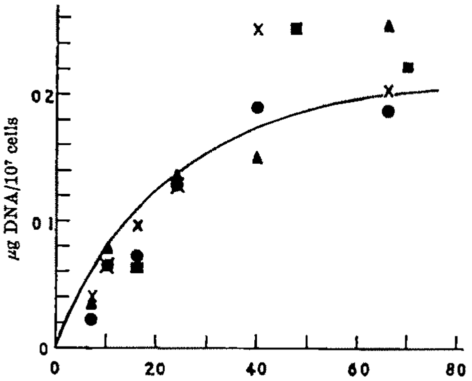

Fig. 1. Incorporation of ^{14}C-DNA by cells in exponential growth as a function of time expressed as ■, whole DNA, ●, adenine, ▲, guanine, ×, thymine Solid curve expresses the function incorporation = 0 21 $(1-2^{-t/15})$

ments of the cell labelling index were to be made at intervals greater than a few hours after the administration of the tracer

In this article, a distinction will be made between the uptake of DNA by a cell, and its true, chromosomal, incorporation The experiments were designed to examine the possibility of a true incorporation, using cultures of lymphoma cells, and exogenous DNA labelled with carbon-14, isolated from the same strain of cells The amount of DNA which had entered the nucleus was measured and then an estimate was made of the maximum amount of this material which could be regarded as having been incorporated It has been found that this amount is very small, and may be insignificant

Murine lymphoma cells (*L5178Y*) were labelled during exponential growth with 0 25 μCi of ^{14}C-formate/ml of medium at 37° C for 65 h, the final cell population being 5×10^5 cells/ml The medium used throughout these experiments was the full medium developed by Fischer[9] The cells were washed free of active medium with isotonic saline, and shaken in 2 M NaCl for 10 min One-tenth the volume of 10 per cent dodecyl sulphate was added, and the whole shaken overnight After centrifugation at 3,000 r p m the DNA was precipitated from the clear solution by gently stirring in two volumes of ethanol It was redissolved immediately in a minimal amount of 10^{-3} M NaCl and subjected to ribonuclease digestion (20 μg of ribonuclease/ml for 4 h), after which the solution was made 1 M in NaCl and the DNA again precipitated with ethanol The resultant DNA contained less than 5 per cent protein, and had a viscosity-average molecular weight of 2×10^7 An aliquot of the nucleic acid was hydrolysed with 90 per cent formic acid for 45 min at 165° C, and electrophoresed on Whatman *3MM* paper for 9 h at 7 V/cm in pyridine-acetate buffer, *p*H 3 5 Bases were located under ultraviolet light, eluted with 0 1 N HCl, and measured spectrophotometrically The carbon-14 activity was determined in a liquid scintillation counter ('Tracerlab *LSC*-30'), with an efficiency of 90 per cent In later experiments in which larger volumes of aqueous phase had to be employed because of their low radioactivity, an emulsion scintillator was used This consisted of 70 per cent Nuclear Enterprises *NE* 214 and 30 per cent 'Triton *X*-100', the efficiency in this case was 75–80 per cent In the conditions which have been described, the carbon-14 activity of the isolated DNA was between 2 1 and 2 3 μCi/μg of DNA

To study the incorporation of homologous DNA by cells, two experimental procedures were followed (*a*) prolonged incorporation at a low DNA concentration during exponential growth of the cells, and (*b*) a 30 min "pulse" incorporation at much higher DNA concentrations[10] With procedure (*a*), a concentration of approximately 1 μg ^{14}C-DNA, prepared as outlined, was present in each ml of culture for varying lengths of time up to 70 h Under procedure (*b*), concentrations of DNA were varied from 1 to 400 μg/ml of suspension, the cell concentration in this case being standardized at 2×10^7 cells/ml at 37° C Following both types of incorporation, collected cells were washed four times with 0 08 M iodoacetate, 0 14 M NaCl, *p*H 7, to remove much of the adhering DNA[10] Nuclei were isolated at 4° C by suspending in Creasey–Stocken medium[11] and performing 70–80 hand reciprocations in a Teflon–glass homogenizer size A. After a centrifugation at 1,000 r p m, the nuclei were pelleted by centrifugation at 40,000*g* in 2 2 M sucrose The DNA was extracted and analysed in an identical manner to that described for the original "donor" DNA

The uptake of ^{14}C-DNA in condition (*a*) is shown in Fig 1 as a function of the time allowed for uptake Although the results are expressed in μg of DNA/10^7 cells, these have been calculated from the separate values for the three bases guanine, adenine and thymine The agreement between these values suggests that macromolecular uptake is more likely than a breakdown to, and re-incorporation of, precursors Further support for this was found in the fact that the uptake of a nucleotide mixture (produced by enzymatic hydrolysis of ^{14}C-DNA) was 3 μg of DNA per 10^7 cells for adenylate and guanylate, and 20 μg of DNA for thymidylate after 65 h—that is, a factor of 15 to 100 times greater than the values in Fig 1 The curve drawn in Fig 1 was calculated by assuming that cells which are synthesizing DNA before division derive a constant fraction of this material from ^{14}C-DNA in the medium The incorporation per cell is given by $I = k\,(1-2^{-t/d})$, where the doubling time, *d*, is 15 h and *t* is the time of exposure of cells to DNA within the medium A value of $t = 70$ h was used to approximate to the condition $t = \infty$ and to calculate *k* The data of Fig 1 fit this relation, although this does not, of course, prove the original premise on which the curve was based

The uptake of ^{14}C-DNA under condition (*b*) is shown in Fig 2 as a function of the DNA concentration Again the uptake is expressed as μg of DNA/10^7 cells, the points representing values for the individual bases The specific activity ratios for (guanine adenine) and (thymine · adenine) for the donor DNA were $0 99 \pm 0 06$ (*S D*) and $0 55 \pm 0 10$, respectively, for fourteen preparations The corresponding values for the same ratios in seventeen preparations of host DNA (after uptake) were $1 07 \pm 0 21$, and $0 56 \pm 0 10$, respectively Such constancy of the ratios before and after incorporation suggests that the DNA has retained its macromolecular form[10] The incorporation of a nucleotide mixture such as that used under condition (*a*) was also investigated under "pulse" conditions, and here the uptake was between five and ten-fold lower for the nucleotide mixture than for intact DNA under the same conditions This suggests that the incorporation of intact DNA follows a different pattern from that of the con-

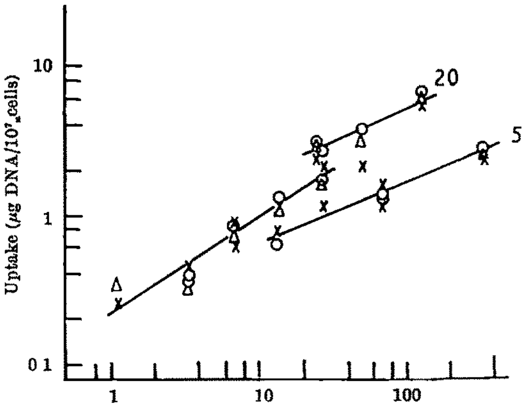

Fig 2 Uptake of ^{14}C-DNA by cells in 30 min at 37° C, as a function of DNA concentration, expressed as ○, adenine, △, guanine, ×, thymine

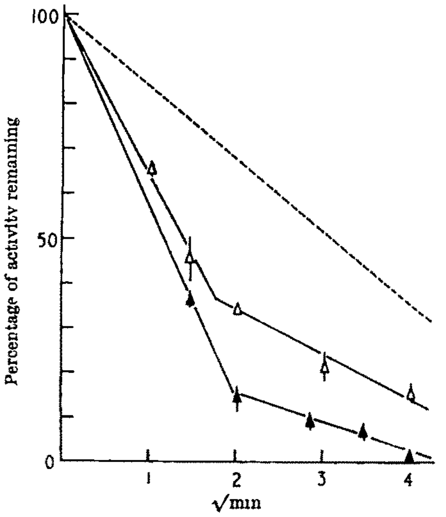

Fig. 3. Percentage original total carbon-14 activity within nuclei which remained after t min of treatment with DNase, as a function of $t^{1/2}$. Concentration DNase 35 μg ml⁻¹. Uppermost line is the regression line for four experiments on nuclei labelled with ^{14}C-formate. △▲, Two experiments with nuclei labelled with ^{14}C-DNA during 30 min "pulse".

stituent nucleotides, a result which has also been reported by Ledoux[12].

The three regression lines in Fig. 2 express results from experiments in which the cell population contained different proportions of "dead" cells, that is, cells which under the phase-contrast microscope were opaque. The enhanced uptake which seems to occur when non-viable cells are present would suggest that some, at least, of the uptake does not depend on the metabolism of the cell. When similar experiments to those of Fig. 2 were carried out in the presence of inhibitors, only a slight effect upon uptake was seen. For example, 100 μg of barbiturate/ml. of cell suspension containing 30 μg of DNA/ml reduced the uptake from 5.0 ± 0.3 to 4.1 ± 0.1 μg of DNA/10^7 cells. The corresponding effect in the presence of 100 μg of oligomycin/ml was an increase to 5.8 ± 0.3 μg of DNA/10^7 cells. In the absence of inhibitors but at 2° C instead of 37° C the uptake was decreased to 3.0 ± 0.5 μg DNA/10^7 cells. Evidently the uptake of DNA is not greatly affected by the inhibition of oxidative phosphorylation and active transport processes in the first two cases.

There are reports of DNA incorporation similar to that described here in other biological systems, and it has been demonstrated that the DNA probably retains its macromolecular form[12-14]. In all such instances, the chief difficulty is to show whether or not the material is truly incorporated into the chromosome[15]. In order to resolve this uncertainty, two lines of approach can be followed. Either the exogenous DNA can be separated from the host cell DNA after the incorporation, or traces of "donor" DNA can be made recognizable within the host cell complement. It is experimentally very difficult to realize the first objective, but one indirect method was attempted. After the extraction of nuclei from cells which had taken up ^{14}C-DNA, these were subjected to the action of deoxyribonuclease I in a manner identical to that described elsewhere[16]. The result of such treatment is shown in Fig. 3, and it is apparent that there is a sharp initial fall in the activity relative to the control value, after which a more gradual loss in activity follows. This slower rate of activity loss is roughly parallel to that which occurs when control nuclei, labelled chromosomally with ^{14}C-formate during exponential growth, are similarly treated with enzymes. Possibly there are two different modes of retention of the DNA, namely a temporary and a more permanent fixation[13].

The alternative approach, namely that of recognition of donor DNA, was followed by the use of the density marker 5-bromouracil. Cells were grown in the presence of ^{14}C-formate to yield ^{14}C-DNA, but during the last 24 h of exponential growth, 5-bromodeoxyuridine was added to a concentration of 6×10^{-6} M. After extraction the DNA was hydrolysed in the usual manner, and the bases separated by two-dimensional thin-layer chromatography on cellulose[17]. The specific activity of the bases was found to be identical to that observed previously, and the replacement of thymidine by 5-bromouracil was between 45 and 50 per cent. Incorporation experiments in "pulse" condition (*b*) showed that the BU-DNA was taken up by cells to the same extent as unsubstituted DNA. Samples of donor BU-DNA, and of host cell DNA after incorporation were subjected to density-gradient centrifugation in caesium chloride, and in three experiments out of a total of five a physical mixture of BU-DNA and unlabelled, unsubstituted DNA was also employed for comparison.

In each experiment between 100 and 150 μg of DNA in 0.3 ml of water were added to 3 ml of caesium chloride solution (60 per cent w/w British Drug Houses, Ltd.) in a 5 ml polypropylene tube and covered with 1 ml. liquid paraffin. Centrifugation was carried out for 65 h at 29,000 r.p.m. and ambient temperature in the swinging bucket rotor of an MSE 'Superspeed 40' centrifuge. Tubes were pierced subsequently and the gradient fractionated into 75–80, five-drop samples which were diluted by the addition of 0.7 ml of water. Optical densities were measured in thick-walled 1 cm cells in a spectrophotometer (Cary 15)

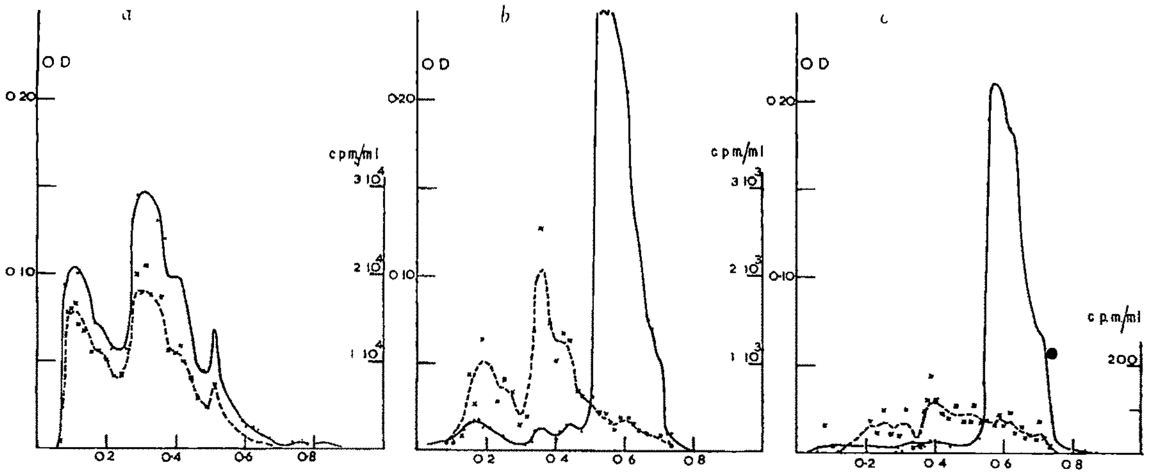

Fig. 4. Optical density, and activity profiles of carbon-14 after caesium chloride centrifugation of (*a*) donor BU-^{14}C-DNA, (*b*) donor DNA + unsubstituted, unlabelled DNA, (*c*) host cell DNA after incorporation (Table 1, run 5). (●) optical density, (×) carbon-14 activity.

Table 1 SPECIFIC ACTIVITIES AND AMOUNT OF BU-DNA TAKEN UP BY LYMPHOMA CELLS

Run	Specific activity under "light" peak (c p m /μg DNA) Calculated	 Observed	 Difference	Uptake BU-DNA / Host cell DNA %	Bound BU-DNA / Host cell DNA %
1	14 7±1 0	21 2±2 5	6 5±1 4	5 2	0 31±0 07
2	26 6±3 6	32 8±3 5	6 2±2 5	5 2	0 29±0 12
3	Approx 6 5	10 0±1 7	3 5	4 3	0 11
4	9 3±0 7	7 4±1 7	−1 9±0 9	4 3	−0 10±0 04
5	3 1	5 0±4 5	1 9	1 1	0 06

and aliquots counted for carbon-14 activity The results of one run in which "donor", "incorporated" and "mixture" DNA samples were centrifuged are shown in Fig 4 The BU-DNA peaks are well separated from each other and from the "light" DNA, although in different experiments the proportion of the DNA in the peaks was found to vary For example, in two experiments, 60 to 65 per cent of the donor DNA was found to be labelled in both strands whereas, in the other samples, 60 per cent was found to be labelled in one strand This was probably a reflexion of the age of the culture medium and other factors which affect the growth rate of the cells

In Fig 4, a third small peak can be seen in the donor BU-substituted DNA which corresponds to a proportion of the DNA which had escaped BU substitution In the experiment of Fig 4, the proportion of this peak was 7 5 per cent but the proportion varied for different preparations This unsubstituted material leads to contamination of the host cell DNA with carbon-14 activity which, although originating in the donor material, will run with the host material, and allowance must be made for this In practice, the average specific activities of the host cell DNA in the neighbourhood of the optical density peak were compared with an "estimated specific activity" calculated from that of the donor DNA, the amount of incorporation and the proportion of non-BU-substituted DNA (Table 1) In four cases, the experimental values are greater, and in one case less, than the calculated values The difference between observed and calculated values may be taken as the specific activity within the host cell which has originated from the donor DNA and which is sufficiently tightly bound, or incorporated, to move with it on centrifugation In the last column of Table 1, this difference is expressed in terms of the total donor DNA which it represents, as a percentage of the host cell material. The values are in all cases less than 0 3 per cent and therefore it is very doubtful if any chromosomal incorporation has occurred in these conditions

To summarize, it has been demonstrated that although the uptake of exogenous DNA by cells may amount to as much as 5 per cent of the host cell complement, and that this material is found within the nucleus, most of it is not chromosomally incorporated. This fact must also exclude the possibility of breakdown of the DNA to precursors and re-utilization of these. Two unsettled questions which remain are whether the large amount of DNA taken up into the nucleus performs any function, and whether even the extremely small amount of true incorporation—if real—could have genetic consequences Some preliminary experiments have been performed to investigate this latter possibility, but so far without any positive proof

We thank Miss P S Bond for expert assistance with the experimental work and Professor L F Lamerton for helpful guidance throughout

Effect of Dehydration on Bacterial Recombination

by

S J WEBB

Department of Bacteriology,
University of Saskatchewan,
Saskatoon, Saskatchewan, Canada

When water is removed from DNA by semi-dehydration there is a pronounced effect on its *in vivo* activity, and the effect may be more severe in some regions of the chromosome than others. The effects of dehydration on the ability of cells to take part in recombination have been studied in three non-lysogenic strains of *Escherichia coli K12*

Two principal factors seem to be involved in the mechanisms by which bacterial cells lose their viability when they are held in aerosols at various levels of humidity (RH): first, the removal and reorientation of water molecules which are bound to cell macromolecules, resulting in the loss of the structural integrity of the latter[1]; and second, the oxidation by oxygen of cell components leading to the possible destruction of flavin-linked enzymes[2,3] The former type of damage occurs when bacterial cells are held at RH levels ranging from 80–40 per cent and the latter type when cells are held at RH values below 40 per cent[2,3].

Experiments designed to determine the type of macromolecules which are affected or destroyed by the complete or partial loss of their bound water have shown that the loss of water leads to (*a*) the inability of cells to manufacture new protein[1,4,5], (*b*) the destruction of free and intracellular DNA bacteriophages[1,6,7]; (*c*) the production of mutant cells[8,9], and (*d*) the induction of prophages within lysogenic bacterial cells[10,11] The inability of some cells to manufacture new protein after periods of dehydration has led some investigators to suggest that the activity of cellular RNA is impaired as a result of structural alterations in RNA molecules when these lose their bound water Evidence of this has been presented by DeJong[12], who has shown that certain RNA viruses lose their infectivity as a result of partial dehydration Other researchers consider that a failure in *s*RNA synthesis leads to lack of manufacture of protein and cell death[3]. The mutagenic action of partial dehydration and the destruction of free and intracellular DNA phages, however, indicate that the biological activity of cell DNA is affected by the loss of its bound water Because the structure of isolated DNA is known to rely on the presence of correctly placed water molecules[13,14], the failure of *s*RNA synthesis is therefore reasoned to be the result of DNA damage

Because all attempts to demonstrate damage to enzymes existing in cells before they are dehydrated have failed, the induction of lambda prophages by desiccation seems to be the result of a direct effect of dehydration on DNA The removal of bound water has therefore been suggested to separate prophage DNA from host DNA in accordance with a mechanism of prophage induction suggested by some workers The destruction of a protein normally able to repress the maturation of the prophage is, however, currently the popular concept of induction, and if this repressor protein is susceptible to damage by very small doses of radiation, then it is conceivable that it is also susceptible to damage by dehydration

In many respects recombination following the transfer of DNA from one cell to another during conjugation resembles the incorporation of viral DNA into the genome of a susceptible host cell Hayes[15] has likened the transfer of the fertility factor *F* to lysogenation and moreover has shown that the irradiation of donor cells with small doses of radiation vastly increases the number of recombinants obtained Because at present there seems to be no function for repressor protein in recombination phenomena, it seemed pertinent to undertake an investigation into the effects of partial dehydration on the ability of cells to take part in recombination

The three non-lysogenic strains of *Escherichia coli K*12 used in the studies were (1) NCIB 9481 $F^+(Met^-)$, (2) NCIB 9482 $F^-(L^-T^-B_1^-Lac^-)$ and *HfrH* (Met^-), kindly supplied by Dr Ashwood-Smith and modified to non-lysogeny The cells were grown at 37° C for 24 h in brain–heart infusion broth, collected by centrifugation, resuspended to form a cell concentration of approximately 5×10^8 cells/ml in fresh media and reincubated for 4 h After this incubation the cells were washed in distilled water, and resuspended to give a cell concentration of approximately 1×10^{10} cells/ml in distilled water or 5 per cent w/v myo-inositol The cells in these suspensions were atomized into a rotating stainless steel aerosol drum in which the relative humidity had been pre-set to a desired level Immediately after and at subsequent intervals of time, samples of the airborne cells were collected in liquid impingers operating at 12 l /min and containing 8 ml of 1 per cent glucose in 0 85 per cent NaCl (saline) Hayes[15] has shown that in order to obtain an increase in the number of recombinant cells when the donor strain is irradiated with small doses of ultraviolet light, the cells should be incubated in nutrient broth for 60 min before they are mixed with the recipient strain To each of the samples collected from the aerosol 3 ml of double strength nutrient broth (NB) was therefore added and the cells were incubated at 37° C for 60 min Following this, two 1 ml aliquots of the cells were removed, incubated for 45 min at 37° C, washed twice in distilled water and one was plated on minimal salt medium to check for reverse mutation The other was serially diluted in NB and

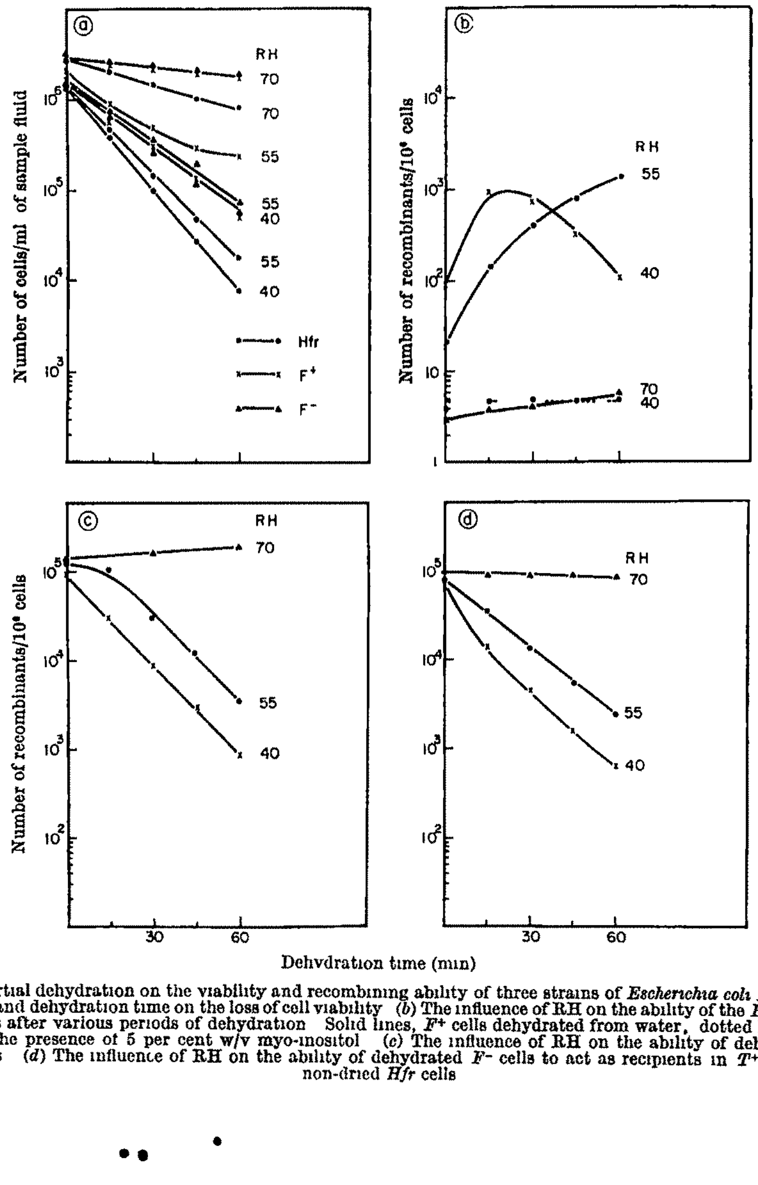

Fig 1 The effect of partial dehydration on the viability and recombining ability of three strains of *Escherichia coli K*12 (*a*) The influence of relative humidity (RH) and dehydration time on the loss of cell viability (*b*) The influence of RH on the ability of the F^+ strain to act as a donor in T^+L^+ recombinations after various periods of dehydration Solid lines, F^+ cells dehydrated from water, dotted line, F^+ cells dehydrated at 40 per cent RH in the presence of 5 per cent w/v myo-inositol (*c*) The influence of RH on the ability of dehydrated *Hfr* cells to act in T^+L^+ recombinations (*d*) The influence of RH on the ability of dehydrated F^- cells to act as recipients in T^+L^+ recombinations with non-dried *Hfr* cells

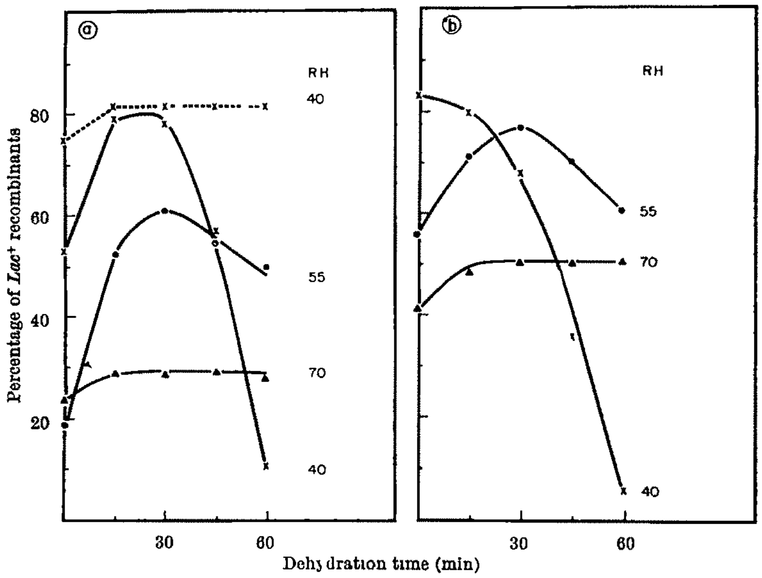

Fig. 2. The effect of partial dehydration on the percentage of T^+L^+ recombinants possessing the Lac^+ character. (*a*) The influence of relative humidity (RH) on the percentage of T^+L^+ recombinants possessing the Lac^+ character after crosses between semi-dried F^+ cells and non-dried F^- recipients. Solid lines, F^+ cells not exposed to lactose prior to drying; dotted line, F^+ cells exposed to lactose before drying. (*b*) The influence of RH on the percentage of T^+L^+ recombinants possessing the Lac^+ character after crosses between semi-dried *Hfr* cells and non-dried F^- recipient cells.

0.2 ml of each dilution was plated onto nutrient agar for viable counts. The cells in the remaining portion of the sample were concentrated by centrifugation and recipient or donor cells from a 6 h culture in NB were added so that the proportion of donor : recipient cells was approximately 1–2 × 10^7/ml, respectively. The mixed cells were incubated at 37° C for 45 min, washed twice in distilled water, resuspended in 5 ml of water, serially diluted and 0.5 ml of each dilution plated onto a minimal medium (MM) consisting of the following/l: NH_4Cl, 5 g, Na_2SO_4, 1 g, K_2HPO_4, 3 g, KH_2PO_4, 1 g, $MgSO_4$, 100 mg, glucose, 5 g; asparagine, 1.5 g, thiamine, 2 mg. The nutrient agar plates used for viability counts were incubated at 37° C for 24 h, after which time the colonies were scored and the MM plates were incubated for 48 h at 37° C before recombinant colonies were counted. To test for T^+L^+ Lac^+ recombinants the T^+L^+ recombinant colonies were picked off and plated on MM containing lactose instead of glucose and EMB agar.

In initial experiments with crosses of non-aerosolized cells, the $F^+ \times F^-$ cross produced from three–six T^+L^+ recombinants/10^6 donor cells, of which approximately 20 per cent received the Lac^+ marker. In the *Hfr* × F^- cross, 16–17 per cent of the donor cells produced recombinants, of which from 40–43 per cent possessed the three markers studied. Back mutation to prototrophy of the recipient cell was not observed and approximately one prototroph/10^7 donor cells occurred in both *Hfr* and F^+ strains. With *Hfr* and F^+ cells held in aerosols of 40 or 55 per cent relative humidity, the number of prototrophic colonies produced by reverse mutation increased to values between 20 and 30/10^7 cells recovered. In view of the large number of recombinants obtained with aerosolized *Hfr* and F^+ cells, however, this reverse mutation was ignored in the interpretation of the experimental results described here.

The recovery of cells after various periods of time of storage in air at the three relative humidities selected is shown in Fig. 1*a* for the three strains of organisms used. The *Hfr* strain was more susceptible to partial dehydration at the three relative humidity levels than either of the other two strains. No significant changes in the number of T^+L^+ recombinants were observed when the F^+ donor cells were held in aerosols at 70 per cent relative humidity. When they were held at 55 or 40 per cent relative humidity, however, an increase in the number of T^+L^+ prototrophs occurred even with cells collected immediately after their aerosolization. It takes 5 min to generate the aerosol, so this increase in recombinants seems to be caused by processes occurring in the cells during the first 5 min of partial dehydration at 55 or 40 per cent relative humidity. When the cells were held at 55 per cent relative humidity the number of T^+L^+ recombinants obtained steadily increased as the time of storage in the aerosol increased, until their numbers reached approximately 0.1 per cent at the end of the 60 min period studied. If the cells were stored at 40 per cent relative humidity, the number of recombinants obtained increased by more than a hundred-fold and reached a maximum number after 15 min of storage. Holding the cells for longer periods resulted in a drop in the number of recombinants obtained (Fig. 1*b*). The fact that the number of viable cells decreased posed a problem as to whether the results should be presented in terms of the number of recombinants/10^6 viable cells present in the initial samples collected from the aerosols, or the number of viable cells obtained in the samples collected at the various intervals of time.

For the sake of clarity it was decided to present them in both ways, and in Fig. 1 and Table 1 the former and latter methods have been used, respectively. If the two sets of data are compared, it can be seen that when the F^+ cell was held at 55 per cent RH, the number of recombinants obtained represented approximately 0.12 per cent of the viable cells present in the initial samples collected, or approximately 0.44 per cent of the viable cell number present in the 60 min sample. When the cells were held at 40 per cent relative humidity the percentage of viable cells donating DNA present in the sample at the time of collection increased during the first 45 min of storage, reaching a maximum value of 0.35 per cent, and decreased thereafter. These results suggest therefore that either a larger proportion of the surviving cells donate DNA to the recipient cells as the time of storage increases, or else some cells unable to form colonies are able to donate active DNA.

Based on the number of viable cells present in the initial sample, no increase in the number of recombinants was observed when the *Hfr* strain was subjected to periods of partial dehydration at 70 per cent RH, but when these cells were held at 40 and 55 per cent relative humidity the number of recombinants obtained decreased

Table 1 EFFECT OF SEMI-DEHYDRATION ON BACTERIAL RECOMBINATIONS

Cross	RH	Time of drying in air 0	15	30	45	60
F^+(D) × F^-	40	0.08*	0.13	0.27	0.35	0.31
	55	0.002	0.031	0.085	0.23	0.44
	70	0.0003	—	—	—	0.0005
Hfr(D) × F^-	40	7.2	7.8	9.1	10.3	8.4
	55	9.6	21.3	18.4	23.6	16.5
	70	11.3	18.6	17.4	21.2	24.3
Hfr × F^-(D)	40	8.3	2.1	1.5	1.2	0.96
	55	9.1	5.3	3.7	3.6	3.2
	70	11.2	9.6	12.3	12.1	8.4

Cells of *Escherichia coli K*12 were held at various levels of relative humidity for set periods of time and then mixed with suitable donor or recipient cells.

D, Semi-dried cell. RH, Relative humidity.

* Results expressed as percentage of viable semi-dried cells taking part in recombination.

rapidly with time (Fig. 1*c*). When based on the number of viable cells present at the time of sampling and recombinants obtained, however, the percentage of cells transferring DNA seemed to remain fairly constant. These results indicated that the ability of the *Hfr* cell to donate active DNA to the F^- cell decreased at approximately the same rate as its viability or ability to form colonies. Exposing the F^- cell to periods of partial dehydration resulted in a rapid decrease in the number of recombinants obtained when these cells were mated with non-dried *Hfr* cells. The rate at which the percentage of recombinants decreased seemed to be more rapid than the loss of F^- cell viability, particularly when the recipient cell was held at 40 per cent relative humidity (Fig. 1*d*, Table 1).

If the *Hfr*, F^+ or F^- cells were aerosolized from 5 per cent myo-inositol, none of the effects of partial dehydration were observed. These results are represented by the dotted line in Fig. 1. It seemed therefore that the presence of myo-inositol prevented both the increased ability of F^+ cell to donate its DNA and the decreased effectiveness of the F^- to receive it because of their partial dehydration in aerosols.

The percentage of T^+L^+ recombinants possessing the Lac^+ character is shown in Fig. 2. When *Hfr* or F^+ cells were held at 70 per cent relative humidity, the percentage of Lac^+ recombinants increased very slightly during the first 15–30 min and then remained constant. With the former strain of cell, between 42 and 48 per cent, and with the latter strain, between 24 and 27 per cent, of the recombinants were Lac^+, regardless of the holding time in the aerosol. The holding of the cells in aerosols of 55 per cent relative humidity, however, resulted in a substantial increase in the percentage of recombinant cells possessing the Lac^+ character. With the *Hfr* and F^+ cells, respectively, the percentage increased to 79 per cent and 53 per cent after a 30 min period of storage and then gradually decreased. When these cells were held at 40 per cent relative humidity, a difference in the behaviour of the two types of cell became evident. With the *Hfr* strain, 84 per cent of the recombinants obtained using the cells in the initial aerosol samples proved to be Lac^+ ones, but continued holding resulted in a rapid decrease in their numbers until, after 60 min, they represented less than 6 per cent of the T^+L^+ recombinants obtained. As a result of holding the F^+ cell at 40 per cent relative humidity, the percentage of Lac^+ recombinants increased from 55 per cent to 80 per cent during the first 15 min, remaining relatively constant during the next 15 min, and then fell during the remaining 30 min. These findings seemed to explain the permanent or temporary failure of many cells surviving semi-dehydration at 55–35 per cent RH to manufacture enzymes concerned in the metabolism of lactose.

From the results presented in Fig. 2, the Lac^+ locus seemed to be more susceptible to damage than the T^+L^+ loci. In the knowledge that cells exposed to lactose before they are dehydrated do not readily lose their ability to manufacture enzymes that metabolize lactose, the validity of the foregoing hypothesis was tested by examining the behaviour of F^+ cells grown in nutrient broth supplemented with 2 per cent lactose. When these cells were subjected to periods of semi-dryness in the aerosol, the percentage of Lac^+ recombinants subsequently obtained increased to about 80 per cent and then remained constant. The decrease observed with cells not exposed to lactose did not occur. This is shown by the dotted line in Fig. 2*a*. Thus it would seem that contact between the cell and lactose before the cell was dehydrated stabilizes the Lac^+ portion of the DNA against the destruction by dehydration.

The genetic implications of the results presented are not understood and will require much more experimentation for a reasonable explanation to be offered. From the standpoint of dehydration damage, however, the increase in the number of recombinants obtained when F^+ cells are dehydrated at 40 or 55 per cent RH and the prevention of this phenomenon by myo-inositol are remarkably similar to the effects of dehydration and inositol on the induction of lambda prophages. If prophage induction by dehydration results from the separation of phage DNA from host DNA, then the increase in recombinants seems to occur as a result of a more efficient transfer of F^+ donor DNA to the recipient cells as a result of some kind of DNA fragmentation. The involvement of permeability changes in this phenomenon seems to be ruled out because (*a*) dehydration and inositol both increase cell permeability, yet inositol will prevent the increase in recombinants; and (*b*) the efficiency of the recipient cell to receive DNA is decreased, not increased, by dehydration. The latter phenomenon may reflect an effect of dehydration or DNA synthesis which prevents recombination. The occurrence of more T^+L^+ recombinants possessing the Lac^+ character than would normally be expected in both $F^+ \times F^-$ and $Hfr \times F^-$ crosses after a short period of donor cell dehydration and the decrease in their number after prolonged dehydration suggest that either the T^+L^+ Lac^+ unit is transferred more easily after cell dehydration and the Lac^+ DNA is more easily inactivated than the T^+L^+ DNA, or that the characters are transferred independently as a result of separation of the T^+L^+ and Lac^+ DNA by chromosome breakage. Even in the latter case, however, the Lac^+ DNA would seem to be inactivated more quickly than the T^+L^+ DNA. Clearly, the removal of water from DNA by semi-dehydration has a pronounced effect on its *in vivo* activity and the effect may be more severe in some regions of the chromosome than others.

The use of recombination phenomena in studies of dehydration damage to microbial cells should therefore prove useful in determining the reasons for the various known effects and may assist in understanding the mechanisms of recombination. Detailed studies using selected and unselected markers and blender separations of conjugants after given times of incubation are under way and will be reported in the near future.

LETTERS TO THE EDITOR

ASTRONOMY

Interpretation of Cosmic Microwave Background

THE discovery of microwave background radiation by Penzias and Wilson[1] is one of the most interesting events in observational astronomy in recent years. On the basis of the first observations at a single wavelength, the radiation was interpreted[2] as being of the black-body type, and it was concluded that this was the remnant of the primordial radiation of a big-bang universe. Later results by different observers have strengthened this interpretation. Indeed it is now claimed[3,4] that the black-body curve applies for a wavelength range of 1 90, and corresponds to a temperature $T=2.68°$ K. The observers[5] go as far as to state that the exact black-body intensity curve

$$\mathcal{J}(\nu) \propto \frac{\nu^3}{e^{h\nu/kT}-1} \tag{1}$$

fits the observations better than the "grey-body" approximation at long wavelengths—namely

$$\mathcal{J}(\nu) \propto \nu^2 \tag{2}$$

The purpose of this communication is to examine this interpretation in the light of available information about the universe. We begin by noting that if the observations are taken at their face value, one of the two possible conclusions can be drawn.

(I) The entire observed cosmic background is in fact the remnant of the primordial black-body radiation.

(II) If there are other processes operative in the universe capable of producing a microwave background of the observed magnitude, the present observations disprove (I).

It must be emphasized that for (II) to hold, it is not necessary that the microwave radiation produced by the other processes should follow the law (1) or (2). It is only necessary that the contribution be comparable with that observed in the relevant frequency range.

A few months ago one such process was indeed suggested[6,7]. The process consists of the absorption of optical and ultraviolet radiation from stars and its re-radiation at longer wavelengths by impurity oscillators in the interstellar dust grains of galaxies. This process could operate in all galaxies provided interstellar dust is present. It was also shown that in the steady state universe, because of the red-shift effect, radiation along a line with frequency $\nu=\nu_0$ is smeared out in the form of a spectrum

$$\mathcal{J}(\nu) \propto \begin{cases} \nu^3 & \nu \leqslant \nu_0 \\ 0 & \nu > \nu_0 \end{cases} \tag{3}$$

The actual spectrum observed would be a superposition of several such spectra, arising from different ν_0.

Although this calculation refers to the steady state universe, the process in question could equally well operate in a big-bang universe, but there are two points of difference. The red-shifts permitted in the steady state universe can be infinite, in the big-bang universe, there is an upper limit set by the epoch of galaxy formation. At present we have no definite theory of galaxy formation available to fix this epoch, but red-shifts up to $z \simeq 100$ may still be permitted. Such a factor is sufficient to bring the far infrared frequencies into the microwave range[7]. The second point of difference arises in that the evolutionary cosmologies permit the use of arbitrary epoch-dependent functions—a freedom denied to the steady state theory. Such functions have been extensively used[8,9] to make the predictions of big-bang universes agree with observations.

On the assumption that there is no epoch-dependence, however, the function $\mathcal{J}(\nu)$ corresponding to a single line $\nu=\nu_0$ may be computed in a relativistic cosmological model. The calculation is particularly simple if we assume that only the matter density makes a significant contribution to T^{ik} in the Einstein equation—an assumption which seems to be justified from our present knowledge of the universe. The result can be expressed in terms of q, the deceleration parameter[10]. We have

$$\mathcal{J}(\nu) \propto \begin{cases} \dfrac{\nu^{3/2}}{\sqrt{2q\nu_0-(2q-1)\nu}} & \text{for } \nu_1 \leqslant \nu \leqslant \nu_0 \\ 0 & \text{otherwise} \end{cases} \tag{4}$$

Here ν_1 is the lower limit set by the epoch of galaxy formation. (This form of $\mathcal{J}(\nu)$ can be altered almost at will by the use of arbitrary epoch-dependent functions, so that we attach no special significance to it.) For the Einstein–de Sitter universe, $q=\frac{1}{2}$ and $\mathcal{J}(\nu) \propto \nu^{3/2}$. For the empty hyperbolic universe $q=1$ and $\mathcal{J}(\nu) \propto \nu$.

It remains to discuss the order of magnitude of this radiation. Shakeshaft and Webster[4] have argued that the black-body radiation density is about 400 times greater than the energy density of star-light from all galaxies, and quote this result from a review by Davidson and Narlikar[10]. We wish to point out that the factor arose on the hypothesis that the radiation was of the black-body type. The radiation density corresponding to a black-body radiation temperature is

$$\sim 3.8 \times 10^{-13} \text{ erg cm}^{-3} \tag{5}$$

This energy density corresponds, however, to radiation over all frequencies. We are here concerned only with a limited wavelength range over which radiation has actually been observed, namely, from 36.6 GHz to 408 MHz, the factor of 1 90 quoted by Shakeshaft and Webster[4]. (In fact the process considered by us does not operate over all frequencies, as is clear from (3) and (4).) The radiation density over the observed range is less than

$$\sim 6 \times 10^{-15} \text{ erg cm}^{-3} \tag{6}$$

a figure comparable with the optical radiation density (Davidson and Narlikar, *op cit* page 553). Furthermore, we had allowed ourselves a factor 10–100 over and above the optical radiation density in young galaxies (not the local galaxy as quoted by Shakeshaft and Webster). We conclude therefore that there is no energy difficulty associated with this process.

Shakeshaft and Webster[4] have raised objections to the mechanism of themalizing starlight. We fail to see the relevance of their arguments. While it is true that there are essential and vital differences between the electrical properties of graphite and those of alkali halides, these differences are clearly not significant for the process we consider. A weakly bound impurity atom or ion in any crystal lattice would be expected to have a localized low frequency oscillation mode, the frequency of which is determined almost entirely by the ratio of its mass to that of the host crystal atom and by the force constants of its attachment to the lattice. We cannot also follow their arguments against the possibility that all the impurities may be lodged in the outer dielectric mantles of the grains. On the basis of grain models which agree with extinction and polarization data we require the outer dielectric mantle to be about 100 times more massive than the graphite core. It would indeed seem likely that most of the impurities are lodged in the dielectric mantles, and about 10^4 such impurity atoms[6] suffice to re-radiate the absorbed starlight in the far infrared.

We therefore feel that such a process could very well operate in galaxies with interstellar dust and make a substantial contribution to the microwave background We do not suggest that this is the only source of microwave background It is of interest in this connexion that Partridge and Wilkinson[11] have recently reported a slight increase in the background radiation at the 3 2 cm wavelength from a region of the sky which is close to the galactic plane Kurilchik and Kokin[12] have also detected a microwave flux at 8 cm wavelength from two individual quasi-stellar objects BSO 1 and Ton 730 Very recent infrared surveys (Low[13]) have actually revealed the remarkable fact that several galaxies emit ~100 times more radiation in the far infrared than in the visible spectral region It is entirely conceivable that later and more systematic surveys of discrete sources at long wavelengths would produce further evidence of a contribution to the microwave background from such sources

We now turn to the cosmological aspects of the problem If the aforementioned process takes place in a big-bang universe, we fail to see how the combined curve of this process plus the primordial black-body radiation could lead to the purely black-body curve (1) Our own view is that the "black body" explanation has been overstated and that the actual form of $\mathcal{J}(\nu)$ may not be so simple For this reason, it is also premature to conclude from the present observations that the steady state theory of the universe is untenable

Interstellar Extinction by Quartz Grains

KNACKE[1] has pointed out that quartz particles possess strong absorption bands at $\lambda \sim 10\mu$ Although these features occur in the spectral region 3–10μ, where Johnson[2] has found humps in interstellar extinction curves, by itself this cannot be taken as indicating a silica component in the interstellar grains It has already been pointed out[3] that impurities in any solid with a Debye frequency close to that of graphite would give optically active lattice bands at $\lambda \sim 10\mu$* Further evidence would be necessary before quartz could be considered as a serious alternative to interstellar graphite grains

From an approximate calculation, Knacke[1] has claimed that silica grains of radii ~ 0 2μ would fit the observed interstellar extinction curve in the wavelength range 0 3–1 5μ to within about 15 per cent, but the extension of the observed extinction curve into the far ultraviolet region[4,5] has greatly enhanced the sensitivity of this test[6] It is therefore of interest to compute accurate extinction cross-sections for quartz particles and particles with a quartz core and ice mantle for the entire wavelength range of the observations We have performed such calculations for single-sized quartz particles, quartz particles with an Oort–van de Hulst[7] distribution of radii and for quartz particles covered with ice mantles

Calculations of the cross-sections for homogeneous quartz particles were done using the Mie theory and those for the composite particles using the Guttler theory (see, for example, ref 8) The results of our calculations are shown in Figs. 1–3 We have adopted a normalized extinction F_λ defined by

$$F_\lambda = \frac{0\ 5\,[Q(\lambda) - Q(0\ 5556\mu)]}{Q(0\ 4464\mu) - Q(0\ 5556\mu)}$$

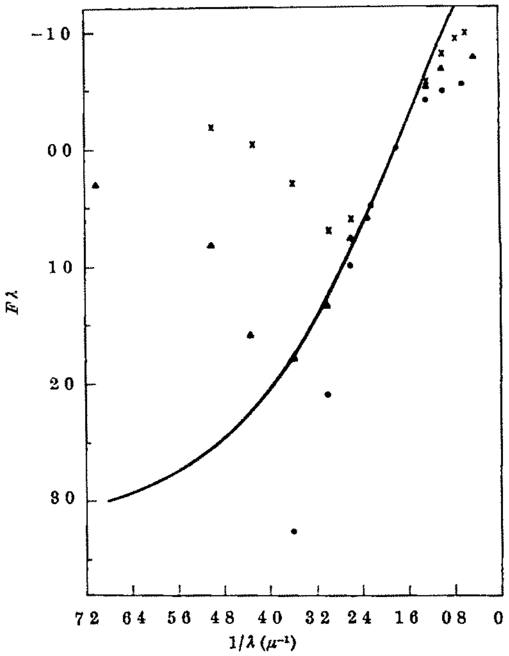

Fig 1 Comparison of the theoretical extinction curve for single homogeneous quartz grains with observations The solid line denotes the smoothed curve drawn through the observations ●, $r = 0\ 10\mu$, ▲, $r = 0\ 15\mu$, ×, $r = 0\ 20\mu$

---

* The phonon spectrum of reactor grade graphite shows the strongest pile up of phonon states at ~ 7μ (ref 9)

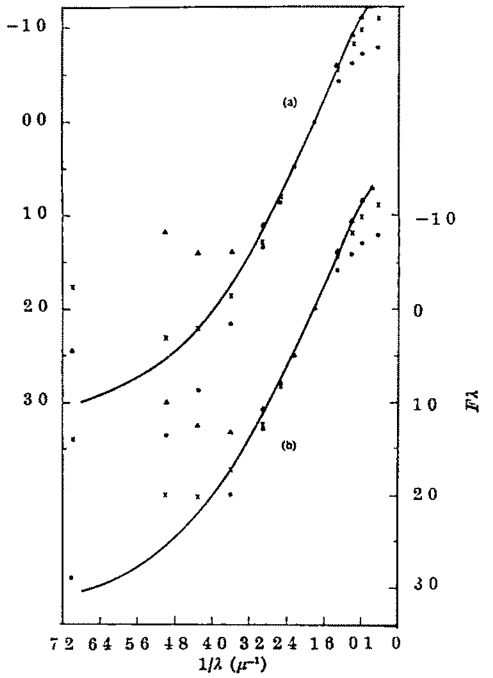

Fig 3 Comparison of the theoretical extinction curve (for quartz ice particles) with observations The solid line denotes the smoothed curve drawn through the observations (*a*) Core radii = 0 04μ ●, outer radius = 0 14μ, ×, outer radius = 0 19μ, ▲, outer radius = 0 24μ (*b*) Core radii = 0 05μ ●, outer radius = 0 15μ, ×, outer radius = 0 20μ, ▲, outer radius = 0 25μ

where $Q(\lambda)$ is the integrated extinction cross-section The solid curves represent the observed extinction[5] normalized in the same way

In all the cases we have considered, no agreement is possible over the entire wavelength range of the observed interstellar extinction curve

Although pure quartz is a pure dielectric, if quartz particles exist in the interstellar medium they may be expected to contain an appreciable quantity of impurities which contribute an imaginary component to their refractive index Accordingly we repeated our calculations taking the complex refractive index to be $m(\lambda) = n(\lambda) - 0\ 1\,i$, where $n(\lambda)$ is the refractive index appropriate to pure quartz The results for the impure quartz are not significantly different from those plotted in Figs 1-3 for pure quartz

Thus it seems most unlikely that quartz particles can form any appreciable component of the interstellar grains We have also recently examined in some detail the conditions required for the formation of silica grains in M stars (our unpublished results) We performed chemical equilibrium calculations including about 60 molecular species and concluded that the condensation of silica requires temperatures ~1,000° K—less than the boundary temperature of these stars

Is Interstellar Hydrogen capable of Maser Action at 21 Centimetres?

THREE sets of observations suggest that the density of interstellar neutral hydrogen may be less than the value usually inferred from 21 cm emission line measurements This possible discrepancy is found in observations of (*a*) the incoming high velocity neutral hydrogen clouds which, according to Oort[1], deposit material on to the galactic disk at an alarmingly large rate, (*b*) the ultraviolet spectra of stars in Orion which show an unexpectedly weak interstellar Lyman-α absorption line[2,3], and (*c*) the X-ray background at ~50 Å which suggests that the opacity of the Galaxy is less than would be estimated from the observed column density of neutral hydrogen[4]

Shklovskii[5], following Varshalovich[6], has attempted to resolve (*a*) by invoking maser action in the 21 cm line of interstellar hydrogen, made possible by a population inversion of the hyperfine levels of the ground state arising from Lyman-α pumping This mechanism would operate selectively on the incoming clouds and would lead to an overestimate of their mass Fischel and Stecher[7] have made a similar suggestion to explain (*b*) One might also consider this process in connexion with (*c*) (ref 8) We wish to point out that a detailed consideration of the Lyman-α pumping mechanism shows that it is unlikely to be of importance in resolving these problems

In his theoretical analysis, Varshalovich has shown that population inversion of the hyperfine levels of the ground state of neutral hydrogen can occur in a region of high Lyman-α density, where the excitation conditions are determined by Lyman-α absorption and not by spin-exchange collisions The criterion for inversion in such a region is

$$\frac{\mathrm{d}n(\nu)}{\mathrm{d}\nu} > 2\times 10^{-32}\ \text{photons Hz}^{-2}\ \text{cm}^{-3} \qquad (1)$$

where $n(\nu)\,\mathrm{d}\nu$ is the number density of photons of frequency between ν and $\nu+\mathrm{d}\nu$ in the Lyman-α radiation field When inversion occurs, the spin temperature in degrees absolute is given by

$$T_s = -6\ 81\times 10^{-2}\ \frac{n(\nu)}{\nu_0\,\dfrac{\mathrm{d}n(\nu)}{\mathrm{d}\nu}} \qquad (2)$$

where $\nu_0 = 1\ 42\times 10^9$ Hz, and the gain at the centre of the 21 cm line for a region of length L cm is given by the expression

$$\tau_0 = \frac{3}{32\pi\,\Delta\nu_0}\frac{c^2}{\nu_0^2}\,A_{12}\,N_{\mathrm{H}}fL \qquad (3)$$

where $A_{12} = 2\ 85\times 10^{-15}\ \text{s}^{-1}$, Δv_0 is the Doppler width of the 21 cm line, typically $\sim 5\times 10^4$ Hz, N_{H} is the density of neutral hydrogen in atoms cm^{-3} and the degree of inversion f is given by

$$f = \frac{g_0 N_1}{g_1 N_0} - 1 = \frac{-6\ 81\times 10^{-2}}{T_s} \qquad (4)$$

The subscript 1 refers to the $F=1$ triplet state of the $1S_{\frac{1}{2}}$ level of neutral hydrogen and the subscript 0 to the $F=0$ singlet state

At the edge of a typical HII region, the Lyman-α radiation density $\sim 4\times 10^{-3}$ Lyman-α photons cm^{-3} (ref 8) If the Lyman-α profile in the region of half maximum in the red wing of the line has a Doppler shape of width $\Delta\nu_D \sim 8\times 10^{10}$ Hz, corresponding to a temperature of 10^4 °K in the HII region, then in this part of the line profile

$$\frac{\mathrm{d}n(\nu)}{\mathrm{d}\nu} > 10^{-26}\ \text{photons Hz}^{-2}\ \text{cm}^{-3}$$

and

$$\frac{n(\nu)}{\nu_0\,\dfrac{\mathrm{d}n(\nu)}{\mathrm{d}\nu}} \sim \frac{(\Delta\nu_D)^2}{2\nu_0\,\Delta\nu} \qquad (5)$$

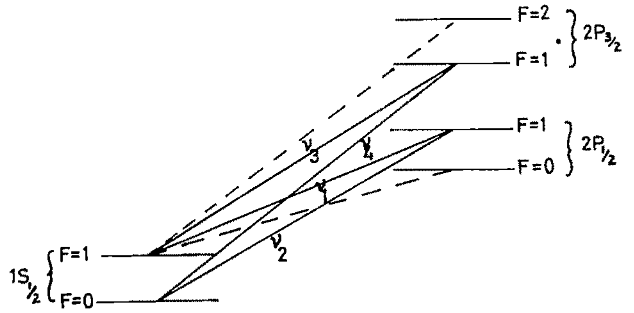

Fig. 1. The $1S$ and $2P$ energy levels of neutral hydrogen, showing the allowed transitions excited by Lyman-α – – –, Complementary transitions.

where $\Delta\nu$ is the displacement from the central maximum. For $\Delta\nu = 2\Delta\nu_D$

$$\frac{n(\nu)}{\nu_0 \dfrac{dn(\nu)}{d\nu}} \sim 14$$

Thus if blue-shifted Lyman-α radiation from an HII region is incident on neutral hydrogen, population inversion in the $1S_{\frac{1}{2}}$ state will occur, with $T_s \sim -1°$ K from (2) and $f \sim 0.07$ from (4).

Fischel and Stecher consider a model of the Orion Nebula in which the neutral hydrogen is moving with a velocity $\sim +10$ km/s with respect to the central HII region. They assume that, in these conditions, a maser region ~ 5 pc thick will be formed, with a gain $\tau_0 \sim 0.8$ (from equation (3) with $f \sim 0.07$ and $N_H \sim 1$ cm^{-3}). This, however, neglects the very rapid thermalization of the Lyman-α spectrum as the radiation enters the neutral hydrogen region. With an absorption coefficient in the line centre, $k_0 = 5.4 \times 10^{-13}$ cm^2, 5 pc of neutral hydrogen of density 1 cm^{-3} has an opacity for Lyman-α of $\tau_a = 8 \times 10^6$. The transfer problem for Lyman-α in neutral hydrogen has not been accurately solved, but the results of Unno[10] and Field[11] show that complete thermalization of the profile would occur well within a region of optical depth $\tau_a = 10^2$. Thus appreciable inversion can only occur in a zone of thickness $\sim 6 \times 10^{-5}$ pc at the edge of the neutral hydrogen region.

To ensure that, within this zone, the total rate of Lyman-α absorption is greater than the spin exchange collision rate for a gas of density ~ 1 cm^{-3} (which is required for inversion to occur at all) it is necessary for $\Delta\nu$ to be less than 4 $\Delta\nu_D$. If this inequality holds then

$$\frac{n(\nu)}{\nu_0 \dfrac{dn(\nu)}{d\nu}} > 7$$

(from (5)), giving a maximum possible degree of inversion $f \sim 0.14$ with $T_s \sim -0.5°$ K (for negative spin temperature a smaller value of $|T_s|$ gives a larger degree of inversion).

Thus the very large opacity of neutral hydrogen for Lyman-α reduces the gain of the maser zone in the Fischel and Stecher model of Orion from $\tau_0 \sim 0.8$ to a maximum of $\tau_0 \sim 2 \times 10^{-5}$. Accordingly no significant amplification of the background radiation will occur. The same conclusion has also been reached independently by Van Bueren and Oort[12].

Shklovskii has considered the possibility of Lyman-α pumping in neutral hydrogen clouds of density $N_H \sim 10^{-3}$ cm^{-3} and diameter ~ 100 pc in the galactic corona. He attempts to overcome the problem of the rapid thermalization of the Lyman-α profile by assuming that, if the incident Lyman-α spectrum is growing exponentially, most of the absorption will occur in the far violet wing of the absorption profile of the neutral hydrogen. In the far wing the absorption cross-section $k \sim 10^{-18}$ cm^2 and the clouds will be optically thin. However, if most of the absorption does occur in the violet wing, the theoretical analysis of Varshalovich cannot be used to calculate the degree of inversion produced by the Lyman-α radiation field.

Consider the energy level diagram of the $1S$ and $2P$ states of neutral hydrogen (see Fig. 1). Of the six allowed hyperfine transitions $1S \rightarrow 2P$ excited by Lyman-α, four produce mixing of the ground state populations. (The two complementary transitions $1S_{\frac{1}{2}} \rightarrow 2P_{\frac{3}{2}}$, $1S_{\frac{1}{2}} \rightarrow 2P_{\frac{1}{2}}$ cannot mix the populations and will not be considered in the following discussion.) Each of these four transitions has an absorption profile centred on its transition frequency, as shown schematically in Fig. 2. The width of each line $\gamma \sim 10^8$ Hz (the natural width of the $2P$ state) and the separation of the lines $\nu_2 - \nu_1 \sim 10^9$ Hz. At frequencies close to the absorption peaks there is very little overlapping of the separate absorption profiles (since $\gamma \lll \nu_2 - \nu_1$). Appreciable overlapping does occur, however, in the wings (see Fig. 2), where the absorption coefficient for the ν_n hyperfine transition has the form

$$K_n(\nu) = \frac{K_{n0}}{1 + \left(\dfrac{2(\nu - \nu_n)}{\gamma}\right)^2}$$

For $\nu - \nu_n \sim 10^{11}$ Hz, $\gamma \sim 10^8$ Hz the absorption coefficients for the separate hyperfine transitions differ by at most 3 per cent. This difference decreases as $\nu - \nu_n$ increases.

In his analysis, Varshalovich assumes that the Lyman-α absorption in the wings is negligible. If absorption occurs near the line centre, where there is little overlap of the individual absorption coefficients, the relative populations of the ground state hyperfine levels will be determined by the gradient of the Lyman-α spectrum near the line centre and equations (1) and (2) can be used to calculate the resultant population inversion. If, however, most of the absorption takes place in the wings where the separate absorption lines overlap, any preferential absorption into a particular hyperfine state will be caused not by the rapidly growing Lyman-α spectrum but by the small difference between the overlapping absorption coefficients. Because such differences are so small and decrease as $(\nu - \nu_n)$ increases, the resultant degree of inversion will be less than that obtained by Shklovskii using the results of Varshalovich. An approximate calculation shows that it is not possible to get a degree of inversion $f > 5 \times 10^{-4}$ by means of this slight preferential absorption in the violet wing. No significant overestimation of the mass of the coronal clouds would result from this small degree of masing and no significant selection of incoming clouds would occur.

We conclude that the very large opacity of neutral hydrogen for Lyman-α makes it exceedingly difficult to form an extended region of appreciable population inversion of the hydrogen ground state by means of Lyman-α pumping. The very small masing zone formed at the surface of an HI region moving relative to an HII region can-

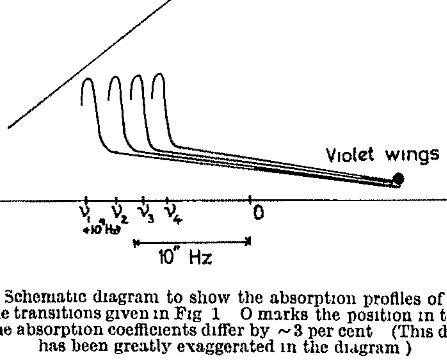

Fig. 2. Schematic diagram to show the absorption profiles of the four hyperfine transitions given in Fig. 1. O marks the position in the wings where the absorption coefficients differ by ~ 3 per cent. (This difference has been greatly exaggerated in the diagram.)

not produce significant amplification of the background radiation Accordingly, the problems raised by the observations (*a*), (*b*) and (*c*) described at the beginning of this communication probably have to be resolved without invoking a maser mechanism in interstellar hydrogen

Cosmogonic Fragmentation

Cosmogony probes the evolution of a cosmic system by entertaining a variety of hypotheses about its origin It is valuable to distinguish these, as far as possible, from any specific mechanisms they may assume Thus many hypotheses call for some, but not necessarily a particular, mechanism for fragmenting cosmic masses[1-5] This communication concerns one possible fragmentation mechanism—gravitational instability in anisotropic expansion—which can operate effectively under diverse hypotheses

In this communication, I argue that this is a feasible mechanism for cosmogonic fragmentation in that (1) linear instability can be strong, and (2) nonlinearities need not bar permanent fragmentation, but (3) they can control excessive subfragmentation I then indicate some of the hypotheses yielding anisotropic expansion, with special reference to star formation In that case, the value of distinguishing mechanisms from hypotheses will be particularly in evidence, in that (4) under a generally accepted hypothesis, suitably elaborated, the proposed mechanism can yield acceptable protostar masses

Gravitational stability theory shows that anisotropic expansions can permit exponential growth of density fluctuations ($\delta\rho/\rho$), in contrast to the weak algebraic instabilities of a spherical expansion The essential physical reason for this is that the density, and therefore the fluctuations of self-gravity ($\propto \rho\ \delta\rho$), can decrease with time sufficiently slowly in anisotropic expansion To see this mathematically, I shall confine attention to the limit of long waves in uniform media for which (sum convention)

$$\left(\frac{\mathrm{d}^2}{\mathrm{d}t^2} - 4\pi G\rho\right)\frac{\delta\rho}{\rho} = 2\frac{\partial u_i}{\partial x_j}\frac{\partial v_j}{\partial x_i} \text{ and } \frac{\mathrm{d}}{\mathrm{d}t}\frac{\delta\rho}{\rho} = -\frac{\partial v_i}{\partial x_i} \qquad (1)$$

where u_i are cartesian components of unperturbed flow and v_i their linear perturbations This extends Jeans' static case, $u_i = 0$, $\rho =$ constant, with instability $\delta\rho/\rho \propto \exp\sqrt{4\pi G\rho}\ t$, and may be generalized further (Layzer, private communication) Clearly, expansion tends to be less unstable because ρ decreases with t In fact, for a uniform spherical expansion $u_i = -\frac{1}{3}(\rho/\rho)\ x_i$, equation (1) yields the known[6] maximum instability

$$\frac{\delta\rho}{\rho} \sim t^n, \quad n = -\frac{1}{6} + \sqrt{1/36 + 4\pi G\rho t^2} = \frac{2}{3} \qquad (2)$$

because $\rho \sim 1/6\pi G t^2$ at best (zero energy) For an expansion such that $\rho \sim t^{2\varepsilon-2}$ with $\varepsilon > 0$, however, equation (1) shows that the dominant behaviour as $t \to \infty$ remains exponential

$$\frac{\delta\rho}{\rho} \propto \exp\int\sqrt{4\pi G\rho}\ \mathrm{d}t = \exp k\ t^{\varepsilon} \qquad (3)$$

($k =$ constant) provided the velocity term in (1) is asymptotically weak compared with $4\pi G\delta\rho$ for at least some mode This is possible for some anisotropic expansions

As an extreme example, for a one-dimensional explosion (or ' high energy jet", see ref 7) for which $u_i = -(\dot\rho/\rho)\ \delta_{i1} x_1$ and $v_i = \delta_{i1} v_1$, equation (1) gives

$$\frac{\delta\rho}{\rho} \sim \rho\exp\int\sqrt{4\pi G\rho}\ \mathrm{d}t \sim \frac{1}{t}\exp k\ t^{\frac{1}{2}} \qquad (4)$$

because $\rho \sim k^2/16\pi G t$ with $k^2 = 16\pi G\rho_0\tau_0$ where ρ_0, τ_0 are density and explosion time at $t = 0$ For a more general spheroidal expansion, analysis—to be given in detail elsewhere—gives, for axial modes and zero energy,

$$\frac{\delta\rho}{\rho} \sim \rho^{\frac{1}{4}}\exp\int\sqrt{4\pi G\rho}\ \mathrm{d}t \sim \frac{1}{t^{1/3}}\exp k\left(\frac{t}{\log t}\right)^{1/3} \qquad (5)$$

(in equation (1), $v_i = \delta_{i3} v_3$, $\partial u_i/\partial x_3 = -\frac{1}{2}(\rho/\rho)\ \delta_{i3}$, and $\rho \sim k^2/36\pi G t^{4/3}(\log t)^{2/3}$) Other expansions present similar possibilities, provided $\rho > 1/t^2$, although detailed examination is required to see if effective instability is realized at finite wavelengths, for non-uniform ρ, and so on Moreover, linear analysis breaks down as $\delta\rho \to \rho$ Second order effects may, however, be expected to assist any instability because the total density $\rho + \delta\rho$ of a condensation, and its self-gravity then decrease still less rapidly than ρ

The virtues of an expansion become apparent in the nonlinear regime First, incipient fragmentation is not menaced by nonlinear interactions, as it would be in a contraction[8] Thus Layzer has argued cogently that in a contracting system the nonlinear interaction between such fragments as might form would make them ephemeral, incipient fragmentation would degenerate into turbulence In an expansion, however, the interfragment forces are diminishing and might be expected to attenuate to impotency[9] Second, once fragments begin to condense out of the expanding milieu, these same nonlinearities within a fragment can curb subfragmentation This neatly avoids another difficulty of fragmentation during a contraction—the problem of stopping the mechanism once started if excessive fragmentation is to be avoided (see ref 1, p 360)

Fragmentation need not, of course, occur in all expansions, any more than in all contractions (and for a cosmological expansion, Layzer[1] proposed the antithesis "clustering"), but the possibility does arise in anisotropic expansions

Hypotheses (and observations) which involve expansion are not uncommon Pre-eminent among these is the universal expansion, which, however, at present seems closely isotropic In any case, these considerations do not apply to cosmological problems proper except to the extent that appropriately anisotropic Newtonian cosmology would be an adequate approximation On a smaller scale, it has recently been suggested that asymmetric gravitational collapse may rebound to an expansion which is approximately Newtonian[10] On a galactic level, many observations suggest explosive events[11] Ejections from galactic nuclei were an early hypothesis, and the associated concept that quasars are relics in delayed development from a superdense past also involves expansion[12] Furthermore, in star formation theory, whereas the familiar hypothesis (*A*) "interstellar cloud→star cluster" usually assumes a mechanism of fragmentation during contraction[13], Ambartsumian[2] long ago proposed an alternative hypothesis (*B*) "superdense body→stars (+ gas)" which calls for fragmentation during expansion In fact it is interesting that the hypothesis (A) which is perhaps more plausible, leads to a similar result if the assumption of fragmentation during contraction is not made, it is not an indispensable assumption and there is reason not to adopt it Thus to explain stellar association phenomena it was suggested[3] that contraction *en masse* may lead to (nuclear) explosion In other words, (A) is elaborated to the form (A') "interstellar cloud→massive condensation→stellar association", and detailed calculations have lent this support[4] Explosions, perhaps of a related nature, are suggested by many other phenomena[3,4,5,7,14,15]

Anisotropy of any of the hypothesized expansions—except the cosmological—is probable It can arise from appropriate initial conditions or from constraining forces For example, the massive condensation in (A') evolves to a dense, hot, rotating disk which, by an unconventional pulsation instability, is liable to explode[4] This would produce initial motion predominantly along the axis, so that the spheroid would expand from oblate to prolate form Resistance from a surrounding medium could constrain the motion essentially to one dimension, at least for a time Magnetic constraint is another possibility

For the star formation theory based on (A'), detailed analysis of a self-gravitating, rotating, spheroidal expansion (see equation (5)) shows that modes with axial wavelength greater than transverse wavelength can grow exponentially at such a rate as to produce fragmentation when the disk has expanded to a cigar shape of length some tens times its radius, provided the (total) energy is not as large as self-gravity at that time From a generalized Jeans criterion of instability, it can be deduced that the fragments would have minimum mass typically $\sim \frac{1}{100}$ to $\frac{1}{10}$ $M_{\odot}$, and so may evolve to acceptable stars Without going into detail, we may note that in other respects, however, the fragments can differ remarkably from the conventional picture of "protostars" This could, for example, explain the apparent anomaly of T Tauri stars below the main sequence (see page 64 in ref 12), although such phenomena may also be understood, for not too small masses, as a natural outcome of the evolution of rotating protostars of the conventional sort[16]

I thank Professor David Layzer for suggesting the presentation through equation (1), and other valuable comments This work was supported by the Bureau of Naval Weapons, US Department of the Navy.

Discussion of the "Forbidden" Intercombination Transition of C_2 in Comets

THE only comet emissions known to arise from the C_2 radical are the Swan bands of the triplet electronic system ($A\,^3\Pi_g \rightarrow X'\,^3\Pi_u$) (ref 1) The absence of definitive evidence for singlet system emissions has led to speculation that C_2 must be formed directly in the triplet state either by a primary photochemical process or by direct sublimation from the icy nucleus[2,3] These speculations have been supported by the widely accepted view that the singlet and triplet states of C_2 cannot be exchanged by either a radiative or a collisional process Because the radiative intercombination transition for C_2, $X'\,^3\Pi_u \leftrightarrow x\,^1\Sigma_g^+$, is "forbidden", it has been assumed not to occur More specifically, Ballik and Ramsay[4], state that a lifetime of several days would not be unlikely for this transition Because the gas density in the coma is very low, collisional processes have also been assumed not to occur The exclusive observation of triplet C_2 is particularly disturbing because the $x\,^1\Sigma_g^+$ state has been shown to be the ground state and the observed triplet system originates from the $X'\,^3\Pi_u$ state which is 610 cm^{-1} above the ground state[4] This emission is in contrast to all other emissions which are observed in fluorescence from the ground state

The purpose of this note is to demonstrate that the "forbidden" radiative process is likely to occur during the travel time of the radical in the coma, and to point out some of the consequences of this process Escape velocities of radicals in a comet coma are of the order of thermal velocities (1 km s^{-1}) and the radius of the coma may exceed 3×10^5 km (ref 2) This results in a radical travel time of approximately 3 or 4 days Although collisions probably do occur in the inner coma[5], any effect they might have on the singlet–triplet interchange will be neglected and only the radiative process will be discussed here

The relationships determining the radiative lifetime of an excited state can be written simply as follows To a first approximation, the spontaneous transition probability is

$$A_{v'v''} = K\nu^3 R_e^2\,(\bar{r}_{v'v''})\,q_{v'v''} \tag{1}$$

where $A_{v'v''}$ is the Einstein coefficient, K is a constant involving units and geometry, ν is the frequency of the transition, R_e is the electronic transition moment, $(\bar{r}_{v'v''})$ is the r centroid of the transition and $q_{v'v''}$ is the Franck–Condon factor The Franck–Condon factor, $q_{v'v''}$, associated with the (v,v'') band is defined by the square of the vibrational overlap integral

$$q_{v'v''} = [\int \psi_{v'} \psi_{v''} \mathrm{d}r]^2 \tag{2}$$

The lifetime of the v' level for transition to v'' is simply the reciprocal of the Einstein coefficient

$$\tau_{v'v''} = \frac{1}{A_{v'v''}} \tag{3}$$

This is the time required for decay of all but exp(-1) of the molecules in state v' The mean lifetime of all the levels of v' for transition to all possible lower levels, v'', is

$$\tau = \Big[\sum_{v'v''} Q_{v'} A_{v'v''}\Big]^{-1} \tag{4}$$

where $Q_{v'}$ is the fractional number of molecules in the v' level Using these relationships and with the assumption that the ratio of the spontaneous transition probabilities for the transitions are proportional to the ratio of the factors $\nu^3 q_{v'v''}$ for the respective transitions, the lifetime of the intercombination transitions for C_2 can be estimated by comparison with a known lifetime for a system of similar forbiddenness The lifetime derived using this scheme depends on the validity of drawing an analogy between the electronic transition moments for different electronic transitions, and therefore is only approximate It can be used, however, to generate estimated lifetimes in lieu of experimental knowledge of the transition probabilities Potential curves for the lower electronic states of interest are readily available and will not be included here[6,7]

A transition similar to the intercombination transition of C_2 is the $C\,^3\Pi_u \leftrightarrow X\,^1\Sigma_g^+$ transition of N_2 Both transitions violate only the weak selection rule $\Delta S = 0$ and in both cases the excited triplet states have singlet states of the same symmetry nearby (C_2, $b\,^1\Pi_u$ and N_2, $b'\,^1\Sigma_u^+$), which can mix with the corresponding triplet states giving the latter some singlet character and making the transitions more probable The lifetime of the $v' = 0$ level of the $C^3\Pi_u$ state of N_2 with respect to transition to the $v'' = 0$ level of the $X\,^1\Sigma_g^+$ state is approximately $2\ 5 \times 10^{-3}$ s This lifetime has been derived from the data of Wilkinson and Mulliken[8] using the recently determined Franck–Condon factor for the transition[9] The mean lifetime of the C_2 transition will be estimated below using this value

The absence of vibrational–rotational transitions of C_2 in the coma results in a vibrational population corresponding to an approximate Boltzmann temperature of 6,000° K (ref 10) In order to determine the mean lifetime of the upper electronic state it is therefore important to consider decay from the upper vibrational levels because some of them will be appreciably populated at this temperature The levels up to and including $v = 4$ have been considered here because they comprise approximately 90 per cent of the total population of the C_2, $X'\,^3\Pi_u$ state at 6,000° K Table 1 lists the normalized Franck–Condon factors and the band origins in cm^{-1}, $\omega_{v'v''}$, for the transitions between the vibrational levels of the electronic states, calculated from the constants tabulated by Ballik and Ramsay[6] The Franck–Condon factors have been evaluated graphically using the eigenfunction for the harmonic oscillator Although the use of this wave function can lead to serious errors, the fact that the values reported here satisfy the sum rule, $\sum_{v'} q_{v'v''} = 1$, indicates that they are adequate for our purpose The C_2 radiative lifetimes for these levels $\tau_{v',v''}$, calculated by comparison with the (0,0) band of the $C^3\Pi_u - X\,^1\Sigma_g^+$ transition of N_2, are also listed in this table Using these values, the mean lifetime of the $X'\,^3\Pi_u$ state calculated from equation (4) is 3 min Because of the similar energies of the two electronic states, radiative transitions can also occur from the "lower" $x\,^1\Sigma_g^+$ state to the "upper" $X'\,^3\Pi_u$ state The mean lifetime for the $x\,^1\Sigma_g^+$ state, assuming a 6,000° K vibrational temperature, is 4 min The calculated lifetimes for the $X'\,^3\Pi_u$ and the $x\,^1\Sigma_g^+$ states of C_2 are more than three orders of magnitude smaller than the radical travel time This result therefore strongly suggests that the intercombination transition does occur in the coma

Table 1 WAVENUMBER OF THE BAND ORIGINS ($\omega_{v',v''}$, CM^{-1}), FRANCK–CONDON FACTORS ($q_{v',v''}$) AND LIFETIMES (τ, S) FOR SOME OF THE MOST PROBABLE TRANSITIONS FOR THE LOWER LEVELS OF C_2, $X'\,^3\Pi_u \leftrightarrow x\,^1\Sigma_g^+$

In all cases except (0,0), the life-times are for transition from the higher numbered to the lower numbered vibrational level

The consequences of this radiative transition in the coma must be considered in relation to a possible mechanism suggested by Ballik and Ramsay for the production of a triplet from the singlet C_2 radical[4] The mechanism involves optically pumping the vibrational–rotational levels of C_2, $x\,^1\Sigma_g^+$ by absorption and emission in the Phillips system, $b\,^1\Pi_u \rightarrow x\,^1\Sigma_g^+$, followed by a perturbational crossing from the $x\,^1\Sigma_g^+$ state to the $A'\,^3\Sigma_g^-$ with subsequent radiation to the $X'\,^3\Pi_u$ state The production of the $x\,^1\Sigma_g^+$ from the $X'\,^3\Pi_u$ by the reverse radiationless process is less likely because of the negligibly small concentration of $A'\,^3\Sigma_g^-$ with respect to $x\,^1\Sigma_g^+$ The possibility of this mechanism for radiationless production of the triplet state from the singlet state concurrent with the possibility of the radiational interchange of the singlet and triplet states suggested here would result in a steady state concentration of the $x\,^1\Sigma_g^+$ and the $X'\,^3\Pi_u$ states in the coma which would be independent of the state of production of C_2 The probability of observing Phillips emission near the comet nucleus depends on the state of production of C_2 but observation further out in the coma depends on the steady state concentration of the singlet and triplet which would be controlled by the rates of the competing processes If the steady state favoured the triplet concentration, the Phillips emission would be weak even if C_2 was formed entirely in the singlet state Failure to observe singlet system emission therefore cannot be used as evidence for the production of C_2 in the triplet state

Relatively few experimental observations of cometary spectra in the Phillips region have been reported Also, the measurements in this wavelength region are usually less sensitive than those in the visible because of the lower sensitivity of photoelectric and photographic techniques and because of the lower solar intensity Some reported photoelectric data suggest that the (3,0) and (4,1) bands of the Phillips system have been observed in comet Candy (1960*n*) (ref 11) The limited number of observations as well as the lower sensitivity of the measurements might account for the lack of more definitive evidence Higher resolution studies and observations at different distances from the comet nucleus would be helpful in resolving the C_2 question

Observations of Atmospheric Absorption in the Wavelength Range 2 mm to 300 μm

WE present here the results of experiments started in 1957, to which have been added some observations made in December 1967 using a new telescope at Hochalpine Forschungssation Jungfraujoch (altitude 3,580 m)

In 1957 we used a coelostat with 12 in diameter mirrors to illuminate a lamellar grating interferometer to obtain submillimetre solar spectra but in 1967 we had the benefit of a 30 in telescope recently installed by Grubb Parsons This had an NPL modular Michelson interferometer fitted at the coudé focus, and the combination gave us approximately ten times the light grasp of the earlier equipment For the recent observations, however, the total water vapour content was not as low as in 1957 because the length of the slant path was greater by at least a factor of two

A limited account of the 1957 results for wavelengths shorter than 1 mm was published shortly after the observations were made[1] and since then we have accounted for the chief features which were not explained in 1957 by assigning them to lines in the magnetic dipole pure rotation spectrum of molecular oxygen[2] The new observations completely support the 1957 results in this wavelength region with the oxygen features showing even stronger (Fig 1), in accordance with the increased air mass

The principal interest of the new observations, however, is at wavelengths longer than 1 mm (Fig 2) Between 6 cm^{-1} and 12 cm^{-1} there are two strong ground state rotational lines of H_2O^{16} at 6 12 cm^{-1} and 10 85 cm^{-1} but in the spectra recorded in 1957 there were in addition well marked features in the region of 7–9 cm^{-1} These show up even more clearly in the 1967 spectra

The strength of this feature seems to be correlated with the total amount of water vapour in the absorbing path and so we tentatively assign it to absorption by a complex molecule containing H_2O^{16}, of which the most likely is the dimer $(H_2O^{16})_2$ We have now started laboratory observations of the absorption of water vapour in the region below 10 cm^{-1} using long absorption paths First results give some support to the solar observations, and we intend to investigate the temperature and pressure dependence of these features

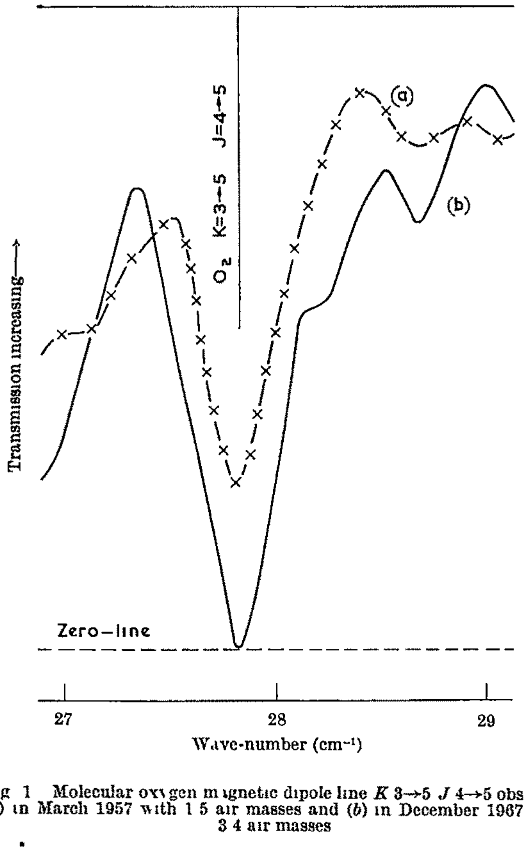

Fig 1 Molecular oxygen magnetic dipole line K 3→5 J 4→5 observed (*a*) in March 1957 with 1 5 air masses and (*b*) in December 1967 with 3 4 air masses

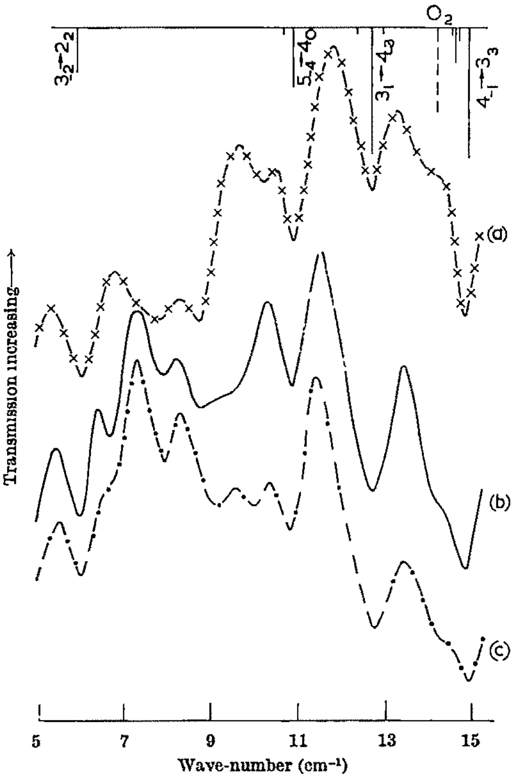

Fig 2 Observed spectrum at 0 5 cm^{-1} resolution of the Sun through the atmosphere (*a*) in March 1957 with 1 5 air masses and 2 mm precipitable water, air temperature +2° C, (*b*) in December 1967 with 3 4 air masses and 3 mm precipitable water, air temperature −26° C, (*c*) with 3 6 air masses and 5 mm precipitable water, air temperature −24° C

The existence of water dimers in atmospheric conditions was predicted by Viktorova and Zhevakin[3], who invoked their presence to explain why higher absorption is observed between the monomer water lines than the strength and shape of the latter would imply These authors also made a numerical prediction, based on a spectroscopic model of the dimer, that there would be an isolated feature at 7 07 cm^{-1} This might at first sight seem gratifying but the numerical values for their molecular constants were derived from the assignment to dimeric water of absorption, at 49 5 cm^{-1}—a feature which was reported by Yaroslavsky and Stanevich[4] We cannot accept that the existence of this line is established, for our own laboratory observations, as well as some recent aircraft observations, show no sign of it at anything like the strength reported in ref 4 We believe that the 49 5 cm^{-1} feature may be an artefact arising from deficiencies of far infrared grating spectrometers The determination of values of molecular constants for dimeric water must therefore await further observation, and assignment

We thank Professor Von Muralt for making available to us the new telescope facility at Jungfraujoch, and Professor M Migeotte, Dr G Roland and Dr L Delbouille for their help

PLANETARY SCIENCE

Measurement of d*T*/dΔ

This communication describes a method of estimating directly the derivative of the travel time curve of seismic body waves, d*T*/dΔ, as a function of epicentral distance Δ, by combining data from several seismometer arrays To test the method the d*T*/dΔ curve for P waves for the range 67°–82° has been estimated The results provide further evidence for rather rapid changes in the velocity gradient in the Earth's deep mantle

The equation of condition for determining the azimuth α, and phase velocity V, of a plane wave crossing an array of n seismometers is

$$C - \frac{R_i \cos(\theta_i - \alpha)}{V} = t_i \qquad (1)$$

where (R_i, θ_i) are the polar co-ordinates of seismometer i (relative to some arbitrary origin), t_i is the arrival time at seismometer i relative to some arbitrary baseline and C is a constant The arrival time t_i will usually be in error, V, α and C can be estimated in the presence of this error by least squares provided n is greater than three The derivative of the travel time curve is then D/V, where D is the number of km per degree of Δ By choosing events at different distances from the array a d*T*/dΔ curve can be constructed Chinnery and Toksoz[1] and Toksoz *et al* [2] have presented d*T*/dΔ curves derived in this way using the Large Aperture Seismic Array, Montana, USA

This method of measuring d*T*/dΔ has the disadvantage that each event must be treated separately so that at each distance there is a scatter of points through which some mean curve must be drawn The method also takes no account of possible effects of structure beneath the array although Chinnery and Toksoz[1] have attempted to minimize this by confining their study to events that lie within a restricted range of azimuth from the array If, however, d*T*/dΔ is determined for a number of events simultaneously the effects of the array structure can be estimated and removed—at least in part—and if the constraint that d*T*/dΔ is constant for all events that fall in the same interval of epicentral distance is applied, the best (least squares) estimate of d*T*/dΔ in each distance interval can be directly obtained The confidence limits on the estimates are also readily obtained

Equation (1) is now rewritten for event j that falls in the kth distance range as follows

$$S_i + C_j - \frac{R_i \cos(\theta_i - \alpha_j)}{V_k} = t_{ij} \qquad (2)$$

where S_i is a correction to the arrival time at seismometer i, and results from the structure at the array site In equation (2), S_i and C_j are linearly dependent so the further assumption that $\Sigma_i S_i = 0$ has to be made By choosing events from a wide variety of azimuths it should be possible to estimate all S_i, C_j, V_k and α_j Because α_j will, however, usually be known fairly accurately from the position of the event epicentre relative to the array site, α_j can be restrained to this known value

Unfortunately, this method is difficult to apply because events are usually poorly distributed in azimuth and distance around any one array To overcome this, data from all four UKAEA designed arrays has been combined The equation of condition now becomes for array h

$$S_{hi} + C_{hj} - \frac{R_{hi} \cos(\theta_{hi} - \alpha_{hj})}{V_k} = t_{hij} \qquad (3)$$

and $\Sigma_i S_{hi} = 0$ for all h

Methods of estimating d*T*/dΔ based on equations (2) and (3) have a further advantage By including the equation of condition

$$\frac{D_1}{V_1} + \frac{D_2}{V_2} \cdot\cdot + \frac{D_k}{V_k} \qquad \frac{D_m}{V_m} = T_m$$

where D_k is the interval in km over which the phase velocity is V_k, the area under the d*T*/dΔ curve can be constrained, if necessary, to what it should be, that is, to T_m, the travel time across the range D_1 to D_m For the results described later, however, application of this constraint has not been necessary

Using data from the arrays at Eskdalemuir (Scotland), Yellowknife (Canada), Gauribidanur (India) and Warramunga (Australia), the d*T*/dΔ curve for P waves for the ranges 67°–82° has been estimated by least squares using equation (3) Eventually this curve will be extended to cover the range 30°–105° but work has been concentrated in the range 67°–82° because of the increasing evidence of rapid changes in the velocity gradient in the deep mantle as revealed by observations in the range 70°–80° Thus Carpenter *et al* [3] using explosion amplitude data show a sharp perturbation in the P wave amplitude–distance curve at around 75° suggesting a possible low velocity layer, and Chinnery and Toksoz[1] and Toksoz *et al* [2] from d*T*/dΔ measurements in the vicinity of 75° conclude that at depths of around 2,000 km the P wave velocity increases much more slowly with depth than normal 67°–82° is therefore an interesting range in which to test the method of measuring d*T*/dΔ described here

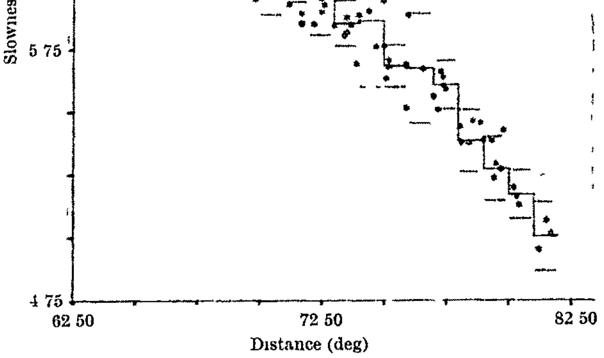

Fig 1 Estimated d*T*/d*Δ* curve for the range 67°–82°
, 95 per cent confidence limits
• d*T*/d*Δ* estimates for individual events using corrected arrival times

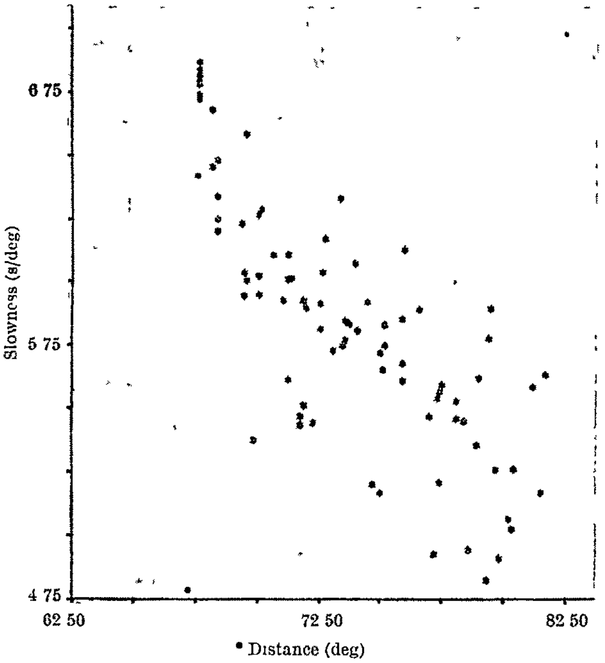

Fig 2 $dT/d\Delta$ estimates for each individual event using uncorrected arrival times

Table 1 and Fig 1 show the $dT/d\Delta$ results and 95 per cent confidence limits for the range 67°–82°, using a total of eighty-four shallow events The $dT/d\Delta$ values estimated for each event individually using the corrected arrival time $t_{hij} - S_{hi} - C_{hj}$ are also shown The arrival times, t_{hij}, were measured by a method proposed by Cleary in a private communication one of the seismometer outputs is taken as standard, the first few seconds of the P phase are traced and the traced curve is matched by eye to each of the other outputs in turn The displacement of the traced curve relative to the standard output is then the arrival time

Fig 2 also shows the $dT/d\Delta$ estimates for each event individually but without applying any corrections for array structure, that is, using equation (1) From a comparison of Figs 1 and 2 it is clear that combining data so that the effects of array structure can be estimated and removed greatly reduces the scatter of the data

The $dT/d\Delta$ curve shown in Fig 1 shows the same inflexion as suggested by Toksoz and Chinnery and is further evidence for anomalous velocity gradients in the deep mantle Detailed comparison of the $dT/d\Delta$ curve and the amplitude–distance curve of Carpenter *et al* [3] has not yet been made but the perturbation in the amplitude–distance curve is consistent qualitatively at least with an inflexion of the $dT/d\Delta$ curve Comparison of travel times and the area under the $dT/d\Delta$ curve shows good agreement The Jeffreys–Bullen time, for example, is 86 40 s and the integral of the $dT/d\Delta$ curve is 86 51 s, a difference of less than 0 2 s This is without any travel time constraints being placed on the $dT/d\Delta$ data These results of the test of the method are thus very encouraging

Inversion of the $dT/d\Delta$ curve to produce a velocity depth structure for the Earth is the ultimate aim of this work The chief purpose of this communication is to describe a method of measuring $dT/d\Delta$ which combines data from a number of arrays and to demonstrate some of the advantages of this method over those that treat each event individually

Two-component Electromagnetic Ship's Log

NAVIGATION on the deep ocean, away from accurate shore-based radio aids, is an important problem for the oceanographer The use of the US satellite navigation system allows accurate position fixes to be obtained at intervals depending on how many satellites are operational, but there remains a need for a system to interpolate between these, particularly when complex manoeuvres are being carried out To fill this need this institute is developing an improved dead-reckoning system, in which the ship's track is calculated from its velocity through the water based on measurement of fore-and-aft speed, sideways speed, or "leeway", and ship's heading An electromagnetic log is available commercially which measures the fore-and-aft speed to an accuracy of about 0 1 knot, but to obtain leeway as well we have developed a new type of electromagnetic log The prototype has been tried successfully at sea, and though full calibration has not yet been possible, there is every indication that an accuracy of 0 1 knot will be obtainable The chief problem in calibration is that account has to be taken of the varying pattern of flow around the hull of the ship for different combinations of fore-and-aft speed and leeway

Apart from its application to finding the ship's position, the new log has been found useful when handling equipment over the side of the ship at low speeds

The principle of operation of the log is shown in Fig 1 A flat coil with a vertical axis and in a streamlined housing is fixed to a spar projecting through the hull of the ship

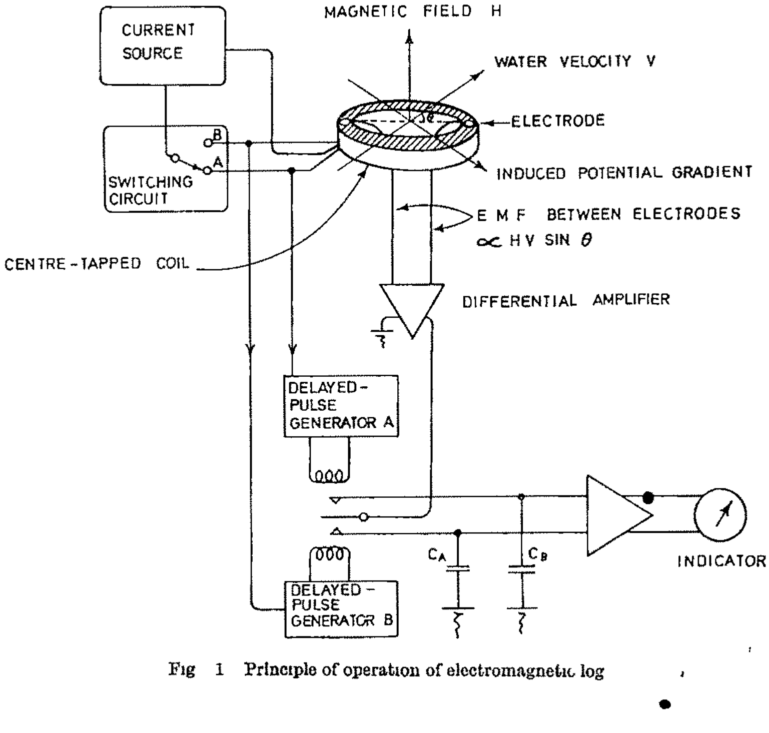

Fig 1 Principle of operation of electromagnetic log

This coil produces a vertical magnetic field, and the water flowing through this field generates a potential gradient perpendicular to both the field and to the direction of flow. Two pairs of electrodes (for simplicity, only one pair is shown in Fig. 1) pick up e.m.fs proportional to the fore-and-aft and athwartships components of the potential gradient, and these e.m.fs are therefore proportional to the athwartships and fore-and-aft components, respectively, of the water velocity past the measuring head.

With a direct current through the coil, the e.m.f. between the electrodes consists of a component caused by the water flowing through the magnetic field, together with components from other sources such as electrochemical effects between the electrodes. If the magnetic field is reversed, the former component is also reversed but the others are unaffected. The electronic circuit therefore measures the change of e.m.f. between the electrodes when the magnetic field is reversed. To reverse the magnetic field it is convenient to use a centre-tapped field coil and to switch the current from one half of the coil to the other.

The reversal of the magnetic field induces transient voltages in the electrode circuit, and the sampling of the e.m.f. between the electrodes is therefore delayed until these have died away. Referring to Fig. 1, and considering the sequence starting with the current switched to coil A, an interval is allowed for the transients to die away and the delayed-pulse generator A then connects the amplifier output to capacitor C_A, which charges to a voltage proportional to the e.m.f. between the electrodes. The amplifier output is then disconnected and the coil current switched to coil B. After the correct interval, the delayed-pulse generator B connects the amplifier output to capacitor C_B. Both capacitors remain at constant potential when disconnected from the amplifier, so that the difference in their potentials is proportional to the component in the electrode voltage caused by the water flow. This difference in potential is amplified and can, for example, be displayed on a meter calibrated in terms of water velocity. The switching is carried out at a rate of about 8 Hz.

Previous electromagnetic flowmeters have used sinusoidal a.c. for energizing the coil, but then it is difficult to prevent spurious e.m.fs from being induced electromagnetically and electrostatically into the electrode circuit, causing a zero offset which has to be balanced out and which can be a source of zero drift. In our device the shape of the measuring head has to be such that the wanted e.m.fs produced (approximately 75 μV knot^{-1}) compared with the voltage (10 V) and current (1 A) in the energizing coil are considerably smaller than in single component logs, so that the directly induced e.m.fs would have presented a serious problem if, say, 50 Hz a.c. had been used. Our measuring system overcomes this effect, and if the zeros of the amplifiers are set with the coil de-energized, the shift in zero when the power is switched on to the coil is too small to detect.

PHYSICS

Surface Energy and Evaporation Rate of Spherical Particles of Radii less than 500 Å

THE vapour pressure of both liquid and solid particles is expected, on thermodynamic grounds, to differ from that of the bulk material. Investigations of the increased vapour pressure for spherical particles have been mainly limited to liquid droplets of a radii greater than 500 Å (see, for example, refs. 1 and 2). The only investigation of solids involving very small particles seems to be that by Pruz[3] (particle diameters 500 Å), who used a radioactive weighing technique to determine the mass loss at 840° K. He obtained a value for the mean surface energy of silver of 6,000 ergs cm^{-2} which is about six times the value found by Udin[4] from the creep of silver at high temperatures.

Simple kinetic theory shows that the vapour pressure of a spherical particle is related to the rate of change of drop radius r with time t by the following equation

$$\left(\frac{\mathrm{d}r}{\mathrm{d}t}\right)_r = \mathrm{const}\, p_r/T^{\frac{1}{2}} \tag{1}$$

where T is the temperature of the drop and p_r the vapour pressure of a drop of radius r. This relation is substituted into the Kelvin equation

$$p_r = p_\infty \exp\left[\frac{2\sigma M}{\rho R T r}\right] \tag{2}$$

where ρ is the density, M the molecular weight, R the gas constant per mole, and T the absolute temperature. For liquids, σ will be the surface tension; for solids with a spherical surface σ will be the surface energy per unit area. It then follows from (1) and (2) that

$$\left(\frac{\mathrm{d}r}{\mathrm{d}t}\right)_r = \left(\frac{\mathrm{d}r}{\mathrm{d}t}\right)_\infty \exp\left[\frac{2\sigma M}{\rho R T r}\right] \tag{3}$$

This equation can be integrated to give the following relation between the radius and the time

$$\Delta t = \frac{2\sigma M}{\rho R T \left(\frac{\mathrm{d}r}{\mathrm{d}t}\right)_\infty}\left[\Delta E_0\left(\frac{2\sigma M}{\rho R T r}\right) - \Delta E_1\left(\frac{2\sigma M}{\rho R T r}\right)\right] \tag{4}$$

where

$$E_0(x) = \left[\frac{\exp(-\mu)}{\mu}\right]_x^\infty$$

and

$$E_1(x) = \int_x^\infty \frac{\exp(-\mu)\,\mathrm{d}\mu}{\mu}$$

Experiments have shown that the variation of drop radius with time is consistent with equation (2), and this variation can therefore be used to determine surface energies. The substances examined were liquid lead, liquid bismuth and solid silver.

The specimens were produced *in situ* in an electron microscope by depositing material on to a carbon substrate maintained at a temperature which gave a convenient evaporation rate. Selected particles were then photographed at regular intervals until they vanished. In order to use the theory it was necessary to ensure that the particles were spherical. Preliminary experiments showed that in suitable experimental conditions there was no difficulty in obtaining spherical liquid drops. In the case of silver spherical particles were produced at a temperature in the region above 1,040° K in agreement with the work of Sundquist[5,6]. Electron diffraction patterns taken *in situ* confirmed that these spherical particles consisted of crystalline silver.

Results for typical experiments are shown in Figs. 1*a* and *b*. In both cases the continuous curve is that obtained from equation (4). The value of σ for lead is that for massive liquid at this temperature. For bismuth, very similar curves were obtained at $T = 677°$ K with $\sigma = 374$ dynes cm^{-1} (which is the value for the massive liquid).

For silver, good agreement is obtained with theory with $\sigma = 1{,}130$ ergs cm^{-2} at 1,045° K. This value is the

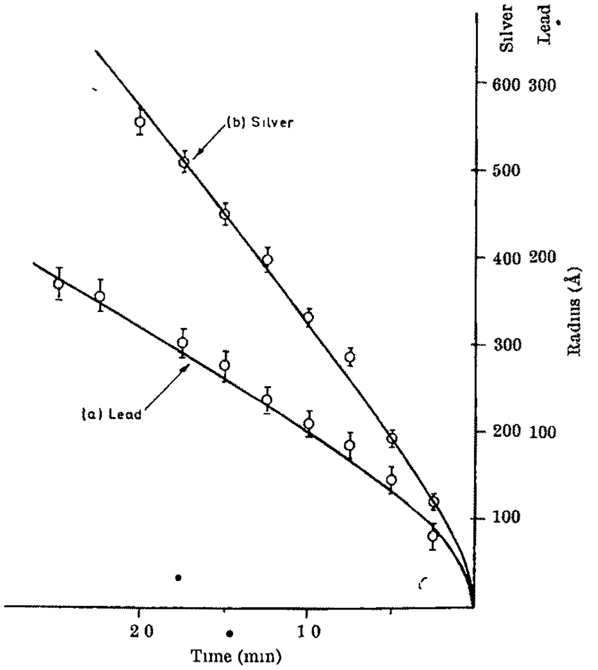

Fig 1 *a*, The evaporation of lead droplets as a function of time, $\sigma = 434$ dynes cm^{-1}, $T = 726°$ K *b*, The evaporation of spherical silver particles as a function of time, $\sigma = 1,130$ ergs cm^{-2}, $T = 1,045°$ K The origin of the time axis is chosen so as to coincide with the time of disappearance of the particles

same as that found by Udin[4] at roughly the same partial pressure of oxygen, but at a higher temperature, 1,200° K While the variation in σ caused by this temperature difference is not expected to be large, it should be noted that grain boundary effects are significant in the experiments of Udin, whereas the work presented here refers to single crystals possessing a spherical surface

An examination of the errors associated with the experiment show that the values quoted above are subject to an error of about ± 10 per cent Further experiments are being carried out with the aim of reducing the error and also to study particles of smaller diameter

Nucleation of Freezing in Supercooled Water by Cavitation

Nucleation of freezing in supercooled liquids by cavitation has been ascribed to a momentary large increase in the degree of supercooling, induced by the high transient pressures generated by a collapsing cavity This is a plausible mechanism for substances which contract on freezing, for substances such as water, which expand on freezing, it seems less satisfactory[1] Hickling[2], however, has proposed that the pressures associated with cavitation in water are sufficient to stabilize one of the high-pressure modifications of ice Nuclei of these high-pressure forms presumably transform to ordinary ice as the pressure decays, and nucleate freezing of the bulk liquid occurs

Hickling assumed that compression during cavitation is a reversible adiabatic process Hunt and Jackson[3] have questioned this assumption on the grounds that the process should be irreversible, more nearly resembling a shock wave compression They have calculated an incremental temperature increase caused by this irreversibility, and conclude that the liquid phase is stable in all states accessible by a shock compression of water from an initial state at 0° C and 1 atm , thereby implying the impossibility of Hickling's proposed mechanism for nucleation

Hickling[4] has defended his assumption of reversibility The purpose of this communication is to show, however, that this assumption is not critical, and that Hunt and Jackson's objection is probably not valid Their calculation of the temperature rise in water during shock wave compression does not agree with the results of other studies of this problem, and there is indeed experimental evidence for a phase transition in water as a result of shock wave compression

There is still some uncertainty concerning the relationships between pressure, volume, and temperature for water at high pressures Several calculations of the temperature rise along the Hugoniot curve (the locus of all states accessible by shock wave compression from a given initial state) give somewhat different results For example, Kirkwood and Montroll[5,6] in an early theoretical study predicted that the Hugoniot curve for water centred at an initial state at 20° C and 1 atm would cross the equilibrium curve between liquid water and "Ice VII" at about 25 kbar The solid phase was predicted to be stable at all higher pressures Their calculation was based on data from static high-pressure investigations of the water–ice system A more recent study by Rice and Walsh[7] agrees with Kirkwood and Montroll's work at lower pressures, but predicts somewhat higher temperatures at higher pressures The primary data in Rice and Walsh's calculations were

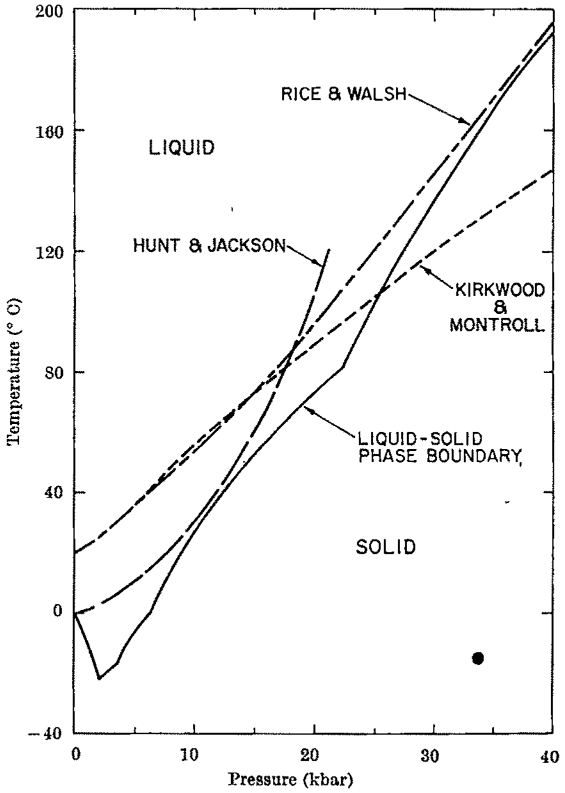

Fig 1 Hugoniot curves of Rice and Walsh, Kirkwood and Montroll, and Hunt and Jackson, superimposed on a plot of the solid–liquid phase equilibrium curve for water

P-V data from shock wave compression experiments, temperatures were derived by making simplifying assumptions concerning the specific heat of water at high pressures In view of these differences, the Hugoniot curves of Rice and Walsh and of Kirkwood and Montroll are superimposed on a P-T plot of the liquid–solid equilibrium line of water in Fig 1, along with Hunt and Jackson's results It is obvious that a displacement of either Kirkwood and Montroll's or Rice and Walsh's Hugoniot curves to an initial temperature of 0° C or below would predict stability of the solid phase from 20–25 kbar to much higher pressures Hunt and Jackson's curve deviates strongly from the others as pressure increases In the absence of more detailed information concerning their calculation, it is difficult to ascertain the reasons for this lack of agreement

Experimentally, Walsh and Rice[8] found no evidence for a phase transition during shock compression of water to pressures up to 100 kbar Al'tshuler, Bakanova, and Trunin[9], however, have reported both optical and hydrodynamic evidence for a phase transition at 115 kbar Unfortunately, they did not specify their initial temperature. Because the positions of both the liquid–solid equilibrium curve and the Hugoniot curve are not known at these pressures, one cannot estimate the degree of transient supercooling in their experiments Nevertheless, it is clear that the Hugoniot curve does cross the phase equilibrium line, and that transient high pressures can induce nucleation

Hickling and Plesset[10], using a numerical model, have estimated the peak pressures to be expected from cavity collapse in water Their values range from several tens to several hundred kbar, depending on the amount and thermal behaviour of the gas in the cavity The inclusion of real gas effects at high temperatures usually gave rise to the higher peak pressures It therefore seems that Hickling's proposed mechanism for nucleation of freezing in supercooled water by cavitation cannot be dismissed on the grounds cited by Hunt and Jackson

New Mounting for Concave Grating Spectrometers

A METHOD has been devised for designing an X-ray spectrometer which requires no movement of the grating or the electronic counter Spectrometers widely used in the past have contained a fixed light source and a movable counter The development of sensitive electronic counters with delicate and complex cooling systems makes movement of the counter undesirable Our mounting makes it possible to use a fixed counter, and spectra can be obtained using a multiple-channel-scalar or displayed on a Braun tube directly

In Fig 1, X-rays radiating from a point source $F(\rho,\varphi)$ are diffracted by a grating G of radius R and focused at a point $S(r,\theta)$ We have $d(\cos\varphi-\cos\theta)=n\lambda$, where d, λ and n are the grating constant, the wavelength and the spectral order, respectively

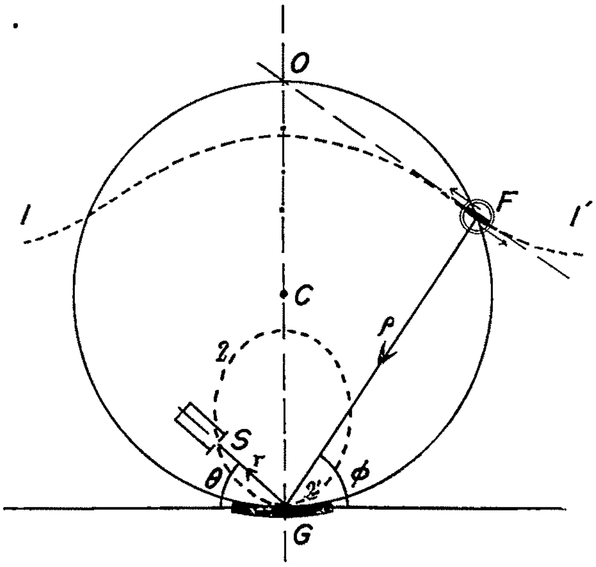

Fig 1 Principle of the Sawada mounting for a concave grating spectrometer *C*, Centre of Sawada circle, *G*, grating, *F*, X-ray tube provided with a cathode-ray deflector, *S*, slit of an electronic counter

We can determine the direction of the diffracted beams by the grating equation, and the magnitudes of the vectors[1–3] of the incident and diffracted beams can be determined by the following two conjugate equations

$$\frac{\sin^2\varphi}{\rho}-\frac{\sin\varphi}{R}=-\frac{1}{D}$$

$$\frac{\sin^2\theta}{r}-\frac{\sin\theta}{R}=\frac{1}{D}$$

where D is a parameter When D is infinite, the two equations reduce to a single self-conjugate circle—the Rowland circle If D has any other value, the (r,θ) curve becomes an oval, and its conjugate (ρ,φ) curve becomes W-like or omega-like, having two asymptotes and two inflexion points The shortest distance from the mid-point of the grating G to a point on the (ρ,φ) curve lies in the direction given by $\sin\varphi=2R/D$, where $D>2R$ It also lies on the circumference of a circle $\rho=2R\sin\varphi$, the centre of which is at C, and which has a radius that of the grating itself We will tentatively refer to this circle as the Sawada circle If we put an X-ray source $F(\rho_0,\varphi_0)$ on the Sawada circle and scan this source back and forth along a straight line which is a tangent at F to the curve (1–1′), described by

$$\rho=R\sin^2\varphi/[\sin\varphi-(\tfrac{1}{2})\sin\varphi_0]$$

so that the scanning direction lies on the straight line perpendicular to the vector GF, then the diffracted spectra are always at the slit $S(r_0,\theta_0)$ of the counter, the co-ordinates of which are

$$r_0=R\sin^2\theta_0/[\sin\theta_0+(\tfrac{1}{2})\sin\varphi_0]$$

This point lies on the curve (2–2′) in Fig 1

A comparison of the astigmatic and spherical aberrations[4,5] between the Sawada and the Rowland cases gives

$$^{S}E_{ast}-{}^{R}E_{ast}=\frac{l^2}{4R}\;\frac{\sin^2\varphi-\sin^2\theta}{\sin^2\theta\sin\varphi}$$

and

$$^{S}E_{spher}-{}^{R}E_{spher}=\frac{(w^2+l^2)^2}{8R^2}\;\frac{\sin^2\varphi-\sin^2\theta}{\sin^2\theta\sin\varphi}$$

where w and l are the width and length, respectively, of the rulings measured from the centre of the grating These expressions show that in the positive spectral orders the astigmatic and spherical abberations are small for the Sawada mounting compared with the Rowland mounting Another merit of the Sawada mounting is that the total optical path lengths are practically constant compared with the Rowland mounting, so that cumbersome intensity corrections can be avoided

Measurement of Normal Stress Differences in Solutions of Macromolecules

THE measurement of normal stress differences generated in the steady laminar shearing motion of solutions of macromolecules has attracted a great deal of attention[1] The experimental work has been performed almost exclusively at low shear rates using three well known flow geometries the concentric cylinder, parallel plate and the cone and plate geometry The use of these three curvilinear geometries has been described in detail elsewhere and the current position is that determination of the three normal stress differences (usually labelled $p11-p22$, $p22-p33$, $p33-p11$) involves the use of more than one shearing geometry[1]

Recently I introduced the ring and plate geometry[2], which readily enables the medium range of shear rates to be investigated An outline of the arrangement, modified to include the central capillary tube to allow normal stress measurements to be obtained, is shown in Fig 1

In the original work the ring width (r_2-r_1) was adjusted so that with a mean ring radius of about 1 in the variation of shear rate over the ring surface was 10 per cent With a gap between ring and plate of 0 001 in mean shear rates of 40,000 s^{-1} were attained without much difficulty using the geometry in the Weissenberg rheogoniometer This shear rate is well within the range of industrial significance

The introduction of a capillary tube in the upper platen as shown in Fig 1 allows the pressure of the fluid within the region $0 \leqslant r \leqslant r_1$ to be sensed The corresponding normal force between the ring and plate over this same interval is

$$F_1 = \rho g \pi r_1^2 \Delta h \qquad (1)$$

where ρ is the density of the fluid in the capillary tube and Δh is the increment in the meniscus height from the undisturbed state at zero shear rate There will also be a contribution caused by centrifugal effects but we assume for the moment that these are small enough to be neglected, although the effect can easily be incorporated

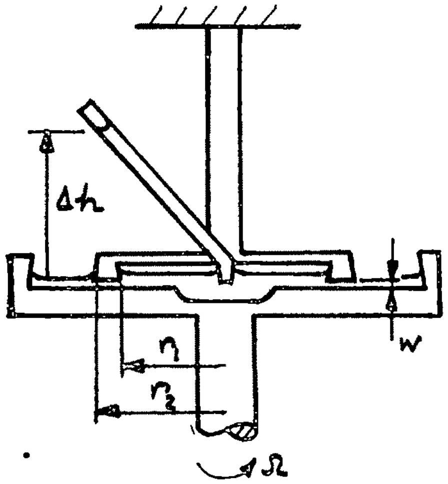

Fig 1 The ring and plate geometry.

If F is the total normal force between the ring and plate, then the force on the ring alone is

$$F_2 = F - F_1 \qquad (2)$$

and this is experimentally determinable (For example, by using the Weissenberg rheogoniometer)

At $r=r_1$ the radial stress in the material in the sheared annulus is

$$-(\widehat{rr})_1 = \rho g \Delta h \qquad (3)$$

Neglecting centrifugal effects again, the radial equation of equilibrium within the annulus is

$$\frac{\partial \widehat{rr}}{\partial r} + \frac{\widehat{rr} - \widehat{\theta\theta}}{r} = 0 \qquad (4)$$

where $\widehat{\theta\theta}$ is the normal stress in the circumferential direction at the radius considered

The shear rate within the annulus is given by

$$\gamma = \frac{\Omega r}{w} \qquad (5)$$

where Ω is the (steady) relative rate of rotation of the plates

Equation (4) can be integrated

$$-(\widehat{rr})_1 = \int_{r_1}^{r_2} \left(\frac{\widehat{\theta\theta} - \widehat{rr}}{r} \right) \mathrm{d}r \qquad (6)$$

The radial stress at $r=r_2$ is (nearly) the ambient pressure, here taken as datum

Differentiating equation (6) with respect to the lower limit yields

$$\frac{\partial (\widehat{rr})_1}{\partial \ln(r_1)} = (\widehat{\theta\theta} - \widehat{rr})_1 \qquad (7)$$

where the suffix 1 denotes quantities evaluated at $r=r_1$ Equation (7) represents a normal stress difference—it may be written as

$$(\widehat{\theta\theta} - \widehat{rr})_1 = -\rho g \frac{\partial(\Delta h)}{\partial \ln(r_1)} \qquad (8)$$

The force on the ring alone is

$$-F_2 = \pi \int_{r_1}^{r_2} \widehat{zz}\, \mathrm{d}\,(r^2) \qquad (9)$$

Differentiating equation (9) with respect to the lower limit

$$(\widehat{zz})_1 = \frac{1}{\pi} \frac{\partial F_2}{\partial\, r_1^2} \qquad (10)$$

Hence, combining equations (1), (2), (3) and (10)

$$(\widehat{rr})_1 - (\widehat{zz})_1 = -\rho g \Delta h - \frac{1}{\pi}\left(\frac{\partial F}{\partial {r_1}^2} - \frac{1}{2}\rho g \pi r_1 \frac{\partial(\Delta h)}{\partial r_1}\right) \quad (11)$$

Experiments are required with rings of constant outer radius r_2 and various inner radii r_1.

Equations (8) and (11) are the equations required. A third normal stress difference can, of course, be derived from these two. It seems that this curvilinear flow geometry is unique at the moment because it is capable of yielding all three normal stress differences. Furthermore, by using sufficiently narrow gaps between ring and plate it should be possible to extend greatly the shear rate range beyond those currently attainable with curvilinear flows. The subject of self-alignment of the platens will be dealt with elsewhere.

In experimental arrangements with narrow menisci at the platen perimeters there is the possibility of anisotropic surface tensions developing. It is already known that polymer surface films can exhibit elasticity and it is reasonable to suppose, in accordance with bulk behaviour, that normal surface tensions may develop in simple surface shearing. Accordingly, results which take no account of this possibility should be viewed with some reserve at the moment. In the experimental arrangement in Fig. 1 surface velocity gradients will undoubtedly be very small in comparison with the gradients between the ring and plate and hence surface effects will be minimized.

Dimensional Problem of the Power Law in Rheology

I HAVE discussed points raised in my recent communication[1] with Scott Blair and we think that it may not have been made quite clear that the treatment applied only to certain conservative systems with flow properties which vary with time. It has been applied to two such systems, starch solution[2] and rennetted milk[3]. It is not, of course, possible to isolate three independent parameters from the monotonic flow curve obtained with many systems.

THE SOLID STATE

Grain Boundary Diffusion Effects in Films of Gold on Chromium

SOME interesting and important effects have been observed when gold films are annealed. The films were prepared on borosilicate glass substrates. They were about 4000 Å thick and had underlayers of chromium 100 Å thick. Examination of the film surfaces has shown that certain diffusion effects occur predominantly at grain boundaries. Two distinct phenomena have been observed—the gradual emergence of ridges of materials

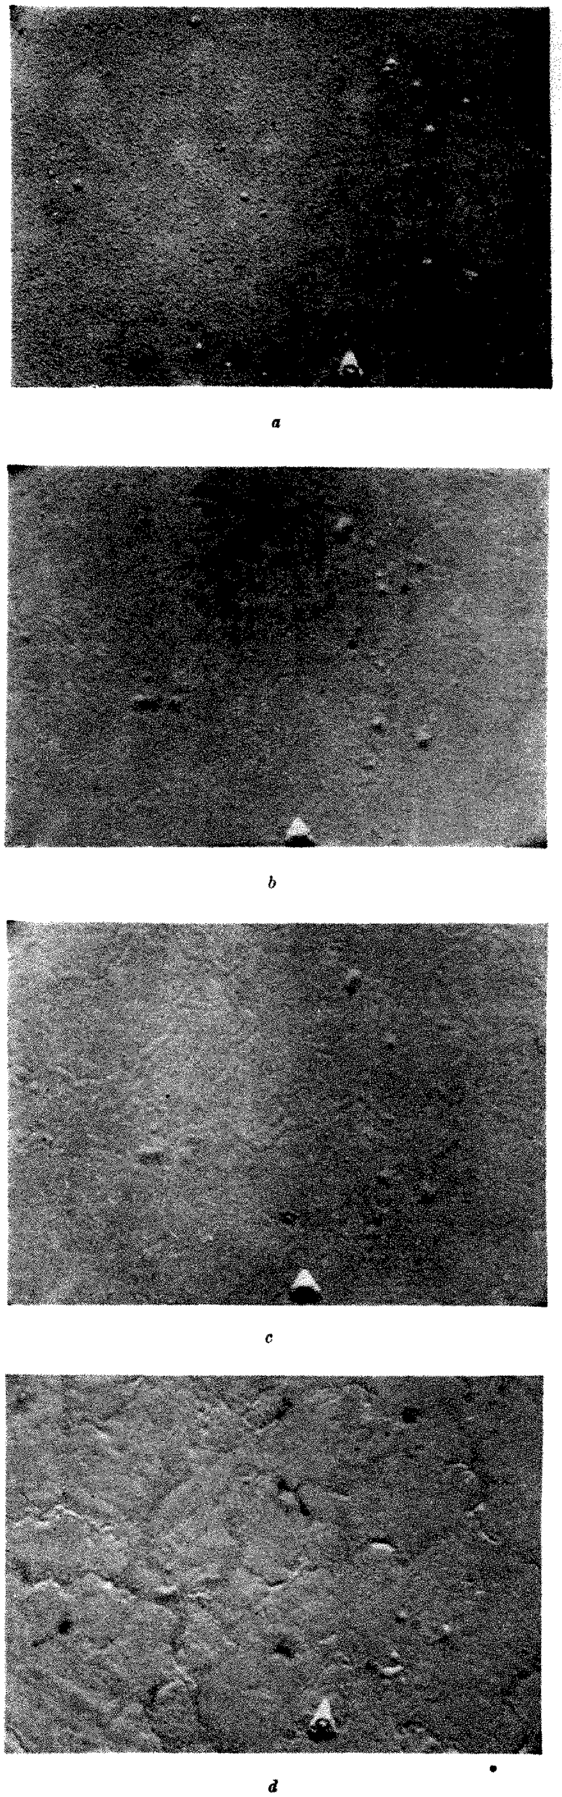

Fig. 1. Effect of annealing at 300° C: (*a*) as deposited; (*b*) after 3 h; (*c*) after 5 h; (*d*) after 11 h. (× 16,500).

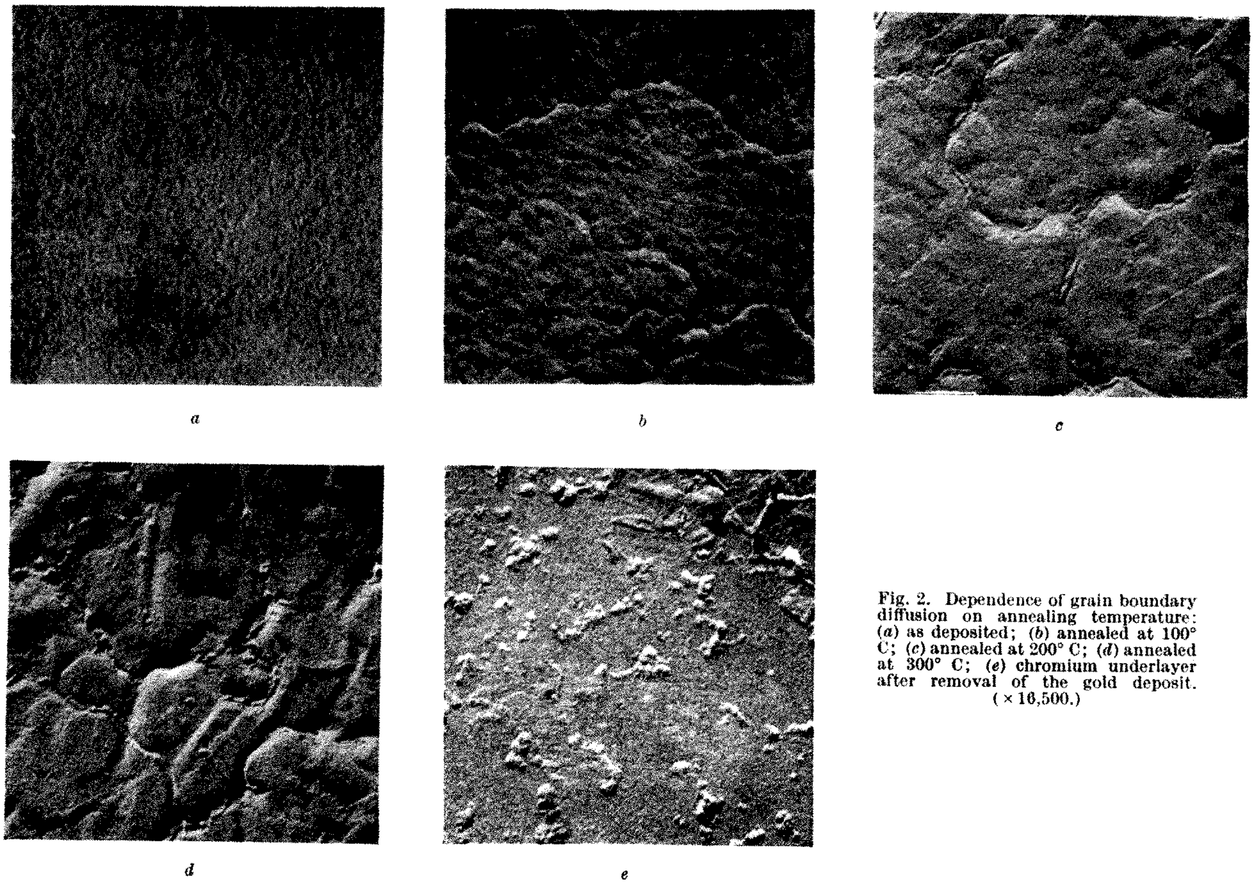

Fig. 2. Dependence of grain boundary diffusion on annealing temperature: (*a*) as deposited; (*b*) annealed at 100° C; (*c*) annealed at 200° C; (*d*) annealed at 300° C; (*e*) chromium underlayer after removal of the gold deposit. (× 16,500.)

decorating the grain boundaries and a more catastrophic change of surface in which the crystallites stand out as islands.

A controlled technique was applied to produce a smooth surface, gold-on-chromium film. The film was then annealed and examined by stages. It was annealed at 300° C, first for 3 h then for a further 2 h and then for a further 6 h. At each stage a collodion carbon replica of a selected area of the surface was prepared and examined in an electron microscope. Fig. 1 shows the micrographs obtained. Fig. 1*a* shows the smooth surface of the original film. After the first annealing, ridges appeared in the surface indicating the positions of grain boundaries (Fig. 1*b*). After successive periods of annealing these became more strongly emphasized.

This film was typical of other gold-on-chromium films produced. Some films were annealed for short periods of time and others for up to 20 h at various temperatures. The crystallites had an average diameter of a few microns which remained constant throughout the annealing treatment. It is thought that the crystallites had grown to this size on deposition: in one case the positions of grain boundaries could be seen in the film as deposited. A film of gold with no underlayer exhibited crystal grains of a similar size when heated to 300° C for 2 h. The grain boundaries showed up as lines on the surface, but were not emphasized by ridges because there was no underlying material present to decorate the boundaries. The series of micrographs in Fig. 2 clearly shows how grain boundary decoration develops as annealing proceeds by 100° C increments. Fig. 2*e* shows the form of the chromium underlayer after the gold film had ultimately been etched away. The material remaining has migrated into lumps and ridges distinctly outlining flat areas of a similar size

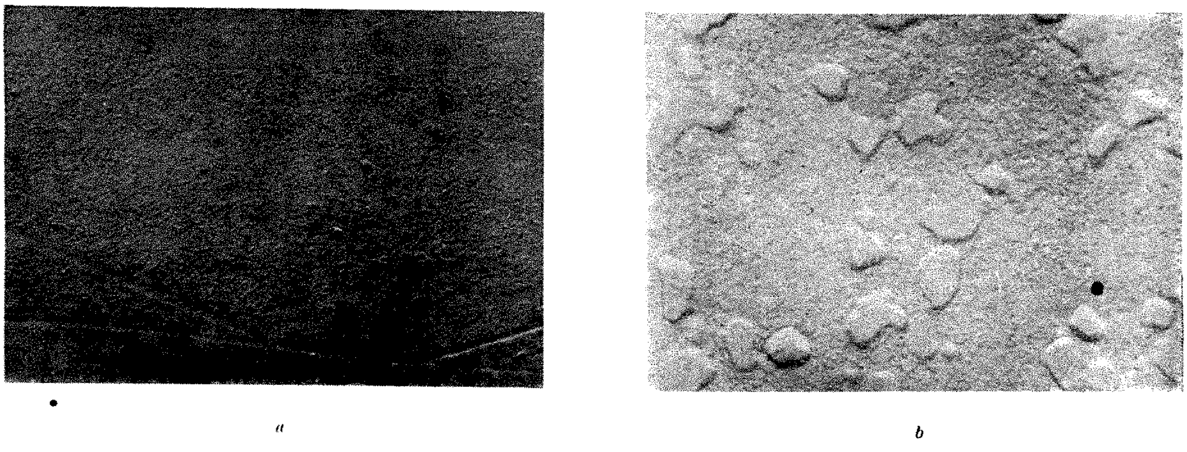

Fig. 3. Violent change of structure: (*a*) as deposited; (*b*) after annealing. (× 16,500.)

to the gold crystallites. This is further evidence that the underlayer material has diffused along the chromium/gold interface and through the gold film between crystal grains.

A more violent effect which occurred with some of the films is illustrated in Fig. 3. The structure of this film including its many scratches had not changed on heating to 100° C for 2 h. But when heated to 200° C, all previous surface features disappeared and were replaced by large crystalline islands. The crystallites were completely free of background texture and stood up about 500 Å from the irregular, original surface level of the film. This effect has occurred in a number of films, but always those which have not exhibited obvious grain boundary diffusion. It is thought that the change may have been initiated by thermal shock because some of the films were seen to turn milky in removal from a hot oven. It has been observed that films deposited fast (30 Å/s) exhibited grain boundary diffusion whereas those deposited more slowly (3 Å/s) underwent a catastrophic change in structure or none at all. This violent change usually followed a succession of severe annealing and replication processes. Another variation in procedure which was found to affect the behaviour of these films on annealing was pre-heating of the substrate. Some substrates were heated under vacuum to 100° C for ½ h and then cooled by means of a water cooled copper block with which they were in contact. Films deposited onto these substrates were very similar in texture to others produced on normal substrates, but on heating the grain boundary structure did not appear. Surprisingly, neither vapour phase mixing of the chromium and gold deposits, nor partial oxidation of the chromium underlayer had any significant effect on the behaviour of the films on annealing.

Certain other underlayer materials have been considered. Iron exhibited an effect very similar to chromium. Reactively sputtered bismuth oxide did not diffuse in the same way although annealing caused a gross surface structure to emerge. Nickel–chromium alloy did not diffuse through overlying gold films but a lumpy surface resulted from the annealing treatment.

Production of Epitaxial Films of Antimony on Disordered Substrates

THERE has been widespread interest in thin films of metals and metalloids during the past decade because of their varied technological and fundamental scientific significance[1-3]. The mechanism of their formation is intimately associated with nucleation theory[4] and epitaxy[1] (the growth of a substance into a single crystal or well oriented polycrystalline form on a different substance as substrate); and their properties are relevant to the study of electrical, magneto-optical and catalytic phenomena[1,5,6]. On the physical side, much effort has been expended in assessing the influence of such factors as the symmetry, lattice spacing and temperature of the substrate in the growth of epitaxial films. On the chemical side, it has recently been recognized that, although evaporated films have greatly stimulated the study of heterogeneous catalysis, the crystallographic heterogeneity of misoriented polycrystalline or amorphous films complicates interpretation of adsorption phenomena, and makes comparison invidious with field ion and other studies which utilize single crystals.

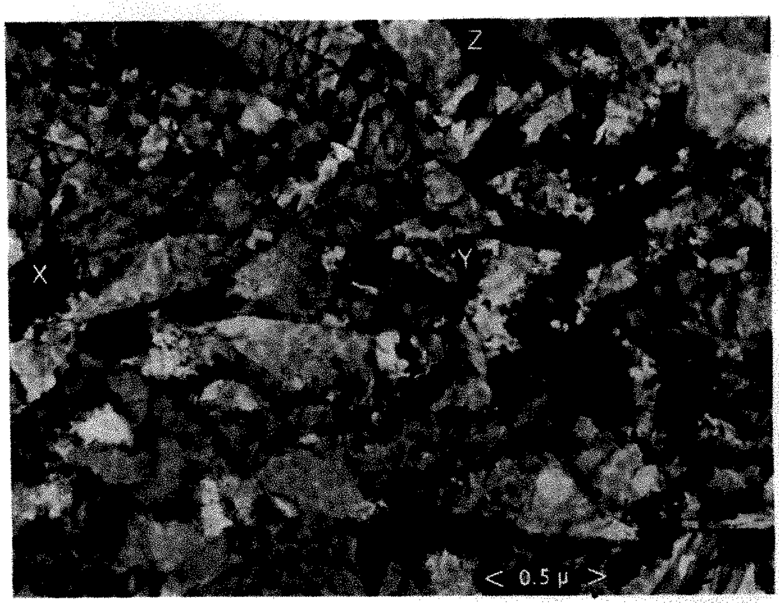

Fig. 1. Transmission electron micrograph of evaporated antimony film (average thickness 1000 Å) showing extinction contours and, in particular, extended dislocation networks in the region marked *XYZ*.

This communication describes the preparation of well oriented evaporated films of antimony in unusual, but readily realizable, conditions, in which the substrate possesses little or no crystallographic symmetry and long-range order, and the substrate temperature is surprisingly low[7]. Some recent speculations[8-10] as to the importance of source material in determining the microstructure of antimony films are tested, together with general statements[11,12] regarding the ease of producing ordered structures on disordered substrates. The results suggest a convenient method of generating single-crystal films of relatively large area suitable for adsorptive studies using low energy electron diffraction[13], work function and related[6] measurements. Together with the work of Yu[12] on the microstructure of films of ionic solids, the results may contribute to the elucidation of certain biochemical processes, especially some aspects of the phenomena recently discussed by Lonsdale[14].

High purity (99·999 per cent) antimony was evaporated from a tungsten spiral in a vacuum of 3×10^{-4} to 5×10^{-5} torr (varied systematically) at an average rate of 30 Å s^{-1} up to a thickness of about 1000 Å. The films were floated off the substrates and examined in transmission using an electron microscope. The temperature of the source was in the range 500°–700° C, and that of the substrate surface, which was 5–6 cm away, never exceeded 30° C during deposition. Three kinds of substrate were used: (1) outgassed 'Pyrex' glass (microscope) slides; (2) 'Pyrex' slides onto which a thin layer of detergent was added, by "rubbing in" a concentrated solution of 'Teepol' and allowing the water to evaporate *in vacuo*, which leaves a waxy film of soap on the glass; (3) collodion mounted on a copper grid for electron microscopy.

Substrates (1) and (2) gave identical results. The films are continuous though of variable thickness, as revealed by the extinction contours (Fig. 1); and the occurrence of an extended dislocation network demonstrates that a remarkable degree of crystalline perfection exists over areas of about 2 μm². Significantly, selected-area diffractions taken from most of the regions shown in Fig. 1 yielded a spot pattern indicative of a single crystal, rather than a well oriented crystalline film, the orientation being such that the {111} planes are parallel to the substrate surface. In a few regions both {100} and {111} orientation occur about equally. Small-angle boundaries, with regions of misorientation up to about 20°, are also present.

With substrate (3) there is again pronounced epitaxy, but there are no signs of dislocation networks, the film readily fragments on floating, and from the diffraction pattern (Fig. 2) it is concluded that a well oriented polycrystalline, rather than a single crystal, film is formed.

When a gold–antimony alloy (atomic ratio Au : Sb = 40 : 60) is used, from which, on heating, monatomic and diatomic as well as the usual tetra-atomic species are vaporized[10], essentially the same results are obtained with substrates (1) and (2) but not with (3), which yields an unoriented polycrystalline film (Fig. 3). Thus the chief differences reported between antimony films produced from the element and from an antimony alloy are not fully repeated here. Aluminium, which has a melting point (660° C) close to that of antimony (631° C) yields a discontinuous polycrystalline film when evaporated to the same thickness on all three kinds of substrate, showing that the ease of oriented growth is not a simple function of melting point.

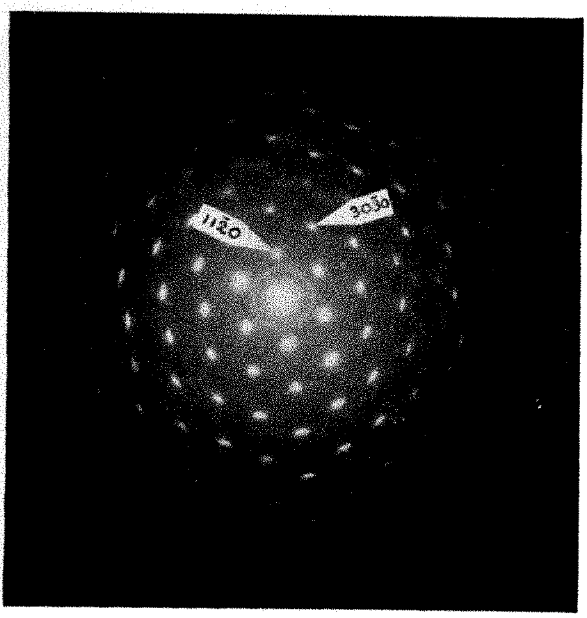

Fig. 2. Selected area diffraction pattern from an area of 15 μm² of a film deposited on collodion.

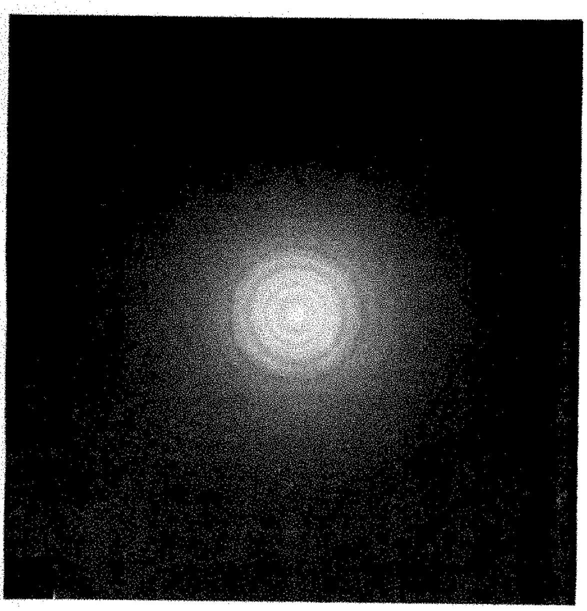

Fig. 3. Diffraction pattern of film deposited from Au–Sb source on a collodion substrate.

It is impossible to decide, as yet, which of the three principal factors—nucleation orientation, growth orientation or recrystallization—known to facilitate the production of epitaxial films dominates here. It is clear, however, that condensed aggregates of antimony formed from gaseous species of varied atomicity are capable of migrating over large distances on non-crystalline surfaces. The highly specific nature of surface migration of metal crystallites on non-metallic, but crystalline, substrates has previously been noted and partly explained[15,16] in terms of Brownian motion.

Preliminary parallel experiments with bismuth indicate that films of this metalloid also show some tendency to be oriented when formed on disordered substrates at very low temperatures.

CHEMISTRY

Heterogeneous Oxidation of Methane over Palladium Catalysts

A brief investigation has been made of the effect of different forms of palladium catalysts on the heterogeneous oxidation of methane. The experiments are based on the idea that, if crystals of metal are formed by thermal decomposition of a metal salt which is deposited within the pore structure of a zeolite, the maximum size to which the metal crystallite can grow is equal to the size of the pore or cavity of the zeolite within which decomposition occurs. Because the dimensions of these cavities and pores are in the range of 0·4–4 nm for most zeolites, it is possible to study catalytic reactions on crystallites of these dimensions without interference from the much larger crystallites present in most supported metal catalysts. These catalysts could be prepared by thermal decomposition of a complex metal salt in which the catalytic metal is in an anionic form so that ion exchange with the zeolite metal ions does not occur. In this study we have compared three catalysts: massive palladium metal (catalyst 1), palladium crystallites within a zeolite structure (catalyst 2) and a zeolite catalyst containing separated metal atoms (catalyst 3) produced in the normal way by ion exchange[1].

Catalyst 1 was prepared by thermal decomposition of an aqueous ammonium chloropalladite solution. The resulting mixture of palladium and palladium oxide was reduced in a 12 per cent methane–air mixture[2] at 900° C. Catalyst 2 was prepared by immersing Linde 13 × molecular sieve in an aqueous solution of ammonium chloropalladite. The sieve was drained, washed with water and dried at 400° C in air. Catalyst 3 was prepared by immersing Linde 13 × molecular sieve in an aqueous solution of tetramminopalladium chloride, prepared by treating ammonium chloropalladite with excess ammonia, draining, washing with water and drying in air at 400° C. Catalysts 2 and 3 contained 3·55 and 0·55 per cent by weight of palladium respectively. Reduction of these two catalysts with hydrogen at 300° C produced a slight increase in activity in catalyst 2 but had no effect on the kinetic results. Poisoning experiments with hexamethyl disiloxane[3] confirmed that in both catalysts 2 and 3 in the prepared and reduced states no metallic palladium was present on the external surface of the zeolite. X-ray diffraction measurements on these catalysts confirmed that catalyst 1 was metallic palladium but failed to detect the presence of palladium in catalysts 2 and 3, indicating that the crystallite size of any metallic palladium in these catalysts was less than about 5 nm.

Methane oxidation over each catalyst was studied by the microcalorimetric method[2]. A large excess of oxygen for complete oxidation to carbon dioxide and water was used in each experiment. The methane pressure range was 0–2 kNm^{-2} and the oxygen pressure range 8–80 kNm^{-2}. Nitrogen was used as a diluent gas to bring the pressure up to 10·1 kNm^{-2}. The zeolite containing no palladium did not oxidize methane in the temperature range studied here. In each case only carbon dioxide and water were detected as reaction products. The relevant kinetic data are given in Table 1.

Table 1. REACTION PARAMETERS FOR METHANE OXIDATION

Catalyst	Form of catalyst	Reaction order in methane	Reaction order in oxygen	Apparent activation energy kJ $mole^{-1}$	Temperature range °C
1	Palladium metal	1	0	50	300–450
2	Palladium in 13 × zeolite. Prepared from ammonium chloropalladite	1	0·3–0·4	50	300–400
3	Palladium in 13 × zeolite. Prepared from palladium ammine	1	0·05	88	300–400

The apparent activation energies were the same on catalysts 1 and 2 but different on catalyst 3, indicating that palladium is present as a metallic phase in catalyst 2 and showing that the presence of the zeolite support in this catalyst does not markedly effect the reaction. The reaction orders indicate that on each catalyst methane is weakly adsorbed and oxyten is strongly absorbed. No negative effect over the ten-fold range in oxygen concentration was observed on any catalyst, which is strong evidence that methane and oxygen are not competing for the same sites on the catalyst. Oxygen, however, is not strongly chemisorbed by zeolites themselves and, because in catalyst 3 the only catalytic sites are the separated palladium ions, such ions are capable of simultaneous adsorption of both oxygen and methane. Moreover, because the complete oxidation of methane requires two oxygen molecules for each methane molecule, the separate palladium ions are able to absorb partially oxygenated methane intermediates as well as oxygen atoms.

The apparent activation energies for the reaction on catalysts 1 and 2 indicate that a similar reaction sequence is occurring on each catalyst and that the bond strengths of the adsorbed intermediates are similar. The decrease in crystallite size in catalyst 2 increases the reaction order in oxygen, however. Such an effect will be produced if the ratio of adsorbed methane to adsorbed oxygen is greater on catalyst 2 than on catalyst 1. This would result in an increase in the rate of creation of vacant adsorption sites by the increased rate of reaction of adsorbed oxygen with adsorbed methane. It is unlikely that this could be caused by cracking of methane by the zeolite itself before adsorption on to the palladium; cracking of methane would result in some oxidation before adsorption, which is contrary to the low order in oxygen on catalyst 3 and the lack of activity for methane oxidation displayed by the zeolites themselves. Palladium metal has a face-centred cubic structure and as the crystallite size decreases the ratio of atoms in the edges of the crystal to those in the faces increases. If methane is adsorbed on the edges of the crystal faces and reacts with oxygen which is strongly adsorbed on the crystal faces and edges, then below a certain crystallite size an increase in the order in oxygen will result. It therefore seems likely that on palladium metal methane adsorption in oxidation reactions occurs at surface imperfections such as steps. Such mechanisms have been proposed for other heterogeneous catalytic reactions[4].

We thank Mr N. J. Cutts for the X-ray diffraction measurements and Mr C. Casswell for helpful discussions.

Stereochemistry of the Allyl Ligand in some Allyl–Palladium Complexes

SEVERAL X-ray analyses of the structures of allyl complexes of transition metal ions have been completed[1]. Apart from the symmetrical bonding found in π-allyl palladium chloride[2,3] and π-allyl palladium acetate[4], the results also indicate considerable changes of the stereochemistry of the allyl group on co-ordination. For example, in both *bis*-π-methallylnickel[5] and triphenylphosphine-2-methallylpalladium chloride[6], the methyl group is bent out of the plane containing the three carbon atoms of the allyl ligand while in π-$C_3H_4.CH_3PPh_3PdCl$[6] and *bis*-π-allyl rhodium chloride[7] the metal–carbon allyl bond lengths are non-equivalent. The very close relation between the bond lengths in these last two molecules rules out the suggestion[8] that the asymmetric allyl to metal bonds are due to "adventitious packing distortions". The non-planarity of the methyl groups in $(\pi\text{-}C_3H_4.CH_3)_2Ni$ and π-$C_3H_4.CH_3.PPh_3.PdCl$ may indicate σ–π electron mixing in the ligand[9] and other methyl-substituted allyl complexes have now been studied to provide further information on this point.

π-2-Methallyl palladium chloride crystallizes in the triclinic system, being the dimeric molecule required to be centrosymmetric in the space group P$\bar{1}$; its geometry is shown in Fig. 1. The methyl groups are displaced 0·3 Å towards the metal from the plane of the allyl–carbon atoms, so that the result noted earlier[6] is not a consequence of asymmetry in the metal–allyl bond. The dihedral angle which the two crystallographically equivalent allyl groups make with the plane containing the palladium and chlorine atoms is 112°. The average estimated standard deviations in the bond lengths are Pd–Cl 0·005 Å, Pd–C 0·018 Å and C–C 0·026 Å ($R = 0{\cdot}078$ for 1,123 independent reflexions).

π-1,1,3,3-Tetramethallylpalladium chloride is also dimeric in the space group P$\bar{1}$. The molecular geometry (Fig. 1) results from a refinement of 1,040 independent reflexions ($R = 0{\cdot}087$). As in the π-2-methallyl complex, the Pd_2Cl_2 bridge system is required to be planar and the dihedral angle of the allyl carbon plane with respect to this plane is 121°. Estimated standard deviations of the bond lengths average 0·007 Å (Pd–Cl), 0·026 Å (Pd–C) and 0·039 Å (C–C).

In both of these molecules the palladium–carbon and carbon–carbon bond lengths in the allyl ligand are identical within experimental error. This result, together with the observed planarity of the Pd_2Cl_2 rings in both structures, makes the reported geometry of the π-1,3-dimethallylpalladium chloride dimer[10] extremely difficult to understand. In the π-1,1,3,3-tetramethallylpalladium chloride dimer, each pair of methyl groups is distorted from the plane of the allyl carbon atoms to produce a conformationally eclipsed arrangement; atoms C4 and C7 are displaced 0·4 Å towards the metal, atoms C5 and C6 being pushed 0·8 Å away from the metal. A simple way of picturing the allyl stereochemistry is that the average deviation of C(1,3) from the plane containing C2, C(5,6) and C(4,7) is 0·2 Å; if C1 and C3 were trigonal, this deviation would be zero, whereas if they were tetrahedral it would be approximately 0·5 Å.

π-1,1,3,3-Tetramethallyltriphenylphosphine palladium chloride has also been investigated to determine whether the deviation of C1 and C3 from trigonal stereochemistry depends on the symmetry or otherwise of the metal–ligand bond. The refinement is not yet complete (the present discrepancy index is 0·097) but it can be stated that the methyl groups are again displaced from the allyl plane to give a conformationally eclipsed structure, the average deviations of the two pairs of methyl carbon atoms being −1·2 Å and +0·4 Å.

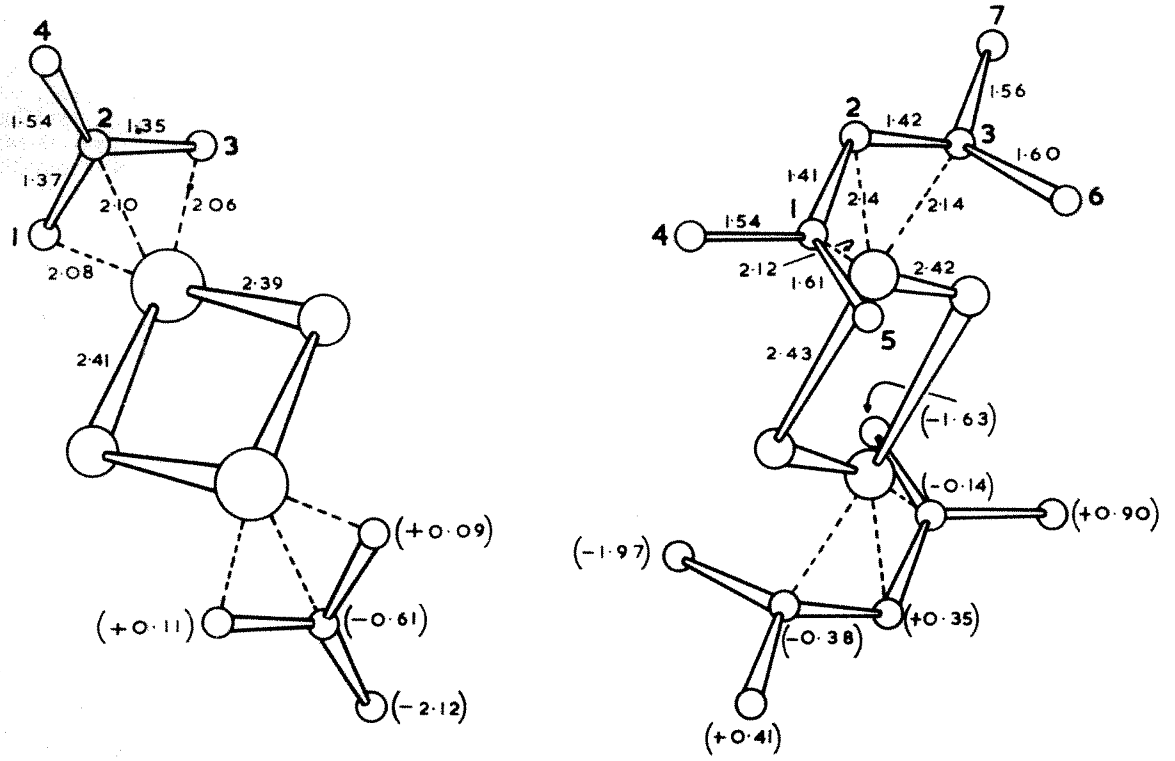

Fig. 1. The molecular geometries of the π-2-methallyl palladium chloride and the π-1,1,3,3-tetramethallyl palladium chloride dimers. Numbers in parentheses refer to deviations (Å) of carbon atoms from the Pd_2Cl_2 planes.

We thank Dr B. L. Shaw and his colleagues for samples of these allyl complexes and the E.I. Dupont et Nemours Company and the Science Research Council for financial support.

Influence of Carbon Dioxide in the Calcite–Sodium Oleate Flotation System

FATTY acids are usually employed in the flotation of carbonate minerals as collectors; among them oleic acid in the form of sodium oleate is important. Mortenson and Ljøkjell[1] reported that flotation of calcite using sodium oleate as the collector is improved by conditioning the pulp with carbon dioxide. Biswas[2] pointed out that the improvement due to the use of carbon dioxide is not related solely to the lowering of *p*H but is largely attributable to the surface chemical reaction in the system. We report further studies on this system.

To study the calcite–carbon dioxide–water system transparent calcite crystals were wet ground and sieved. About 20 g of moist samples of $-120+140$ ASTM mesh size range were treated with 150 ml. of distilled and deionized water in a 500 ml. reagent bottle and then carbon dioxide was bubbled through the system for various times at a constant rate of 3 l./min. The bottle was shaken for 30 min and kept in a thermostat (operating at 30 ± 0·1° C) for 1 h. For each set, the slurry was filtered and the Ca^{++}, $CO_3^=$ and HCO_3^- concentrations in the filtrate estimated.

Calcium estimation was done by the ammonium purpurate method described by Williams and Moser[3]. The *p*H was maintained at 11·3 and percentage absorbance was measured at 505 mμ. It was established that neither carbon dioxide nor sodium oleate interferes with the estimation of calcium by this method. Carbonate and bicarbonate were estimated by titration[4]; the results are presented in Table 1.

Table 1. CALCITE–CARBON DIOXIDE–WATER SYSTEM

Time of bubbling of carbon dioxide at the specified rate (min)	Carbonate (moles/l.)	Bicarbonate (moles/l.)	Calcium (moles/l.)	$[Ca^{++}][CO_3^=]$	*p*H at the end of the experiment
0	$2{\cdot}87\times10^{-3}$	—	$0{\cdot}19\times10^{-3}$	$54{\cdot}5\times10^{-8}$	7·26
5	$0{\cdot}10\times10^{-3}$	$1{\cdot}26\times10^{-3}$	$1{\cdot}56\times10^{-3}$	$15{\cdot}6\times10^{-8}$	—
10	$0{\cdot}18\times10^{-3}$	$1{\cdot}17\times10^{-3}$	$2{\cdot}30\times10^{-3}$	$41{\cdot}4\times10^{-8}$	—
20	$0{\cdot}20\times10^{-3}$	$0{\cdot}16\times10^{-3}$	$3{\cdot}35\times10^{-3}$	$67{\cdot}0\times10^{-8}$	5·56
30	$0{\cdot}13\times10^{-3}$	$0{\cdot}12\times10^{-3}$	$3{\cdot}48\times10^{-3}$	$45{\cdot}2\times10^{-8}$	5·80

To study the calcite–carbon dioxide–sodium oleate–water system a similar set of experiments was performed with moist calcite immersed in 100 ml. of sodium oleate solution of known concentration and the procedure already described was followed.

In this set of experiments, estimations of sodium oleate and calcium ion were made at different stages. A method of colorimetric estimation of sodium oleate using Nile blue as the complexing reagent was developed on the basis of earlier findings by Goiffin and Conchand[5]. It was necessary to buffer the solution at *p*H 11·2. Colorimetric estimation at a wavelength of 620 mμ was found to be unaffected by the presence of carbon dioxide. Presence of carbon dioxide was found not to interfere with the estimation of sodium oleate. The data obtained are given in Table 2. These results suggest the following.

(*a*) As more carbon dioxide is bubbled through the calcite suspension, the concentrations of Ca^{++} and HCO_3^- in the solution increase, presumably as a result of a surface chemical reaction. The equilibrium constant values for the various dissociative reactions in this system were worked out by Garrels and Christ[6]. According to them, if a calcite suspension is equilibrated with pure water without any gas such as carbon dioxide, the ionic concentration values should be $0{\cdot}126\times10^{-3}$, $0{\cdot}398\times10^{-4}$ and $0{\cdot}891\times10^{-4}$ moles/l. for Ca^{++}, $CO_3^=$ and HCO_3^-, respectively. It should be pointed out that, according to Mellor[7], the solubility of $CaCO_3$ is 0·0014 g/100 ml. of water at 25° C and thus the concentration of Ca^{++} at equilibrium should be $0{\cdot}14\times10^{-3}$ moles/l. Our data reported in Table 1 ($0{\cdot}19\times10^{-3}$ moles/l.) is slightly higher. Garrels and Christ[6] further postulated on the basis of equilibrium constants that equilibration with atmospheric air containing carbon dioxide (partial pressure $10^{-3.5}$) would raise the concentrations of Ca^{++} and HCO_3^- to $0{\cdot}398\times10^{-3}$ and 10^{-3} moles/l., respectively, and lower the carbonate concentration to $0{\cdot}126\times10^{-4}$ moles/l. These trends are reflected and established in data presented in Table 1. The value for the ionic concentration product $[Ca^{++}]$ $[CO_3^=]$, however, was not constant in the experimental conditions, and differs widely from the theoretical value: $0{\cdot}2\times10^{-8}$. This inconstancy and discrepancy reflect non-attainment of equilibrium conditions.

Table 2. CALCITE–CARBON DIOXIDE–SODIUM OLEATE–WATER SYSTEM

Initial concentration of sodium oleate solution: $9{\cdot}85\times10^{-4}$ moles/l.

Time of bubbling of carbon dioxide at the specified rate (min)	0	5	10	20	30
Concentration of calcium (moles/l.)	$0{\cdot}32\times10^{-3}$	$0{\cdot}66\times10^{-3}$	$1{\cdot}02\times10^{-3}$	$1{\cdot}71\times10^{-3}$	$2{\cdot}49\times10^{-3}$

Time of bubbling of carbon dioxide (min)	Final concentration of oleate (moles/l.)	Amount of oleate adsorbed (moles/g)
Initial concentration of sodium oleate solution: $2{\cdot}35\times10^{-4}$ moles/l.		
0	$1{\cdot}61\times10^{-4}$	$0{\cdot}41\times10^{-6}$
5	$0{\cdot}54\times10^{-4}$	$1{\cdot}04\times10^{-6}$
10	$1{\cdot}74\times10^{-4}$	$0{\cdot}39\times10^{-6}$
Initial concentration of sodium oleate solution: $4{\cdot}70\times10^{-4}$ moles/l.		
0	$1{\cdot}13\times10^{-4}$	$2{\cdot}20\times10^{-6}$
5	$0{\cdot}52\times10^{-4}$	$2{\cdot}72\times10^{-6}$
10	$0{\cdot}89\times10^{-4}$	$2{\cdot}30\times10^{-6}$
Initial concentration of sodium oleate solution: $9{\cdot}40\times10^{-4}$ moles/l.		
0	$1{\cdot}02\times10^{-4}$	$5{\cdot}35\times10^{-6}$
5	$3{\cdot}03\times10^{-4}$	$3{\cdot}94\times10^{-6}$

(*b*) Even in the presence of sodium oleate, this surface chemical reaction mentioned is evident. The concentration of calcium in the solution increases as more carbon dioxide passes (Table 2). The slower increase in calcium concentration could be caused by an adsorbed layer of oleate hindering the diffusion of carbon dioxide or by the parallel precipitation reaction which results in the formation of calcium oleate.

(*c*) Adsorption of sodium oleate on calcite increases with a greater initial concentration of sodium oleate and with the use of a limited amount of carbon dioxide. With more carbon dioxide, however, a process of desorption is initiated.

The difference in the adsorption of oleate on calcite in the carbonated and uncarbonated pulp is pronounced for low concentrations of sodium oleate, for example, $2{\cdot}35\times10^{-4}$ moles/l. For a high concentration such as $9{\cdot}4\times10^{-4}$ moles/l., adsorption actually decreases with the use of carbon dioxide.

(*d*) Thus it seems plausible that bubbling a limited amount of carbon dioxide increases the concentration of the calcium in the solution through surface chemical reaction, which in turn induces heightened adsorption of collector (oleate) and increases flotability. The beneficial effect of carbon dioxide (in terms of collector adsorption and flotation) is discernible only at low collector concentration[2].

BIOCHEMISTRY

Recognition of DNA Base Sequence Differences among Vertebrates

UNLIKE the wide variation of DNA base composition found in bacteria, higher organisms tend to have a restricted average base composition (vertebrates ~42 moles per cent guanine + cytosine)[1]. Thus physical methods such as thermal denaturation or equilibrium density gradient sedimentation, which are useful in distinguishing bacterial DNAs[2], do not discriminate to any extent among vertebrate DNAs, excluding the question of satellite bands. Phylogenetic relationships among bacteria, based on other criteria, are largely borne out by DNA–DNA hybridization[3]. While the latter technique can discriminate among distantly related higher organisms[4] it can be applied with only limited confidence to more closely related vertebrates.

Another approach is to fractionate single strands of DNA according to base sequence and to compare the resulting fractions. One method presently available for fractionation of DNA strands is countercurrent distribution[5] in solvent systems different from those used for sequence-dependent fractionation and purification of transfer RNA species[6]. Countercurrent distribution of single-stranded DNA shows a base composition gradient, with guanine-rich fractions more soluble in the aqueous (lower) phase and adenine-rich fractions more soluble in the organic (upper) phase[5]. The relation between secondary structure and the behaviour of double-stranded DNA in the same solvent systems[7,8] indicates that partition of DNA in these systems is dependent on the availability of free amino groups. This observation, the varying ratios of guanine : cytosine and adenine : thymine in single stranded DNA fractions and the fact that DNA from a given source gives a reproducible fractionation profile, indicate that, as with molecular species of transfer RNA, countercurrent distribution of single stranded DNA molecules in this solvent system is at least partly dependent on base sequence as well as net base composition. We have further examined the specificity of fractionation profile by comparing DNAs from several vertebrates. This study was initially designed to obtain information about relatedness among Australian marsupials but clearly it is of more general application.

DNA was isolated by one of three phenol methods[9-11] from liver, spleen or kidney. Contamination by protein[12] was greatly dependent on the source and on the extraction method (Table 1) (compare ref. 13). For countercurrent distribution, DNA was isolated from a given source by the procedure giving consistently low protein contamination. Nucleotide base compositions of DNA preparations were calculated from the melting temperature (*Tm*) in 0·15 M sodium chloride–0·015 M sodium citrate[2] (Table 2) and were found to conform to the generally restricted range observed for other vertebrates[2].

Lizard liver	87·5	44·5
Toad liver	87·3	43·9

Before fractionation, DNA preparations were dialysed against 0·0013 M trilithium citrate, denatured by heating 100° C for 10 min and cooled rapidly on ice (in contrast to earlier studies[5], the strands were not further fragmented). Countercurrent distribution was then carried out in an all-glass automatic apparatus, 3 ml. each phase, in an alkoxyethanol–trilithium citrate system[5], using 4 mg of denatured DNA. The fractionation profile was reproducible with respect to major peaks for different DNA preparations from a given species (Fig. 1). Similar reproducibility was obtained for DNA preparations from different tissues of the same species. This profile is critically dependent on ionic strength[5] and can thus be altered by varying the lithium ion concentration in the solvent system but reproducibility is good in a standard set of conditions.

Comparison of a number of vertebrate species (Fig. 2) demonstrates remarkable differences in countercurrent distribution of single stranded DNA. With the possible exception of fowl and lizard there was little identity of pattern between any two species examined, even in the case of the rodents (Wistar rat, Swiss mouse). Differences among the marsupials (ringtail possum, koala, wombat) were particularly striking.

Studies with bacteria and bacteriophage have produced evidence interpreted variously as favouring the occurrence of specific[15] or non-specific[16] strand breaks during isolation and subsequent handling of DNA. There is as yet little knowledge of the nature or nucleotide base sequence specificity of such DNA breaks in higher organisms. The reproducibility of the fractionation profiles and their apparent species specificity suggest that these breaks are not entirely random, so that countercurrent distribu-

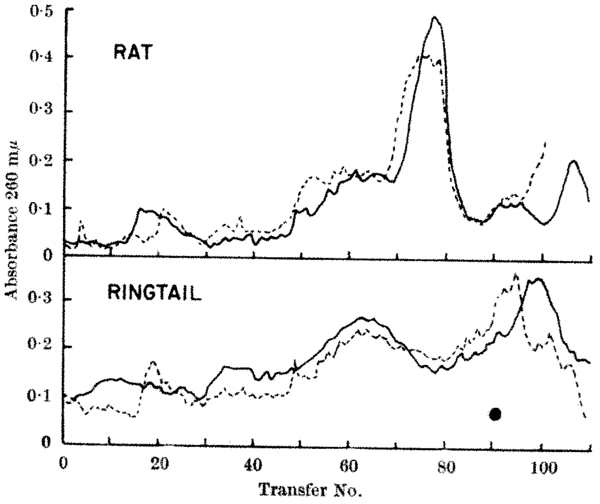

Fig. 1. Reproducibility of countercurrent fractionation profile for single stranded DNA from different individuals of a single species. Countercurrent distribution carried out as in ref. 5; ionic strength, I = 0·028.

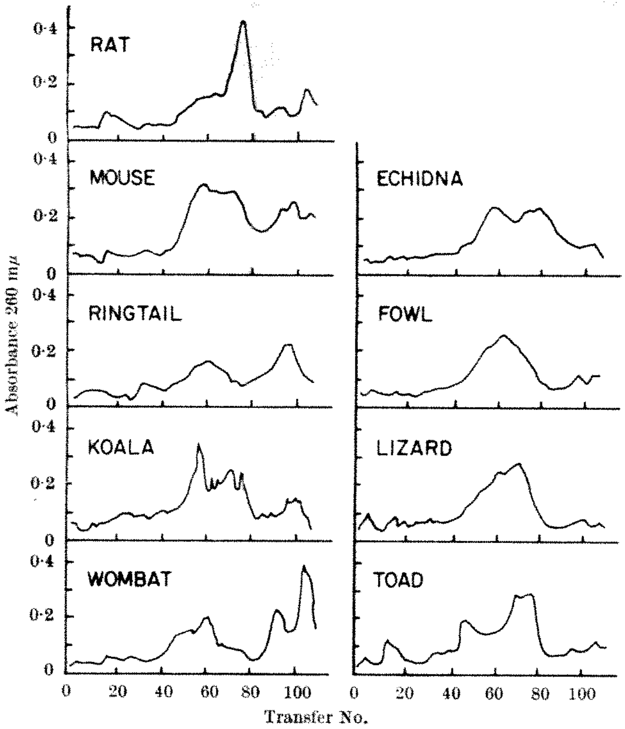

Fig. 2. Species specificity of countercurrent fractionation profile of single stranded DNA. Experimental conditions as for Fig. 1.

tion of single stranded DNA could perhaps serve a useful purpose as a crude fingerprint for a given species. Clearly, by this method alone, it is not possible to ascertain the extent of sequence homologies, but the data do suggest the existence of marked variations in base sequences in DNA of related vertebrate species.

Countercurrent distribution permits the comparison of non-radioactive DNAs, an important practical feature because phylogenetic studies of higher organisms cannot always utilize tissue culture. Countercurrent distribution of radioactively labelled DNA strands may also find useful application in combination with hybridization[4] in the more detailed examination of base sequence homologies.

Morphogenetic Properties of Follicle-stimulating Hormone: Evidence from Effects of Anti-gonadotropin Sera on Developing Chick Embryos

FOLLICLE-STIMULATING hormone (FSH) is able to induce the formation of neural tissue and, in some instances, support differentiation of notochord-like and somitic tissues in chick embryonic systems. Recent experiments have suggested that the primary mesoderm is the target tissue for FSH[1-6]. The latter observation may be of some interest in view of the part played by the mesoderm in the establishment of the embryonic axis. The antigen–antibody reaction is a sensitive and specific reaction. We have attempted, using specific antisera, to obtain some information about the possible importance of FSH or FSH-like glycoproteins in embryonic development.

Antiserum from rabbits against human FSH (anti-FSH-R) and antisera from turkeys against human FSH, HCG and LH (anti-FSH-T, anti-HCG-T and anti-LH-T, respectively) were used. Chick embryos at the definitive primitive-streak stage (stage 4) were explanted *in vitro* according to New's technique[7], and 0·005 ml. of antiserum in 0·2 ml. of Pannett–Compton (PC) saline was added on the embryos which were cultured for 18 h. Controls were maintained using normal rabbit serum or turkey serum obtained before immunization. The results are summarized in Table 1.

Embryos which were cultivated in the presence of normal rabbit serum developed normally (86·4 per cent). About 9 per cent showed general malformation. When treated with anti-FSH-R about 32 per cent of the embryos developed normally while 46 per cent showed malformation of brain and somites often accompanied by degeneration of these tissues (Fig. 1). Development appeared to be arrested at stage 4–5 in 16·3 per cent of the embryos.

Nearly all of the forty-three embryos treated with anti-FSH-T stopped development at stage 4–5. Only about 2 per cent showed malformation. Arrest of development produced by anti-HCG-T was, however, considerably less. But a greater proportion of the embryos treated by the latter produced malformation. Control turkey serum produced very low developmental arrest or mal-

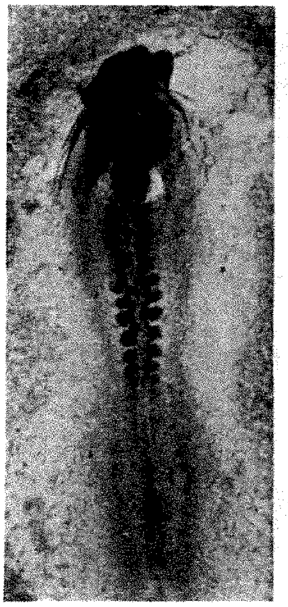

Fig. 1

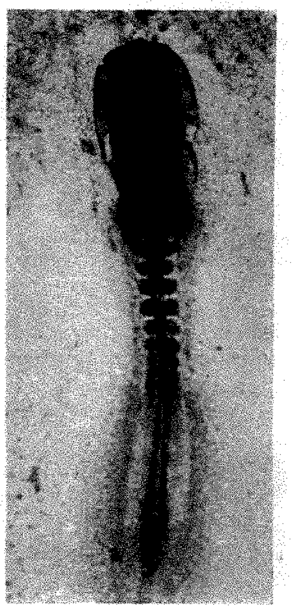

Fig. 2

Fig. 1. Chick embryo treated at stage 4 with anti-FSH-R. Malformation of the brain and degeneration of neural tube and somites to be noted.

Fig. 2. A control chick embryo.

formation. Chicken gamma globulin produced about 7 per cent developmental arrest but a much higher incidence of malformation. It can be reasonably concluded therefore that the developmental arrest was produced by the antibodies themselves and not by indifferent proteins present in the serum.

At a concentration of 0·4 mg (equivalent to 0·005 ml. of antiserum) anti-LH-T produced developmental arrest in 22·4 per cent of treated embryos. When the concentration was doubled arrest occurred in 35·3 per cent and another 53 per cent showed general abnormality. This slight enhancing effect may be due to azide which worked out to a concentration of 0·0008 M. But the lack of any significant rise in developmental arrest with the doubling of anti-LH-T concentration would seem to indicate that arrest produced even at the lower anti-LH concentration may only be a consequence of the presence of small amounts of anti-FSH as an impurity.

The embryos which had undergone developmental arrest were examined histologically. In embryos arrested by anti-FSH-T and anti-HCG-T there was an extensive degeneration of the mesoderm (Fig. 3). In these embryos the epiblast and the hypoblast were apparently not affected by the antisera. Degeneration of the mesoderm in embryos arrested by anti-LH was neither as extensive nor encountered as frequently as in those embryos arrested by anti-FSH-T or anti-HCG.

Differences between the effects produced by the various antigonadotropin sera are obvious. Anti-FSH-R caused predominantly abnormal development but developmental arrest in only a few embryos. Anti-FSH-T and anti-HCG-T, on the other hand, produced chiefly arrested development. Anti-HCG-T also caused malformation to some extent. These differences could be attributed to the fact that the antisera were derived from widely divergent species like rabbits and turkeys. It is to be expected that antisera from turkeys (homologous antibodies) will be more effective than those from rabbits. Anti-HCG-T is able to cross react with FSH (ref. 8). This may explain why the effects of anti-HCG-T are somewhat similar to those of anti-FSH-T. Anti-HCG-T is not as effective as anti-FSH-T in arresting embryonic development.

Gastrulation is a significant event in embryonic development and is accompanied by a sudden rise in the transcription of the genetic information[9]. It is very sensitive to the action of structural analogues of purines and pyrimidines, histones, poly-*l*-lysine and actinomycin[10]. Complete arrest of development at this critical stage by anti-FSH-T and anti-HCG-T sera may indicate the importance of molecules similar to FSH for normal development.

The selective degeneration of mesodermal layer and also cytolysis of the neural tissue and the somites might be caused by immune lysis which is a characteristic feature of the antibody–antigen–complement reaction[11]. The selective effect on the mesodermal layer observed in the arrested embryos seems to confirm our earlier observation that mesoderm is probably the target tissue of FSH. It also suggests a number of other possibilities. It seems plausible that during or subsequent to the invagination of the epiblast through the primitive-streak the cells may be synthesizing or elaborating molecules similar to FSH, or changes might take place in the conformation of glycoprotein molecules present on the cell surface as a result of the processes of invagination. Invagination through the primitive-groove involves a breakdown of the epithelial structure preparatory to differentiation of mesoderm. This process itself might render the mesoderm vulnerable to immune lysis, because organized tissues have not been shown to be as much susceptible to immune lysis as are unorganized or isolated cells[12].

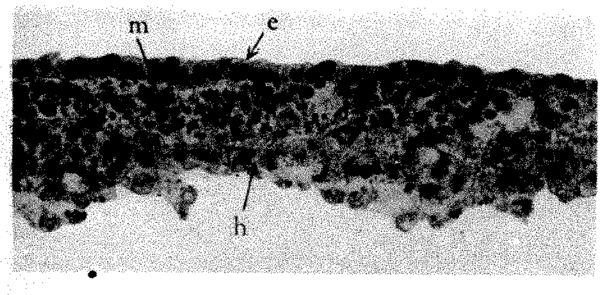

Fig. 3. Section through an embryo arrested by anti-FSH-T showing extensive degeneration of the mesoderm (m). e, Epiblast; h, hypoblast.

Table 1. EFFECTS OF ANTIGONADOTROPIN SERA ON THE DEVELOPMENT OF CHICK EMBRYOS *in vitro*

Treatment	No. of embryos treated	Normal (per cent)	Delayed development (per cent)	Arrest at stage 4–5 (per cent)	Abnormal (per cent)
PC saline	35	79·9	14·3	2·9	2·9
Azide 0·0006 M*	17	76·8	5·8	5·8	11·6
Rabbit serum plus azide 0·00035 M	19	79·2	10·4	5·2	5·2

Effects of Tannic Acid on Erythrocyte Enzymes

MANY properties of the red cell have been studied with the aid of tannic acid since the original observations by Roberts[1]. Treatment with this acid causes reduction in anion permeability[2], agglutination[3], alterations in osmotic resistance[4] and renders erythrocytes capable of adsorbing proteins from solution[5]. The latter characteristic serves as a basis for the widely used procedures of passive haemagglutination. We have shown that the exposure of human erythrocytes to tannic acid, in conditions commonly employed in passive haemagglutination techniques, results in irreversible inactivation of acetylcholinesterase (AChE)[6]. The effect on this membrane enzyme[7] was dependent on concentration, *p*H, time and temperature. Although the mechanism by which tannic acid exerts its action on the red cell has not been elucidated, it has been suggested that in low concentrations this agent traverses the erythrocyte membrane[4]. To test this hypothesis we have investigated the effect of tannic acid on two intracellularly located enzymes, glucose-6-phosphate dehydrogenase (G6PD)[8] and acid phosphatase[7].

Blood obtained from normal adult individuals was centrifuged and the plasma and buffy coat were removed by suction. The erythrocytes were washed thrice with twenty volumes of ice-cold 0·15 M NaCl. A 50 per cent cell suspension was prepared after the last centrifugation and used immediately. A 0·1 per cent stock solution of tannic acid, Fisher Certified Reagent, was prepared in 0·1 M sodium–potassium phosphate buffer adjusted to the required *p*H. Red cells were treated with tannic acid as indicated in Table 1. The activity of AChE was measured at 412 mμ in 0·1 M phosphate buffer, *p*H 8·0, with acetylthiocholine as substrate and 5 : 5′-dithiobis-(2-nitrobenzoic acid) as colour reagent[9]. The activity of G6PD was determined spectrophotometrically at 340 mμ and acid phosphatase was assayed colorimetrically at *p*H 5·0 using 0·1 M acetate buffer and *p*-nitrophenyl phosphate as substrate. Enzyme activity was related to the haemoglobin concentration, which was determined at 540 mμ as cyanmethaemoglobin.

Table 1. EFFECT OF TANNIC ACID ON ERYTHROCYTE ENZYMES

*p*H	G6PD*		Acid phosphatase†		AChE‡	
	Tannic acid	Control	Tannic acid	Control	Tannic acid	Control
6·0	5·9	4·1	0·15	0·15	11	141
6·5	7·5	5·4	0·15	0·14	17	134
7·0	8·0	6·2	0·14	0·15	25	142

Solutions of tannic acid containing 0·1 mg/ml. were prepared in 0·1 M phosphate buffer adjusted to the *p*H indicated. Samples of these solutions (4 ml.) were added to replicate 0·5 ml. samples of a 50 per cent suspension of three times washed red cells. Buffer was added to controls. After 30 min of incubation at 37° C, erythrocytes were washed three times with twenty volumes of chilled 0·15 M NaCl. A 50 per cent suspension was prepared after the last centrifugation. Enzyme activity was determined as indicated in the text.

* Specific activity expressed as μmoles of TPN reduced/min/g of haemoglobin.

† Specific activity expressed as μmoles *p*-nitrophenol liberated in 30 min, at 37° C/mg of haemoglobin.

‡ Specific activity expressed as *ΔO.D.*/min/mg of haemoglobin.

Table 1 shows the results obtained when G6PD and acid phosphatase activity was measured after intact erythrocytes had been incubated for 30 min with 0·1 mg/ml. of tannic acid at 37° C and at three different hydrogen ion concentrations. For comparison the activity of AChE is also given. From these results it is evident that tannic acid had no effect on the activity of the two cytoplasmic enzymes and that only the membrane-located AChE was inactivated by this agent. Similarly, incubation of red cells with tannic acid in a range of concentrations of 0·02 to 0·2 mg/ml., while causing AChE inactivation, did not produce a reduction in the activity of G6PD or acid phosphatase. Exposure to higher concentrations of tannic acid resulted in marked haemolysis. The enzymes of erythrocytes from Negro individuals with genetically determined G6PD deficiency behaved like those from normal subjects.

To make certain that the absence of an inactivating effect on G6PD and acid phosphatase was not a result of a general indifference of these red cells enzymes to tannic acid, the action of this agent on cell-free assay systems was investigated. For this purpose, increasing amounts of the acid were mixed with haemolysates before the addition of substrates and coenzyme. Tannic acid was omitted from the controls. As can be seen in Table 2, both enzymes were inhibited by tannic acid; but whereas 0·02 mg/ml. caused a 72 per cent reduction in G6PD activity, inhibition of acid phosphatase was apparent only at a concentration of 1 mg/ml. The observations are reminiscent of the effects of proteases on erythrocyte enzymes[7]; that is, intracellularly located enzymes are affected in cell-free haemolysates[8], but only AChE activity is destroyed when whole red cells are exposed to small amounts of trypsin, chymotrypsin, papain or bromelin[7]. The finding that cytoplasmic enzymes were not affected when intact erythrocytes were exposed to tannic acid, in conditions which caused irreversible inactivation of AChE[6], does not support the contention that tannic acid is able to traverse the red cell membrane[4], but indicates that this agent only interacts with specific segments of the outer surface of the human erythrocyte membrane[2].

Table 2. EFFECT OF TANNIC ACID ON REACTIONS OF CYTOPLASMIC ENZYMES

Tannic acid (mg/ml.)	G6PD		Acid phosphatase	
	ΔO.D./340 mμ	Percentage activity	*ΔO.D.*/410 mμ	Percentage activity
1·0			0·136	47
0·2			0·260	96
0·1	0·000	0	0·270	98
0·02	0·051	28	0·284	99
0·01	0·113	72	0·298	104
0·002	0·145	92	0·294	102
0·001	0·153	97	0·280	98
None	0·158	100	0·287	100

A stroma-free 1 : 20 aqueous lysate[10] was prepared from a 50 per cent suspension of three times washed erythrocytes. For G6PD, 1·2 ml. of tannic acid was added to replicate cuvettes containing 1·0 ml. of 0·19 M *tris* buffer, *p*H 8·0; 0·1 ml. of 0·3 M $MgCl_2$; 0·1 ml. of 0·02 M glucose-6-phosphate and 0·4 ml. of lysate. Reaction was started immediately by adding 0·2 ml. of 0·002 M TPN and changes in absorbance at 25° C were recorded at 1 min intervals. *ΔO.D.* indicated corresponds to 5 min. For acid phosphatase, 1·0 ml. of tannic acid in 0·1 M acetate buffer, *p*H 5·0, was added to replicate 0·5 ml. of lysate, followed by 1·0 ml. of 0·016 M *p*-nitrophenyl phosphate. After incubation at 37° C for 30 min, the reaction was stopped with 10 per cent trichloroacetic acid and absorbance was determined at 410 mμ in supernatants alkalinized with 0·25 M NaOH.

Chemical Transfer of Learned Fear

RESULTS reported earlier[1–5] have suggested that acquired information can be transmitted to naïve animals by giving them material extracted from the brain of trained subjects. In most of these experiments, as in others[6–11], transfer of information was suggested by varying degrees of statistical probability and it was challenged by negative results obtained in other laboratories[12].

The experiments reported here are easily and rapidly reproducible and yield unequivocal results which clearly demonstrate the possibility of a purely chemical transfer of some types of acquired information. The design of these experiments is based on the well known preference shown by rats and mice for dark rather than lighted enclosures. The preference is reversed if the animals, when they take refuge in the dark, are submitted to a painful stimulus, such as electric shock. This learned fear or passive avoidance, often used for learning studies, was first investigated for the possibility of transfer by Gay and Raphelson[13], who found that naïve recipients injected with extracts of brain taken from trained donors avoided the dark.

In our experiments, donor animals (male Sprague–Dawley rats weighing 200–250 g) were trained in two boxes (the starting box, *S*, made of translucent plastic with a transparent lid, 30 × 20 × 15 cm, and the dark box, *D*, of black plastic on five sides and an electrified grid floor, 25 × 10 × 15 cm) connected by a passage 5 cm long with a cross-section of 8 × 8 cm with a gate. The rat was placed in *S* and, usually, after a few seconds ran into *D*. The gate was then closed and the animal received electric shocks (2 mA) for 5 s through the grid floor. When the gate was lifted, the animals ran back into the starting box or were returned to it. The operation was repeated five times: each shock period of 5 s was separated by an interval of 10 to 15 s. One such session was given to the donors daily for 6 or 8 days, unless otherwise stated.

Between 1 and 2 h after the last training session the rats were decapitated, their brains were rapidly removed, frozen in dry ice and stored at − 20° C until use. Brains from groups of animals similarly trained were pooled, weighed and homogenized with water in a glass tube with a motor driven 'Teflon' pestle. In the first experiment, the homogenate was stirred for 5–6 h in an ice bath, kept in the refrigerator for 14–16 h and centrifuged at 80,000*g* for 1 h. The volume of the supernatant was adjusted so that 1 ml. was equivalent to 2 g of brain. In the most recent experiments, the homogenate was poured into 'Cellophane' bags and dialysed against 20 volumes of distilled water for 20–24 h. The dialysate was lyophilized and the residue was redissolved in distilled water. Other extraction procedures will be described later together with the chemical properties of the transfer factor. The extracts were kept frozen at − 20° C until use.

The recipients were male Swiss mice weighing 20–25 g. The same boxes were used as for the training of donors, but a third compartment was attached to the starting box. This white box (*W*), made of the same material as *S*, was connected to it by a passage identical with the one linking *S* to *D*.

Before injection, mice were screened so as to eliminate those that did not show a definite dark preference; animals that did not spend in the dark at least 90 out of a total of 180 s were eliminated. In 348 mice, the mean time in the dark box was 138 ± 19 (*S.D.*) s.

After screening, the mice were injected intraperitoneally with the brain extracts and tested at varying intervals. Testing, like screening, consisted of placing the animal in *S* with both gates open. By means of stop watches or, in more recent experiments, with a photoelectric system, the time spent in all three compartments was recorded for 180 s. The observers had no knowledge of the treatment received by the animals. The results are shown in Table 1 in terms of the mean number of seconds spent in *D* (TDB) 1, 2 and 3 days after injection.

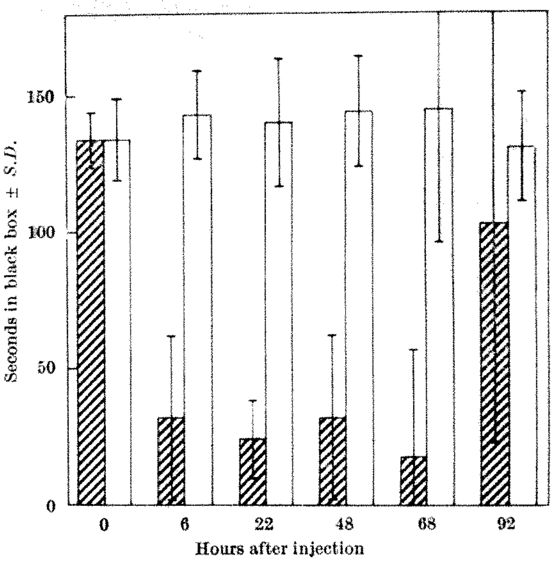

Fig. 1. Action of brain extracts on dark-light preference in naïve mice. Abscissa, interval between injection of extracts and test; ordinate, time spent in dark box out of a total of 180 s. White columns, mice injected with untrained brain (12); hatched columns, mice given extract of brain from rats which had acquired fear of dark (18). Vertical lines indicate standard deviations.

In the first experiment, thirty mice were divided into two groups: eighteen of group 1 mice received the supernatant of the homogenate of brain taken from donors trained for 8 days—amounts equivalent to 1 g of rat brain were injected into each mouse; in group 2, twelve mice were injected with the same dose of similarly prepared extract of untrained rat brain. The results, shown in Fig. 1, indicate that the extract from untrained animals had no significant effect on the behaviour of the recipients, but the trained extract considerably shortened TDB. The significance between the means, computed by the *t* test, indicates $P < 0{\cdot}001$ until the fourth day when most of the animals reverted to the preinjection pattern of behaviour.

Table 1. INFLUENCE OF DONOR TRAINING AND DOSE OF BRAIN INJECTED ON AVOIDANCE IN RECIPIENTS

Training of donors (days)	Amount of brain injected (g)	TDB (s) ± *S.D.* recipients		Units/g ± *S.D.*	
2	1·0	74	23	1·66	0·50
	1·5	26	14		
4	0·3	98	27	2·73	0·67
	0·6	67	25		
	1·0	24	28		
6	0·4	72	29	3·38	0·56
	0·6	63	22		
	0·8	27·5	9		
8	0·3	86	15	3·46	0·30
	0·6	56	17		
	0·9	16	6		
11	1·0	54	22	2·01	0·62
15	1·0	82	25	1·22	0·71
8 (+5)*	1·0	33	17	2·60	0·45
8 (+10)*	1·0	76	22	1·37	0·64

All donors were subjected to five periods of 5 s shock (total 25 s) daily. Groups of six mice were used.

* Numbers between parentheses indicate number of days between last training day and removal of the brain.

In the next series of experiments, the effect of varying amounts of brain was studied. As shown in Table 1, the effect increased with the dose of brain material injected. Another significant factor was the length of training given to the donors and Table 1 shows that the transfer effect increased with the length of training up to 8 days. For longer periods of training, the effect declined sharply. The decline was less marked with donors trained for 8 days and given 5 or 10 days rest before removal of the brain.

Given the quantitative relationship between dose and effect, it was possible to establish a unit of activity defined as the amount of material reducing TDB to 90 s. The content of the brain in transfer factor could be expressed in these units (last column of Table 1).

In all these experiments, the donors were given five periods of 5 s of shock every day. In other experiments, varying amounts of shock were given daily. It is seen in Table 2 that one 5 s period per day for 6 days (total of 30 s) did not give satisfactory results. When shock was given for 50 s daily, the results resembled those of 11 days training with 25 s/day. It therefore seemed likely that the total exposure to shock may bear some relation

Table 2. EFFECT OF TOTAL DURATION OF SHOCK GIVEN TO THE DONORS AND THE INTERVAL BETWEEN TRAINING AND BRAIN REMOVAL ON AVOIDANCE IN RECIPIENTS

Days in training	Total duration* of shock (s)	Interval between last session and brain removal (h)	TDB (s) ± *S.D.*		Units/g ± *S.D.*	
6	30	2	91	31	0·97	0·89
6	300	2	51·5	29	2·08	0·53
1	150	0·1	135	19	0	
1	150	2	107	38	0·52	0·34
1	150	6	66	31	1·68	0·88

1	150	18	51	38	2·10	1·07
1	150	24	43·5	34	2·31	0·96
1	150	36	70	41	1·56	1·15
1	150	48	85	43	1·14	1·21

Groups of six mice were used.

* Given in periods of 5 s separated by intervals of 10 to 15 s.

Table 3. CHEMICAL PROPERTIES OF THE TRANSFER FACTOR

Extract	TDB	± *S.D.*
Supernatant	27	15
Dialysate	30·5	28
Retentate	136·5	12
Phenol phase	40	20
Aqueous phase	143	13
Trypsin treated	134	23
Chymotrypsin treated	32·5	25
Ribonuclease treated	26	21
Incubated control*	23	16

In all experiments groups of six mice were used. The injected amount was 1 g/mouse.

* Incubated without enzyme at *p*H 8 and room temperature for 1 h to serve as control to the trypsin treated sample.

to the amount of transfer factor present in the brain. Experiments were set up to see whether massing thirty periods of 5 s in 1 day would give results similar to five periods of training for 6 days. In these experiments, however (Table 2), the result depended also on the interval between the last trial and the removal of the brain. It seems that although the training and the electric shocks trigger the formation of the transfer factor, it requires several hours for the synthesis of sufficient amounts of this factor. In these experiments, the best results were obtained after 12 to 24 h. The decreasing effect of extracts obtained after longer intervals suggests a rapid destruction of the transfer factor.

The chemical properties of the transfer factor have been investigated. Table 3 shows that the substance responsible for the factor is dialysable. When the dialysate was submitted to phenol partition the activity was found in the phenol phase. When the dialysate was incubated for 1 h with trypsin, chymotrypsin or pancreatic ribonuclease at the optimum *p*H of these enzymes, trypsin destroyed the activity while the other enzymes had no effect. The transfer factor has been purified by precipitation with acetone, passage on 'Sephadex *G*-25', 'Dowex 50' and 'Dowex 1'. At the present state of purity, one unit of activity corresponds to approximately 5 μg of partially purified extract.

The experiments just described have shown that fear of the dark, acquired by training, can be transferred to naïve animals by material extracted from the brain of trained donors. The degree of transfer depends on at least three factors: the amount of brain administered, the length of training of the donors and the interval between training and removal of the brain. The transfer factor is probably a basic peptide with between six and ten amino-acid residues. According to the hypothesis proposed by one of us to explain the molecular storage of acquired information[14], peptides of this size would have adequate information content to secure the new neural connexions required for most types of learned behaviour.

Simplified Procedure for Immunodiffusion Techniques on Cellulose Acetate

METHODS using cellulose acetate membrane (CAM)* for immunodiffusion were introduced 8 yr ago[1,2], but were slow in gaining recognition, possibly because the immunodiffusion had to be carried out under oil to prevent evaporation from the thin, microporous membrane. Diffusion in simple moist chambers is not entirely reliable except perhaps when gelatinized CAM ('Cellogel') is used[3]. A simple device is described here which ensures constant saturation of the CAM during diffusion by resting this on an electrolyte solution soaked filter paper support.

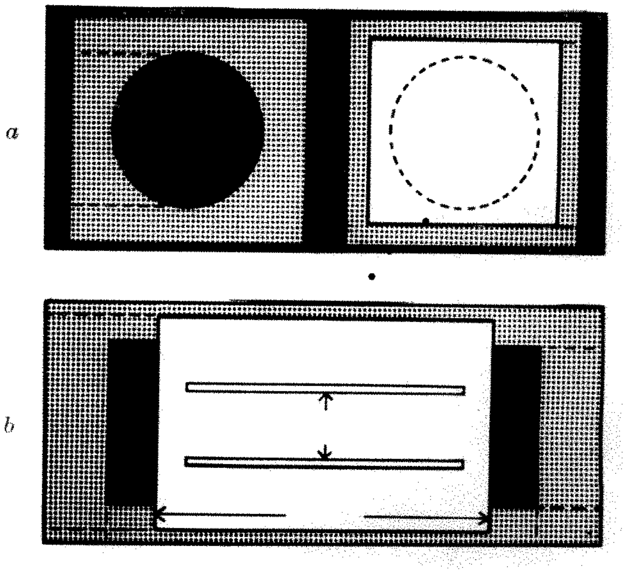

Fig. 1. *a*, Filter paper support cut out and prepared for bidimensional immunodiffusion. Dimensions: 5 mm thick, 5·5 × 5·5 cm with 3 cm diameter hole cut out. One CAM square with samples applied in position on pad. *b*, Filter paper support for immunoelectrophoresis with CAM strip placed in position. Dimensions: 5 mm thick, 5·5 × 12 cm with 3·5 × 10 cm rectangle cut out (for strips 7–10 × 5 cm). Antiserum strips applied to the CAM.

For bidimensional immunodiffusion, round holes (about 3 cm in diameter) are cut out from square filter paper pads, 4–6 mm thick (for example, a few layers of Whatman No. 3 MM), Fig. 1*a*. This forms a support which is placed on filter paper in a suitable flat container (about 2–3 cm high) with a well fitting lid and soaked with an appropriate electrolyte solution—the excess fluid being drained off; it should not be too wet. The CAM cut either in squares or disks, for example, 4 × 4 cm and of 4 cm in diameter, is marked with the required application pattern in indelible ink or pencil. It is then impregnated with electrolyte solution, blotted and placed on the pad in such a way that the diffusion area spans the gap and the periphery is in contact with the support, overlapping it by about 5–10 mm. The samples containing antigen and antibody are applied to the surface of the CAM as discrete drops by means of a micropipette or capillary, taking care to avoid "blow out" bubbles. The distance between the application sites will vary, usually it is about 5–10 mm; 0·5–2 μl. would be the usual volume for the peripheral applications and about twice as much for the central one. After the samples have been applied the lid can be closed. The diffusion time depends on the nature and concentration of the antigen and antibody, the distance of application sites and the temperature. With 1 cm distance, diffusion for 16–24 h at room temperature is usually adequate. After diffusion the CAM is removed and placed in an eluting fluid, such as 0·2 per cent 'Haemo-Sol' (Meinecke and Co., Inc., USA; Alfred Cox (Surgical),

---

* All brands appear to be suitable for the purpose; Sartorius CAM was used in this study.

Ltd., UK) buffer or saline for about 10–20 min, preferably with agitation. After elution the CAM is stained, washed, dried and cleared as recommended for CAM electrophoresis. For weak precipitates 0·002 per cent Nigrosin in 2 per cent acetic acid is a most useful stain.

For immunoelectrophoresis, electrophoretic separation is carried out following the procedure recommended for CAM. For the most commonly used semi-micro technique, strips about 7–10 cm long, 3–5 cm wide and a bridge gap of 6–8 cm are used. One or two samples (about 0·5–2 μl.), applied as a drop or short streak, can be run, depending on the width. Bromophenol blue, added to the serum sample, will mark the size and shape and monitor the exact position of the albumin fraction, which should travel within about 15 mm from the bridge end. Good results have also been obtained with a separation pattern only 3 cm long. After electrophoretic separation the CAM strip is removed and placed on an impregnated rectangular filter paper support in a suitable container (Fig. 1*b*) in such a manner that only the sides of the strip are in contact with the support, overlapping it by about 5 mm. The size and shape of the support depend on the particular requirements; for example, for serum immunoelectrophoresis, 6 × 12 cm with a cut out central rectangle about 4 × 8 cm (Fig. 1*b*). Filter paper strips (about 1–2 mm wide) impregnated with antiserum are now applied to the electrophoretic strip in the desired pattern and distance, parallel to the separated fractions, about 3–4 mm as measured from the margin of the coloured albumin spot. The antiserum strips should be somewhat longer than the separation pattern and should not be applied closer than 5–6 mm from the edge of the support. Usually more antiserum will have to be added to the strip in position (carefully with a micropipette), for the ratio of serum to antiserum should be about 1 : 20–40 depending on the titre, the optimal ratio being established for each system. After the correct volume of antiserum has been applied, the container can be closed. Alternatively a ruling pen or a thin brush, guided along the edge of a ruler, proved to be quite a convenient and for some perhaps an easier way of applying the antiserum. Diffusion time for serum immunoelectrophoresis is usually 16–24 h; the optimal time is determined by experience. After diffusion, the strip is lifted from the support and the antiserum strips are washed off under the tap. The rest of the procedure is as described here for the bidimensional technique. Examples of patterns obtained are shown in Fig. 2*a* and *b*.

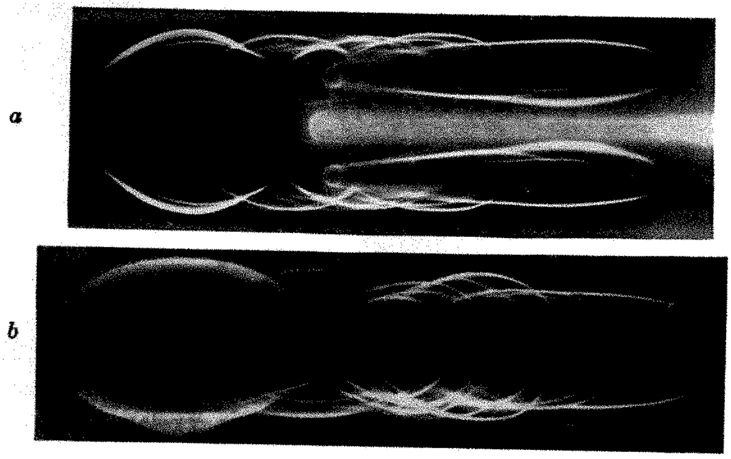

Fig. 2. *a*, Immunoelectrophoretic pattern. Stained with Ponceau S, uncleared strip, direct enlargement, negative print. Two samples of serum applied, lateral antiserum strips—anti human serum, central antiserum strip—anti immunoglobulin serum. Run for 1 h, 24 h diffusion period. *b*, Immunoelectrophoretic pattern. Ponceau S-stained uncleared strip, direct enlargement. Human serum against anti human serum, run for 1 h, 24 h diffusion period.

The most common errors of the techniques described here are: untidy application of samples; faulty electrophoretic technique; fingerprints; letting the CAM dry out at any stage before staining; imperfect adherence of CAM to support (if necessary a thin piece of impregnated filter paper, similar in shape and size to the support, placed on top of the CAM will ensure perfect contact); over saturated support pad; incorrect application and insufficient volume of antiserum; overcrowding, antigen and antiserum too close.

MICROBIOLOGY

Preservation of Coccidial Sporozoites by Freezing

Maintenance of cultures of coccidia for experimental purposes is laborious and expensive. To overcome these difficulties, we attempted to freeze and store sporozoites of *Eimeria meleagrimitis* Tyzzer, 1929, and *E. tenella* (Railliet and Lucet, 1891) Fantham, 1909, in liquid nitrogen vapour. Sporozoites, liberated in the usual manner[1], were suspended in media containing 7 per cent dimethyl sulphoxide and frozen to −80° C at the controlled rate of 1°/min; they were then stored in a cylindrical tank about 3 in. above liquid nitrogen.

After being stored for 1 month, sporozoites of each species were quickly thawed in water at 43° C and inoculated into cell cultures (bovine embryonic kidney; cell line, twentieth passage) and into the caeca or duodenum of chicks and turkey poults, respectively. Control cultures and birds were inoculated with unfrozen sporozoites. In cell culture, both species developed to mature schizonts in a manner previously described[2–4]. There seemed to be no significant difference between frozen and non-frozen sporozoites in their patterns of development. Frozen sporozoites inoculated into birds produced oocysts and lesions similar to those produced in birds inoculated with freshly excysted sporozoites.

Sporocysts containing sporozoites, released from oocysts by grinding[1], were also frozen. Oocysts were produced when the sporocysts were thawed and fed to birds. The intensity of the infection, however, was less than in birds fed freshly released sporocysts.

We have an abundant stock of frozen sporozoites and sporocysts of both species and intend to compare them with freshly released sporocysts or excysted sporozoites at regular intervals. Preservation of coccidia by freezing will make the maintenance of stock cultures less time consuming and make it possible to work with "parent strains" for an extended time.

Isolation of *Vibrio parahaemolyticus* from the Northwest Pacific

In Japan, *Vibrio parahaemolyticus* has been reported to be the major cause of gastroenteritis associated with the consumption of sea foods[1]. *V. parahaemolyticus* has been shown to occur in large numbers in coastal waters and marine sediments around Japan in summer months, but not in the winter[2]. This seasonal pattern is also apparent in food poisoning outbreaks due to *V. parahaemolyticus*[3].

The first reported isolation of *V. parahaemolyticus*-like organisms in the United States was from Puget Sound and Washington Coast sediments[4]. Approximately 10 per cent of the vibrios isolated from these sources showed characteristics similar to those described for *V. parahaemolyticus*. In this communication, work confirming the occurrence of *V. parahaemolyticus* in seawater, sediments and shellfish in the Puget Sound region and a procedure for the isolation and identification of this organism are reported.

Significant reductions in counts were obtained when Japanese strains of *V. parahaemolyticus* were quantitatively plated on media described by the Japanese workers[1,2,5,6] for the isolation of the organism from water, sediment and sea food materials. A satisfactory, semi-selective, solid medium was formulated on the basis of the invariant ability of *V. parahaemolyticus* to utilize starch. The components were: 0·3 per cent Bacto peptone; 0·1 per cent Bacto yeast extract; 0·5 per cent soluble potato starch; 1·5 per cent agar; 5 per cent sodium chloride; and distilled water to 100 per cent, adjusted to *p*H 7·5. Surface-inoculated plates of the medium were incubated in an anaerobic jar at 37° C for 36–48 h. Interfering organisms other than *Bacillus* types were suppressed and halophilic vibrios grew readily and could be recovered quantitatively. Where samples were known to contain large numbers of *Bacillus* types, such as marine sediments, the incorporation of 2 U/ml. of penicillin in the medium was found to be effective in greatly reducing contamination. Non-spreading, smooth, translucent colonies that showed starch hydrolysis were sub-cultured on human blood agar. Isolates that haemolysed blood at 37° C were considered presumptive positive. These isolates were then confirmed by testing in accordance with the method of Shewen[7] for Gram-negative bacteria and of Sakazaki[6] for halophilic vibrios. The testing procedure of Sakazaki is a scheme for the differentiation of *V. parahaemolyticus* from *V. alginolyticus* and *V. anguillarum* (Table 1). Sakazaki[6] reported that *V. alginolyticus* and *V. anguillarum* are the most commonly encountered vibrios from marine sources. The differentiation is based principally on the salt tolerance of these vibrios.

Table 1. DIFFERENTIATION OF *V. parahaemolyticus* FROM *V. alginolyticus* AND *V. anguillarum*

Characteristics	*Vibrio parahaemolyticus*	*Vibrio alginolyticus*	*Vibrio anguillarum*
Growth in 1% trypticase broth			
With 3% NaCl	+	+	+
With 7% NaCl	+	+	−
With 10% NaCl	−	+	−
Voges–Proskauer reaction	−	+	−
Sucrose fermentation	−	+	+ or −
Cellobiose fermentation within 24 h	−	−	+
Colony morphology on starch agar	Smooth	Swarming	Smooth

The differentiation scheme is based on Sakazaki data[6].

V. parahaemolyticus was found in relatively large numbers during the summer from all Puget Sound water, sediment and oyster samples. Numbers of this vibrio ranged from 30 to 350/ml. in the water samples, from 100 to 2,000/g in the sediment samples, and from 65 to 4,000/g in the oyster samples. In samples collected during the early spring and early fall, however, the counts of *V. parahaemolyticus* were very low; this situation paralleled that described by Japanese investigators[2]. Two hundred isolates from all the samples tested were studied extensively by standard taxonomic procedures. Simultaneously, 40 strains of *V. parahaemolyticus* obtained from Japan were tested. The more important characteristics of these organisms are shown in Table 2. Except for their ability to ferment sucrose, the Puget Sound isolates were physiologically identical. Sakazaki[1,6] reported that *V. parahaemolyticus* does not ferment sucrose; nevertheless, seven of the forty strains obtained from Japan fermented this sugar. The slow fermentation of cellobiose by *V. parahaemolyticus*, a differentiating property used by the Japanese investigators[6], was not found to be a useful taxonomic criterion. The forty Japanese strains tested showed various degrees of cellobiose fermentation, ranging from slow to very rapid. The same variability existed among the Puget Sound strains. On the basis of these data, it is concluded that the isolates from Puget Sound were physiologically indistinguishable from the Japanese strains. It is also apparent that the related biotypes *V. alginolyticus* and *V. anguillarum* (Table 1) were not encountered in the samples taken from Puget Sound.

Table 2. BIOCHEMICAL CHARACTERISTICS OF JAPANESE AND PUGET SOUND ISOLATES OF *V. parahaemolyticus*

	Organisms tested	
Reaction	Japanese strains *V. parahaemolyticus** (40)† Total positives	Puget Sound isolates (200) Total positives
(1) Growth in 1% trypticase broth		
With 0% NaCl	0	0
With 3% NaCl	40	200
With 7% NaCl	40	200
With 10% NaCl	0	3
(2) Glucose (acid)	40	200
(3) Lactose (acid)	0	0

(15) Penicillin sensitivity (2·5 U)	0	0
(16) Single-polar flagella	40	200
(17) Gram stain (negative)	40	200

All media, unless designated, were made up with sea water or 3 per cent NaCl. All biochemical tests were run at 37° C.

* Cultures received from Japan.

† Number in parentheses indicates the number of cultures tested.

Serological identification of *V. parahaemolyticus* is not reliable[6], and so we tried to isolate bacteriophages specific for *V. parahaemolyticus* by enrichment of water, sediment and homogenized oyster preparations with the organism. It was hoped that such a procedure would provide definitive identification of the organism. Enrichment of thirty-five samples yielded two bacteriophages specific for *V. parahaemolyticus*, both from Pacific oyster homogenates. The two phages showed specificity to ten of forty Japanese strains and one Puget Sound strain of *V. parahaemolyticus*. The related biotypes, *V. alginolyticus* and *V. anguillarum*, were not lysed by these phages. It is expected that many of the Puget Sound strains are lysogenic, for there has been evidence of cross lysis between different strains. The isolation of specific bacteriophages supports the evidence that *V. parahaemolyticus* is not an exclusive inhabitant of Japanese waters and may be ubiquitous in coastal areas throughout the world. Furthermore, the association of specific vibrio phages with the Pacific oyster strongly implicates this animal as a potential carrier of *V. parahaemolyticus*.

The isolation of *V. parahaemolyticus* from inshore waters and its apparent association with oysters is of considerable significance, particularly in view of the outbreaks of food poisoning in Japan caused by this organism. The fact that many of the cases of food poisoning in the United States and other countries were due to agents of unknown aetiology[8] should justify the inclusion of specific tests for the detection of *V. parahaemolyticus* from suspected sources.

This research was supported in part by the US Office of Naval Research and the US Public Health Service.

Japanese strains of *V. parahaemolyticus* were given by R. R. Colwell, and *V. alginolyticus*, *V. anguillarum*, and additional strains of *V. parahaemolyticus* were given by R. Sakazaki.

Identification of Rhinovirus Strain *D.C.*

In 1953, Andrewes et al.[1] reported the propagation of a virus in cultures of primary human embryonic lung from nasal washings of a patient (D. C.) with a common cold. Although no cytopathic effects were noted, culture fluids from the fourth to the tenth passage produced colds in volunteers whereas control fluids did not. At that time, attempts to repeat these experiments were unsuccessful. Using nasal washings from individuals inoculated with D. C. material, Tyrrell *et al.*[2] attempted to propagate the *D.C.* virus in primary human embryo kidney cultures in conditions favourable for recovery of rhinoviruses. Although these tests were also unsuccessful, these workers were able to propagate a virus, with production of cytopathic effects, in human diploid fibroblast cultures. This development led to the recognition of the agent as a rhinovirus. It is probable but not certain that this virus is the same as that which was in the original D. C. nasal washings.

Recently, a collaborative effort by several laboratories led to the internationally accepted numbering system for rhinoviruses. The initial report[3] by this group described a numbering system for fifty-five distinct (rhinovirus) serotypes and one subtype. Although *D.C.* virus was not included in this programme, it was of sufficient historical interest to warrant an attempt to identify it with antisera prepared against the fifty-six numbered rhinoviruses. Serum neutralization tests were carried out with *D.C.* virus and fifty-six rhinovirus antisera. Antiserum for rhinovirus type 9 (strain 211) neutralized *D.C.* virus. No reactions occurred with the remaining antisera. Subsequently, a complete cross neutralization test was performed with *D.C.* and type 9 viruses and antisera. Similar tests were made in the Salisbury laboratory using different antisera prepared against these viruses. The results of the tests are shown in Table 1. It is clear that *D.C.* virus is a strain of rhinovirus type 9 for which the prototype virus is strain 211, first described in 1961 (ref. 4).

At the time, the early experiments could only be interpreted as meaning that a virus which caused the common cold had been grown in cell culture. It is now evident that the virus was a typical rhinovirus, a member of the group of organisms found most commonly in this type of illness.

Primary Exo-erythrocytic Forms of *Plasmodium vinckei*

The first strain of *Plasmodium vinckei* Rodhain, 1952, was isolated by Vincke from *Anopheles dureni* caught by the River Kinga near Albertville (Katanga—Democratic Republic of the Congo). Unfortunately, at that time only the erythrocytic forms were described : cyclical transmission was not achieved in the laboratory.

P. chabaudi was found in 1965 by Landau[3] near Bangui (Central African Republic). The blood forms seemed to be very similar to *P. vinckei*.

In 1967, the isolation of a new strain of *P. vinckei* from *A. dureni* was reported[1]. The first observations on mosquito transmission[1] soon showed that the sporogony of this plasmodium is not as easy to perform as that of *P. berghei*. It not only requires a suitable temperature and humidity, an adapted invertebrate host, and a vertebrate host which would be not only susceptible to sporozoites but would also be a producer of gametocytes able to infect mosquitoes. In spite of the presence of gametocytes in laboratory white mice, only low infection rates were recorded in mosquitoes fed on these animals; only splenectomized mice were able to infect about 50 per cent of the mosquitoes. Hairless mice, however, produced a large number of viable gametocytes resulting in good infections in *A. stephensi* without splenectomy.

Out of five species of *Anopheles* (*A. stephensi*, *A. quadrimaculatus*, *A. gambiae*, *A. albimanus*, *A. atroparvus*) and *Aedes aegypti* only the first showed oocyst development and sporozoites in their salivary glands after an infective blood meal. In *A. quadrimaculatus* a high percentage of infections was obtained in the midgut. The oocysts grew normally to maturity and gave a great number of sporozoites, but not a single parasite could be found in the salivary glands.

Sporozoites were found in the salivary glands of *A. stephensi* after 14 days incubation at 20° C and after 11 days at 25° C. The size of mature oocysts varied between 40 and 70μ. The mean length of the sporozoites, measured *in vivo*, was 15μ (ranges 11–20μ). Incubation temperatures of 16° C and 27° C have been successfully used for the sporogony of *P. vinckei*.

Liver biopsies and autopsies were performed on seven mice and four rats (*Thamnomys surdaster*) inoculated with sporozoites of *P. vinckei* so as to find the exo-erythrocytic schizonts. The shortest maturation time of the tissue schizonts was determined by subinoculation of blood from these animals. The livers were fixed in Carnoy's fluid for 3 h, and the biopsies for 2 h. Sections (4μ) were stained by the Giemsa-colophonium method[2].

In one experiment, mosquitoes (*A. stephensi*) were fed on two hairless mice, on the fifth and sixth days after the mice had received an intraperitoneal inoculation of blood from a strain kept for 125 days in dry ice. The mosquitoes were incubated at 21° C. The infection rate of the salivary glands was 60 per cent. Two suspensions of sporozoites (from twenty-five and thirty-one mosquitoes) were prepared by a method used for standard inoculations of sporozoites of *P. berghei*[3] and were injected intravenously into two mice. The sporozoite count in a haemocytometer (Neubauer) showed fifty-six and seventy sporozoites/mm^3 (21,000 and 28,000 sporozoites were injected, respectively).

In another experiment, a young *Thamnomys surdaster*, probably the natural host of *P. vinckei* in Katanga, was inoculated with 45,000 sporozoites (0·9 ml. of a suspension of fifty sporozoites/mm^3). This suspension was made by crushing twenty-one mosquitoes infected after feeding on two hairless mice.

Sub-inoculation of blood from this *Thamnomys* after a single inoculation of sporozoites showed that the primary exo-erythrocytic schizonts of *P. vinckei* mature in 53 h. Schizonts were present in biopsies and autopsies of seven mice and four *Thamnomys* after single intravenous inoculation of sporozoites from various batches of mosquitoes.

At 48 h (mouse) the schizonts were immature, round, oval or irregular in shape and surrounded by a thin membrane. The nuclei are obscured by blue cytoplasmic aggregations. The mean measurement was about 24μ (19–27μ) (Fig. 1).

At 53 h (*Thamnomys*) mature and even ruptured schizonts were found. About twenty schizonts were found in each section. The mean measurements of the largest schizonts (twenty-one in number) were 33–42μ (range, 21–50μ) (Fig. 2).

At 54 h (mouse), 55 h (two mice and a tree rat), and 56 h (one mouse) most schizonts became mature. The nuclei are small, very numerous and regularly distributed and each is surrounded by a small blue cytoplasmic area. Some schizonts show rosette patterns or nuclei arranged in zones separated by areas of light blue cytoplasma. Other forms, although mature, have heavy blue cytoplasmic aggregations. Mean measurements were 23–30μ (range, 18–34μ). The schizonts found in the liver of tree rats are larger than those found in mice; mean measurements were 29–42μ (range, 23–51μ). Scanty mature forms were found in livers taken after 60–61 h from two mice and a rat.

It must be emphasized that many similarities can be found between *P. vinckei*, Rodhain, and *P. chabaudi* described by Landau and Killick-Kendrick[4] and studied by Wery[5]. For both these parasites healthy sporogony is possible at 21° C, 25° C and 27° C; sporozoites can be found in the salivary glands after 14 days at 21° C, and after 11 days at 25° C. Fully mature oocysts show a wide range of sizes from 40 to 70μ; the pigment of the oocysts is heavy and arranged rather in clumps than in lines.

The mean length of the sporozoites is 15μ. The earliest mature primary exo-erythrocytic schizonts are found at 52–53 h in *P. chabaudi* and at 53 h in *P. vinckei*. The nuclei are small and numerous, sometimes arranged in rosettes. Some schizonts have a sponge-like aspect, and blue cytoplasmic aggregations. The mean size at 53–54 h is about 30 × 40μ with a very wide range up to 51μ. It should also be remembered that both parasites are hardly distinguishable in the erythrocytic stages. Moreover, white rats and hamsters are refractory to both parasites. The course of infection in mice is more benign than *P. b. berghei*. Cross immunity between *P. chabaudi* and *P. vinckei* has been reported[6–8].

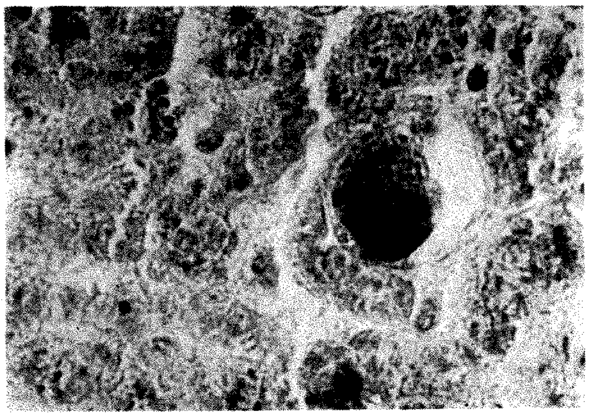

Fig. 1. Photomicrograph of section of liver (mouse) after 48 h showing immature exo-erythrocytic schizont of *P. vinckei*. Note basophilic aggregations of cytoplasma.

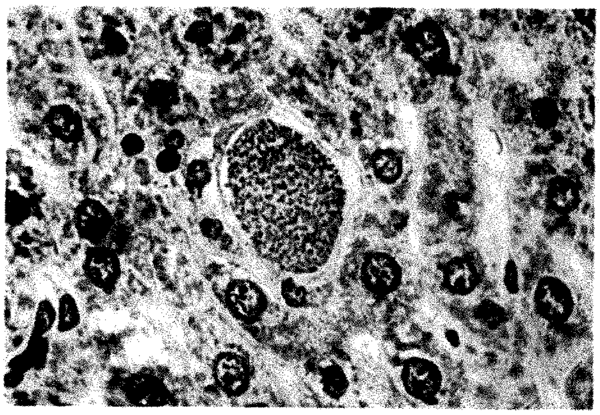

Fig. 2. Photomicrograph of section after 53 h of liver (*Thamnomys*) showing mature exo-erythrocytic schizont of *P. vinckei*.

It seems that *P. chabaudi* is morphologically and serologically very similar to *P. vinckei*, so *P. chabaudi* Landau, 1965, should be considered as a subspecies of *P. vinckei* Rhodhain, 1952. The taxonomic status of this species becomes *P. vinckei chabaudi* (Landau, 1965, nov. taxon).

I thank Professor I. H. Vincke and Professor P. G. Janssens for their help and encouragement.

Corrosion of Iron and Formation of Iron Phosphide by *Desulfovibrio desulfuricans*

THE classical theory of anaerobic bacterial corrosion, postulated by von Wolzogen Kühr and van der Vlugt[1], states that certain organisms, primarily those of the bacterial genus *Desulfovibrio*, remove hydrogen (electrons) that accumulate on the surface of iron (cathodic depolarization) by means of a hydrogenase, and reduce SO$_4^{--}$ to S^{--}. As a result of electron removal, iron dissolves as Fe^{++} ions at the anode.

It was recently demonstrated that a strain of *Desulfovibrio desulfuricans* would cathodically depolarize mild steel in a nitrogen atmosphere if the electron acceptor was the redox dye benzyl viologen (BV) (ref. 2). When a 1010 steel coupon was placed on a (2 per cent) agar (containing BV and *tris* buffer [*tris*(hydroxymethyl)aminomethane], *p*H 7·0 ± 0·1) surface so that half of the coupon (cathode) rested on a mass of cells (*D. desulfuricans*, mid-continent strain *A*), the BV was reduced by the cells. The iron dissolved as Fe^{++} ions at the half of the coupon (anode) that was not in contact with the cells. In summary, the reaction at the anode is: $Fe \rightarrow Fe^{++} + 2e$ and at the cathode

$$2e + 2H^+ \rightarrow 2H \rightarrow H_2 + 2BV \rightarrow 2BV_e + 2H^+$$

If a coupon was placed on 2 per cent yeast extract (YE) agar (*p*H 7·0 ± 0·1) plus BV (0·01 per cent) with cells of the same strain under one-half of the coupon, the results seemed to be the same. A depolarization current of 2 μA/cm² was obtained by the technique reported earlier[2]. When the experiment was repeated without BV in the YE agar, blackening occurred in the agar under the half of the coupon in contact with the cells. The black area became blue-green when developed with aqueous potassium ferricyanide solution (10 per cent w/v), indicating the presence of Fe^{++} ions. No Fe^{++} ions were found in the agar under the half of the coupon not in contact with the cells (Fig. 1). The black area, which extended several mm into the agar, seemed to consist of particles < 1μ in diameter. Black particles were also found in the cells. On treating the cells with the potassium ferricyanide solution, blue-green areas were found in the cells indicating local concentrations of Fe^{++}.

When $MgSO_4 \cdot 7H_2O$ (0·2 per cent) was substituted in place of BV as an electron acceptor in YE agar, the results seemed to be the same as with YE agar alone. The cells and agar under the coupon again became black. The substitution of $MgSO_4 \cdot 7H_2O$ (0·01 per cent) for BV in *tris* buffer agar produced no cathodic depolarization effect; that is, no increase in iron concentration at the anode as compared with a control system (no cells). In both of these systems, no sustained cathodic depolarization current was obtained, and the polarity of the system was unstable in that polarity continually reversed. These results seemed to indicate that the cells were reducing some material other than sulphate in the YE agar and a "short circuit" was occurring in the system (both anodic and cathodic reactions were occurring at the same area of the steel coupon that was in contact with the cells).

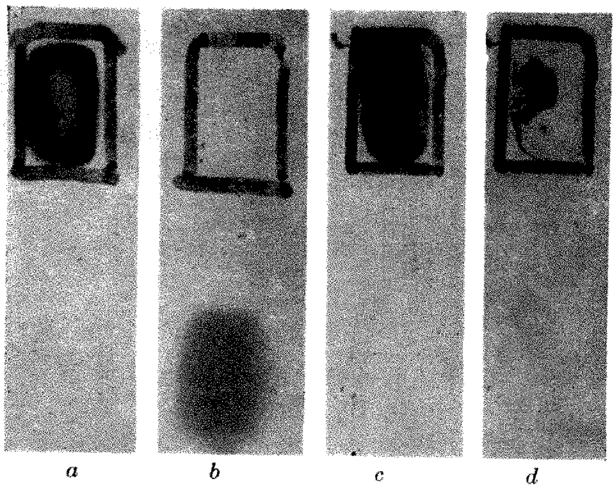

Fig. 1. Areas in agar under coupon indicating location of iron and reduced benzyl viologen (BV). *a*, Yeast extract (YE) agar plus BV surface immediately after removal of steel coupon. Dark area (cathode) caused by reduction of BV by *Desulfovibrio* cells. *b*, Same plate, 15 min after addition of aqueous potassium ferricyanide (10 per cent w/v) indicating a concentration of Fe^{++} ions at the anode (no cells). *c*, YE agar minus BV immediately after removal of steel coupon showing dark area under cells. *d*, Same plate 15 min after addition of aqueous potassium ferricyanide showing concentration of Fe^{++} ions.

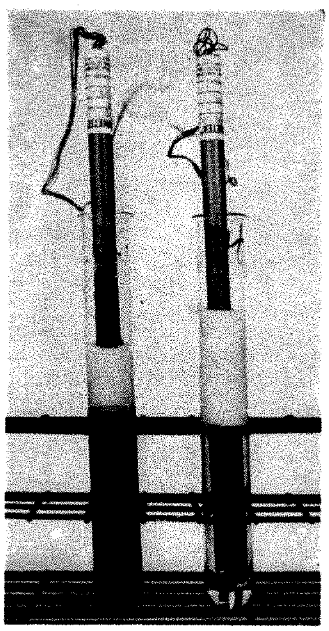

Fig. 2. Two corrosion probes (1010 steel) in yeast extract (2 per cent) (*p*H 7·0 ± 1) sealed with vaspar (equal portions of vaseline and paraffin). Tube at left, inoculated with culture of *Desulfovibrio desulfuricans* (mid-continent *A* strain). Tube at right, uninoculated control. After 2 days incubation at 26° ± 1° C.

Sterile YE broth (2 per cent) *p*H 7·0 ± 0·1, containing a steel coupon, when inoculated with a pure culture and incubated in a hydrogen atmosphere, often became black within 24h, depending on the effectiveness of oxygen removal. A clump of cells on the surface of the steel coupon often became black within 1 h or less. In a nitrogen atmosphere, the time for blackening was often delayed by a day or two. The same results were observed with three other cultures of *Desulfovibrio*, one of which was isolated from a tubercle in a water pipe, and a species of *Clostridium* isolated from tap water. The surface of the steel coupon usually remained just as bright as when it was placed in the YE broth; that is, except for where it came in direct contact with the black sediment at the bottom of the tube.

An attempt was made to measure this corrosion in tubes of inoculated YE (2 per cent) broth (10 ml./tube) using a corrosion probe (model *S*001, *S*4) of 1010 steel (Magna Corporation, Santa Fe Springs, California) with a Corrosometer (model *CK*, Crest Instrument Co., Santa Fe Springs)[3]. After several weeks' incubation at 26° ± 1° C, no detectable difference in resistance in the probe specimen could be seen between three probes in inoculated YE broth (0·14 mg SO_4^{--}, precipitated as the barium salt/ml.) and three probes in sterile YE broth. One of the inoculated tubes with probe and a sterile control are shown in Fig. 2. Because the corrosion rate was less than 2·6 mg/dm²/day (limit of sensitivity of metre for a 3-day interval), it may have been equal to or less than the corrosion rate established for the cathodic depolarization of 1010 steel using BV as the electron acceptor (2·5 mg/dm²/day[1]). Corrosion of probes could not be detected within 4 weeks in inoculated YE plus $MgSO_4 \cdot 7H_2O$ (0·2 per cent), and YE plus sodium lactate (4 ml./l.) and $MgSO_4 \cdot 7H_2O$ (0·2 per cent).

It was suspected from some observations made during the isolation of *Desulfovibrio* from tubercles in a water main that the blackening of the YE broth might be produced by a cell-free enzyme liberated in the medium. Seitz filtrates (cell-free) of 3-day-old YE broth cultures of the four strains of *Desulfovibrio* and the *Clostridium* sp.

containing a steel coupon were subsequently found, using the Thunberg technique, to reduce methyl viologen (Eo = −411 mV), and benzyl viologen (Eo = −315 mV) in a hydrogen atmosphere. No reduction was observed in a nitrogen atmosphere. A sterile 1010 steel coupon in the Seitz filtrate of these strains in a hydrogen atmosphere produced blackening of the filtrate, usually within 24 h, if oxygen removal was nearly completed. In the same system under a nitrogen atmosphere, a flocculent black precipitate was first formed on the surface of the metal. Complete blackening of the filtrate was delayed for about 24–48 h compared with the time of blackening in a hydrogen atmosphere. It seemed that the small amounts of hydrogen on the steel surface were evidently initially limiting the reaction.

A sterile Seitz filtrate of 3 day old blackened YE broth culture of the mid-continent strain in contact with 1010 steel coupons under H_2 was again allowed to react with sterile 1010 coupons. After 3 days under an H_2 atmosphere a black precipitate was obtained. X-ray diffraction analysis of this non-magnetic material (dried in vacuum) was negative for elemental iron or any compound of iron. When the black material was heated to 2,250° F in vacuum for 15 min and slowly allowed to cool to room temperature for about 20 h, it was magnetic. X-ray diffraction analysis of this material indicated that it was iron phosphide (Fe_2P). Mössbauer studies indicated that the material before heating was also iron phosphide, but colloidal in nature.

Further investigation of this reaction is in progress. It is suspected that phosphate in the yeast extract is reduced in the presence of hydrogen by the hydrogenase of *Desulfovibrio* to phosphine, which then reacts with the ferrous ions to produce iron phosphide[4,5]. If this assumption is validated, it would also indicate that the phosphate may be selectively reduced in preference to the sulphate, in the presence of iron, because both compounds are present in the yeast extract.

Because the black precipitate of iron phosphide seems to be similar to the black precipitate of iron sulphide, and because blackening of the media in which sulphate reducers are growing is usually assumed to be iron sulphide, further analysis of this material would seem warranted.

I thank C. J. Bechtoldt and Dr J. J. Spijkerman, US National Bureau of Standards, for the X-ray diffraction analysis and Mössbauer studies, respectively.

IMMUNOLOGY

Synthesis of some Serum Proteins in Lymphocytes stimulated by Phytohaemagglutinin

SMALL lymphocytes are stimulated by phytohaemagglutinin (PHA) to increase the synthesis of RNA and DNA and to undergo transformation into blast-like cells. It has been shown by immunofluorescent and electrophoretic techniques, as well as by incorporation of amino-acids labelled with carbon-14, that stimulation with PHA results in the production of globulins[1-5], some 10 per cent or more of which can be precipitated by specific anti-γ-globulin[5]. In an investigation using radioimmunoelectrophoresis, Sell *et al.*[3] found no immunoglobulins, but did find α and β-globulins which were not clearly identified. The problem of *in vitro* synthesis of immunoglobulins in several lymphocytes is therefore still a matter of controversy.

We investigated the incorporation of lysine labelled with carbon-14 into the proteins of lymphocytes of healthy individuals stimulated with PHA and in patients with IgG and IgA plasmacytomas.

Lymphocyte suspensions of volume 2 ml. ($4–5 \times 10^6$ lymphocytes) were prepared in the usual way[6] using 8 ml. of medium 199 (Difco) with and without PHA. Twenty-four hours after the preparation of the cultures, lysine labelled with carbon-14 (Radiochemical Centre, Amersham; specific activity 41·0 μCi/mg) was added in a concentration of 0·5 μCi/10 ml. of culture. Lymphocytes of normal individuals were collected according to the method of Rabinowitz[7,8] and examined in the same conditions.

After 3 days, the cells were centrifuged and washed twice with Hanks solution. The cell sediments of several cultures were then combined, frozen and thawed four times. After centrifugation at 35,000g the precipitate—which consisted mostly of broken cells—was discarded and the supernatant diluted 1 : 1 with autologous serum as a carrier medium. Ouchterlony double diffusion tests and immunoelectrophoresis were performed in duplicate.

In the autoradiographic experiments, 'Currix' X-ray film (Gevaert, clear base) and *G*150 developer (Gevaert) were used. Autoradiography was carried out simultaneously on the immunoelectrophoreses of PHA-stimulated and non-stimulated lymphocyte preparations. The films were exposed for 1, 2, 4 and 6 months. The following antisera were used: two different polyvalent horse anti-human sera (Institute Pasteur, Paris), two different rabbit anti-human sera (Behring-Werke AG, Marburg), specific antisera against IgG, IgA, IgM, K-Bence-Jones, L-Bence-Jones, F(ab), F(c), β_{1a}, β_{1c}, α1-lipoprotein, α1-antitrypsin, α1-orosomucoid, and Gc-globulin (this antiserum was not strictly monospecific, but precipitated two other α-globulins besides Gc-globulin).

Proteins labelled with carbon-14 could be detected in all cultures to which PHA had been added. Their mobility toward the anode was similar to the α1, α2 and β-globulins of serum. The concentration of the proteins which moved towards the cathode was lower; usually two fairly well defined zones could be seen (Fig. 1). The findings in the lymphocyte lysates of both normal individuals and myeloma patients were identical. There was no increase in paraprotein concentration. In the non-stimulated lymphocytes no proteins directed towards the anode could be detected after exposure for 1–2 months, but traces of such proteins were, however, found after exposure for 6 months (Fig. 1*b*).

Using polyvalent anti-human antiserum two precipitates differing in concentration were recognized in the α1-globulin region: one precipitate in the α2-globulin region and a short weak precipitate in the γG-globulin region (Figs. 1*a*, 2). Using specific antisera the precipitate located in the α2-globulin region was identified as α2-macroglobulin.

The strong line of precipitate in the α1-globulin region corresponded with a protein precipitable by anti-Gc-globulin serum. Because this antiserum was not strictly monospecific against Gc-globulin, it remains to be seen whether this precipitate is indeed Gc-globulin (Hirschfeld's "group specific component"). After exposing the immunoelectrophoresis for 6 months this protein could also be shown in the non-stimulated cell lysates.

Furthermore, after stimulation with PHA and exposure of the films for 4–6 months an IgG-like precipitate could be detected. It was always very weak in concentration and therefore present only in a short zone within the IgG-precipitate of the carrier serum, located close to the well towards the cathode.

These findings suggest that three to five proteins are synthesized in lymphocytes stimulated by PHA. On the basis of immunoelectrophoretic criteria and Ouchterlony techniques it was shown that these proteins are identical with serum proteins. An adsorption of material labelled with carbon-14 by the precipitates of the carrier serum seems unlikely, because the ability to bind such material has been attributed to lipoproteins and albumin but not to the proteins described here. Although protein synthesis in non-stimulated lymphocytes is significantly lower, an α1-globulin (perhaps Gc-globulin) can also be demonstrated. In comparison with the results of Sell *et al.*[3] it was noted that their α-globulin-precipitate was probably identical with the protein we have identified as Gc-globulin (?). In their experiments, a relatively short exposure time was chosen which could explain why other serum proteins and IgG could not be identified. The concentration of IgG—which was not increased in myeloma—was extraordinarily low and was certainly not too high as was suggested by others[1,5]. On the basis of the sensitivity of the antisera and the extraordinarily long exposure time the concentration of IgG can be estimated to be about 1/100 to 1/1,000 of the total protein synthesis after PHA stimulation.

Induction of Immunological Paralysis to Heterologous Tumours

TRANSPLANTATION studies have proved that the relative ease of tolerance induction in newborn animals is inversely proportional to the strength of the antigens to which tolerance is to be induced—that is to the strength of immunity they can induce in adults[1]. The rate and pattern of heterograft rejection, as well as the difficulty of inducing acquired tolerance to heterografts, has demonstrated the high strength of the interspecific histocompatibility barrier[2,3].

The failure of xenogeneic lymphoid cells to induce tolerance to heterografts when administered to the newborn may reveal some peculiarity of the host immunological apparatus, such as (*a*) a precocious maturation of the reactivity to heterologous antigens during ontogenesis[4,5], or (*b*) a genetically predetermined ability of a large part of the immunological system to react against some "obligatory" strong antigens[6,7].

A large part of the cell population reacting against xenogeneic antigens can be conceived not only on the grounds of an *a priori* immunological potency, but also as a consequence of a cumulative mechanism of action of the different non-self determinants present in the antigenic complex[1,8,9]. The more genetically dissimilar the antigen donor and recipient the larger are the doses of antigen needed[7]. Induction of heterograft tolerance would presumably depend on the administration of very large doses of donor antigens to inhibit the reactive population of immunocompetent cells.

It seems, however, that the most important condition for tolerance is the persistence of antigen[10]. If this is so, lack of the tolerogenic effect of the xenogeneic lymphoid cells might be the consequence, not of a violent host reaction but of an inability of the xenogeneic lymphoid cells to multiply[11] and thus cause persistence of antigens in the presence of an excess of the host's very strong antigens. Theoretically, fulfilment of this requirement for tolerance demands that antigen sould be repeatedly introduced. This principle is well illustrated by immunological paralysis to defined antigens, when, more often than not, unresponsiveness which is not actively maintained by continuous administration of the antigen, is eventually replaced by immunity[12].

To investigate which of these critical factors is essential to the induction of heterospecific tolerance, we have attempted to define the conditions of time and dosage required for the induction of tolerance to mouse tumours by administering xenogeneic spleen cells to rats. This communication is concerned with the onset and duration of unresponsiveness and with the kinetics of tolerance, as determined with tumour grafts. Tolerance was considered to be complete when actively growing tumours resulted after challenge. Animals which appeared tolerant at first but developed immunity later (rejecting the tumours) were considered to be partially tolerant.

For the paralysis treatment, spleen cells from *CBA* mice prepared by the method of Billingham[13], were inoculated intraperitoneally into newborn inbred Lewis rats, which were between 24 and 48 h old when the treatment began. The same amount of spleen cells (that is 250 to 450 × 10^6) per recipient was administered, either in single doses or in fractionated doses, given as five or ten injections at daily intervals.

The rats were challenged when 30 days old, by intramuscular inoculation of trypsinized cell suspensions containing 30 × 10^6 viable tumour cells. All except one group were challenged with tumour cells derived from a mammary carcinoma (*Ca/CBA*) that had appeared spontaneously in a *CBA* mouse. This tumour was in transplant generation 1–3 (performed by subcutaneous grafting of tumour fragments in *CBA* mice) when it was used in these experiments. In order to verify previous observations the non-specificity of heterologous tolerance to the isoantigens of the donors[14], we tested one group of rats with a sarcoma induced by methylcholanthrene in a *C57Bl/ScSn* mouse (*MC/Bl*$_1$ sarcoma).

Table 1. INDUCTION OF TOLERANCE IN NEWBORN RATS TREATED WITH MICE SPLEEN CELLS

Induction of tolerance		Challenge (30 day old rats)		No. of rats which developed tumours/No. of rats tested	No. of rats with developing tumours/No. of rats with regressing tumours
Injection period (days of life)	Total *CBA* spleen cell dose/rat	Days from treatment until challenge	Tumours (30 × 10^6 cells) used for challenge		
1	250	29	*Ca/CBA*	0/10	
1	350	29	*Ca/CBA*	0/10	
1	450	29	*Ca/CBA*	0/12	
1–5	250	25	*Ca/CBA*	0/8	
1–5	350	25	*Ca/CBA*	0/10	
1–5	450	25	*Ca/CBA*	0/12	
2–6	250	24	*Ca/CBA*	0/12	
2–6	350	24	*Ca/CBA*	0/8	
2–6	450	24	*Ca/CBA*	0/10	
1–10	250	20	*Ca/CBA*	7/12	2/5
1–10	350	20	*Ca/CBA*	10/12	4/6
1–10	450	20	*Ca/CBA*	16/16	16/0
2–11	250	19	*Ca/CBA*	5/10	0/5
2–11	350	19	*Ca/CBA*	8/10	2/6
2–11	450	19	*Ca/CBA*	10/12	8/2
1–10	450	20	*MC/Bl*$_1$	20/20	20/0

The results in Table 1 show that tolerance to the *Ca/CBA* tumour was not induced in rats by one or five injections of *CBA* spleen cells, irrespective of the dose used. In groups receiving ten injections of spleen cells, beginning in the first 24 or 48 h of life, tumours appeared after challenge, and their incidence seems to be directly related to the total number of spleen cells inoculated. The degree of tolerance also seems to depend on the dose of spleen cells inoculated. In groups treated with 450 × 10^6 cells, most animals developed lethal tumours when tested with *Ca/CBA* tumours and *MC/Bl*$_1$ sarcomas, and died at between 7 and 8 weeks of age; tumours also appeared in groups treated with smaller doses, but were rejected after 2 weeks in most rats.

Recovery from paralysis seems to be caused by the production of new immunocompetent cells by escape from suppression of previously tolerant cells, depleted of an internal store of antigen[15,16]. We conclude that in partially tolerant animals the conditions of tolerance and immunity may potentially coexist, the degree and duration of unresponsiveness being dependent on the ratio[14,17] of the number of blocked cells to the number of sensitized cells. On the assumption that one state can be converted into the other, depending on the concentration of antigen per cell and/or per population, we tried to reinduce tolerance by further supply of spleen cells in animals which had rejected the heterologous tumours.

Rats given, during the first 10 days of life, a total of 250–350 × 10^6 *CBA* spleen cells in ten injections, were challenged at 30 days with 30 × 10^6 *Ca/CBA* tumour cells. Animals which rejected the tumours were reinoculated between the fortieth and fiftieth days of life with 115–125 × 10^7 spleen cells given in ten injections. A control group of normal rats was treated at the same age with 150 × 10^7 *CBA* spleen cells. When 60 days old, they were inoculated intraperitoneally with 30 × 10^6 *Ca/CBA* tumour cells. Table 2 shows that although the total dose of spleen cells was the same for all groups (that is 150 × 10^7 cells), tolerance resulted only in rats treated during the neo-natal period. The incidence and degree of tolerance again seemed to be related to the dose administered within this period. This result suggests that the probability of success in tolerance reinduction depends on the degree of the host's unresponsiveness when the antigen is reintroduced.

Table 2. REINDUCTION OF HETEROGRAFT TOLERANCE IN POST-TOLERANT RATS

No. of *CBA* spleen cells (× 10^6) inoculated		Total spleen cell dose per rat (× 10^6)	No. of *Ca/CBA* tumour cells (× 10^6) inoculated: days of age:		Results obtained after challenge of 60 day old rats	
1–10 days of age	40–50 days of age		30	60	No. of rats which developed tumours/No. of rats tested	No. of rats with developing tumours/No. of rats with regressing tumours
250	1,250	1,500	30	30	6/18	3/3
350	1,150	1,500	30	30	10/17	7/3
—	1,500	1,500	—	30	0/20	—

We investigated mouse lymphoid cell chimaerism in tolerant rats. Chromosome patterns were studied in the thymus, femoral bone marrow and spleen of rats bearing tumours of lethal size. Neither rats challenged at 30 days nor those challenged at 60 days showed mouse metaphases in their lymphoid organs. These animals showed no symptoms of runt disease.

Histological examination (using haematoxylin and eosin) of tumours developed in heterologous hosts, revealed no modification of the original mouse tumour. *Ca/CBA* tumours invaded the rat thigh muscle and the peritoneal cavity (Figs. 1–2). If fragments of these tumours were back transplanted in *CBA* mice, typical *Ca/CBA* tumours developed. The mouse tumours growing in rats were not transplantable to untreated adult Lewis rats.

The fact that tolerance to heterologous tumours was inducible in 48 h old rats invalidates the assumption[4,5] that the host's immunological immaturity at the time of treatment with antigen is a necessary and short-lived condition for the induction of tolerance. On the other hand, the alternative hypothesis that tolerance is exclusively related to the establishment of an optimum relationship between the amount of antigen and the number of immunocompetent cells[15] does not fully account for our finding that whereas xenogeneic cells given in a single injection are inefficient, the same quantity of cells administered repeatedly is likely to induce tolerance. These results and earlier ones[14,17,18] show that the most important element in heterologous tolerance induction is the administration of antigen over a prolonged period. Heterologous spleen cells seem unable to achieve lymphoid chimaerism, and so it might seem that repeated inoculations are necessary to maintain the critical concentration of antigen. But because tolerance was reversed even after the onset of immunological rejection, it may be that heterospecific tolerance can be achieved gradually through the action of antigen in blocking the sensitized and hypersensitized cells if these are exposed continuously to large concentrations of antigen. The experiment now described was an attempt to determine whether paralysis can be induced in immunologically mature animals where a high

Table 3. INDUCTION OF HETEROGRAFT TOLERANCE IN IMMUNOLOGICALLY MATURE RATS

Tumour cells injected	Paralysis treatment Route of inoculation	Age (in days) of rats when injected	Results No. of rats which developed lethal tumours/No. of rats treated
385×10^6 *MC/Bl*$_1$ sarcoma cells/rat	Intraperitoneal + intramuscular alternately	17–87	10/10
385×10^6 *MC/Bl*$_1$ sarcoma cells/rat	Intraperitoneal + intramuscular alternately	27–97	10/10

degree of immunity is the rule[19], by injection of such strong antigens as heterologous cells.

The paralysis treatment consisted of a long course of tumour cell injections. The mouse sarcoma *MC/Bl*$_1$ in transplant generations 1–6, was used throughout this experiment. The tumour was maintained in the *C57Bl/ScSn* strain by intramuscular transfer of 5×10^6 cells at 2–3 week intervals. Two groups of Lewis rats were treated simultaneously (Table 3): the first received 385×10^6 viable *MC/Bl*$_1$ cells for 10 weeks, starting at 17 days of age; the second group received the same treatment, starting at 27 days of age. Injections were given daily, alternately intraperitoneal and intramuscular, during the first month; every other day during the second month, and once a week during the last 2 weeks. Tumours became palpable approximately 10 days after the last injection. In the next 18–20 days, all animals developed large tumours which had invaded the peritoneal cavity and lungs (Figs. 3–5). Transplantation of rat tumours back into *C57Bl/ScSn* mice confirmed their similarity to the original mouse tumours. These experiments seem to confirm our hypothesis that a process of gradual paralysis may be involved in the induction of heterospecific tolerance.

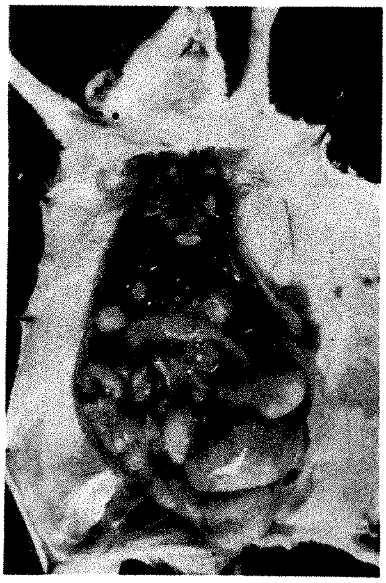

Fig. 1. An 85 day old rat, in which tolerance was reinduced by spleen cell treatment. The organs of its peritoneal cavity are invaded by a *Ca/CBA* tumour heterotransplant. Inoculation of tumour cells given on the 60th day of life.

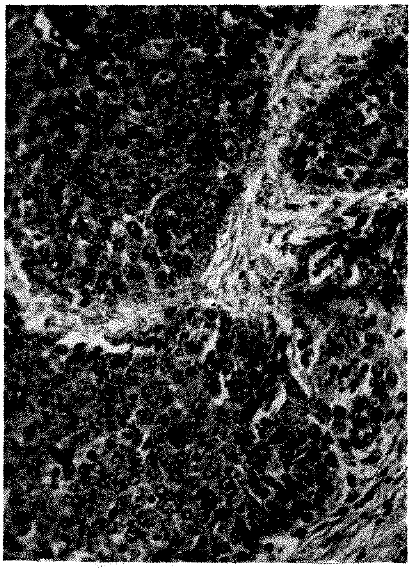

Fig. 2. *Ca/CBA* tumour growing in rat. (Haematoxylin and eosin. × c. 70.)

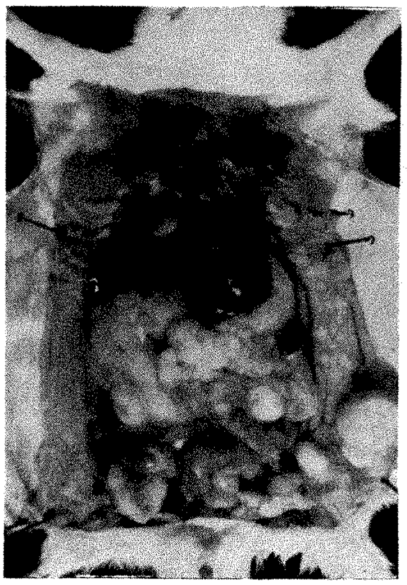

Fig. 3. Intraperitoneal invasion of the *MC/Bl*$_1$ mouse sarcoma in a 127 day old rat, treated with tumour cells between the twenty-seventh and ninety-seventh day of life.

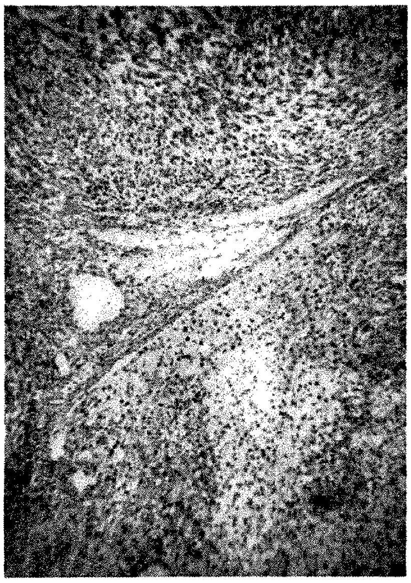

Fig. 4. *MC/Bl*$_1$ sarcoma growing in a 3 month old rat, showing tumour invasion of the liver. (Haematoxylin and eosin. × c. 70.)

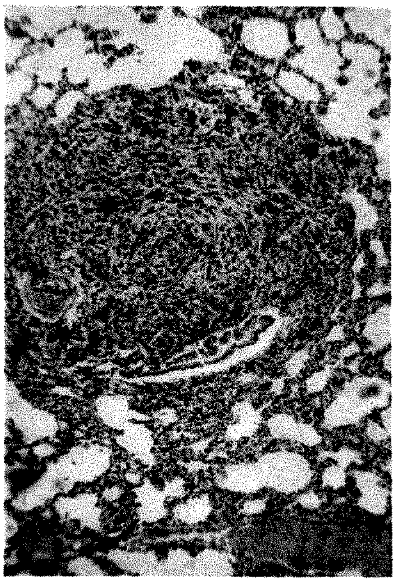

Fig. 5. The heterotransplanted MC/Bl_1 sarcoma invading the lung of a 3 month old rat.

Our findings show that: (*a*) immunological tolerance to heterografts can be induced through long-term paralysing treatment, not only in newborn animals but in adults as well; (*b*) tolerance can be maintained or reinduced by an adequate supply of antigen at the time when recovery from paralysis occurs; and (*c*) xenogeneic spleen cells have a tolerogenic effect without producing a graft versus host reaction.

Heterograft tolerance is specific to the donor's species but displays no specificity to the donor's isoantigen so it might be possible to supply antigens and transplants from heterogeneous donor populations.

I thank Professor Theodor Burghele for his generous support and encouragement, and Miss Elena Cristea and Miss Ana Bartok for their expert technical assistance.

PATHOLOGY

Mites in Bedroom Air

VOORHORST *et al.*[1] found that, among the many constituents of house dust causing allergic reactions of the respiratory tract (rhinitis and asthma) in people sensitive to house dust, a hitherto little known Pyroglyphid mite, *Dermatophagoides pteronyssinus*, contains allergens that are much more potent than those of other constituents. They also showed that excretory or secretory products of the mite contain the allergens. It therefore seemed probable that the mite could cause severe inhalation reactions should it become temporarily airborne and reach the upper or lower respiratory tract. Mechanical disturbance during bedmaking seemed a possible launching mechanism for making the mites airborne, especially because one of us (A. M. C.) found that *D. pteronyssinus* is very abundant in mattress dust.

To test this hypothesis a cyclone dust extractor, of diameter 15 cm, powered by centrifugal fans (giving an intake velocity of 300 cm/s in tests 1–4 (Table 1), and 1,900 cm/s in tests 5–7) was operated 2 ft. above the floor to collect dust from the air during bedmaking. In tests 1–4 the apparatus would extract particles efficiently down to the equivalent of 10μ spheres from 0·4 m^3 of air per min, and in tests 5–7 its efficiency should have been increased to retain 3μ spheres from 3·0 m^3 of air per min. The cyclone was operated during bedmaking (including turning the mattress) and after for 5 to 15 min each day. Samples were accumulated for several days in each test. The samples consisted of a loose pellet of fibrous material and a fine deposit on the wall of the receptacle consisting mainly of material from the stratum corneum.

Table 1. NUMBERS OF *Dermatophagoides pteronyssinus* CAUGHT IN CYCLONE DUST EXTRACTOR DURING BEDMAKING IN 1967

Sample	Collection date	Dust (mg/m^3 of air)	Mites/m^3 of air sampled	Mites/g of airborne dust

* Estimated.

† After regular vacuum cleaning of mattress.

The samples were weighed, dispersed in 90 per cent lactic acid, held in this at 55° C for 24–48 h, and the suspension was examined for mites. These were removed, mounted for microscopic examination, identified and counted.

As well as *D. pteronyssinus*, a few representatives of other species were present. These included a second Pyroglyphid species, *Euroglyphus maynei*, the Acarid species *Acarus siro* and *Tyrophagus putrescentiae*, and the Glycyphagid mite *Glycyphagus domesticus*.

Clearly *D. pteronyssinus* can become airborne during bedmaking, and its numbers decreased with attempts to remove mattress dust (Table 1); it was not present in hospital air. Others have shown that mites can be inhaled[3-5]. Whole mites or considerable portions in the dust can be identified to species level microscopically, but this cannot yet be done with the finest debris of fragmented mites, which with their faecal pellets also occur in the airborne dust, and which may constitute a more serious source of allergens than the mites themselves.

We thank Professor A. C. Cunliffe for arranging the aerobiological sampling in hospital wards.

Absorption of *d*-Glucose by the Rabbit Jejunum during Cholera Toxin-induced Diarrhoea

CHOLERA exotoxin causes fluid production by the intestine when instilled into jejunal or ileal loops of anaesthetized rabbits[1-3]. Profuse quantities of isotonic fluid are produced by the small intestine without histological alteration of the mucosa[4]. The pathogenesis of the increased fluid production by the intestine in cholera is unsettled. It has not been determined whether the fluid production is the result of increased intestinal secretion, decreased intestinal absorption or a combination of these two factors. To assess the importance of altered intestinal absorption, absorption of *d*-glucose by the rabbit jejunum was measured both in the presence and absence of cholera diarrhoea.

Ten white male New Zealand rabbits weighing 2–3 kg were studied after an 18 h fast. The animals were anaesthetized with 10 mg/kg of sodium pentobarbital given intravenously. Hydration was maintained with intravenous Ringer lactate infused at a rate of 60 ml./h for the duration of the experiment (4 h). The abdomen was opened and a loop of jejunum approximately 15 cm long (7–10 vascular arcades) just distal to the ligament of Treitz was isolated. Both ends of this loop were transected between vascular arcades to preserve the blood supply[5]. The cut ends of the intestine were ligatured to prevent spillage.

The proximal end of the loop was cannulated with flanged polyethylene tubing (*PE* 200), while the distal end was cannulated with latex rubber tubing (internal diameter 3/16 in.). A similarly constructed loop was made in the adjacent jejunum thus creating two jejunal loops in each rabbit. The isolated loops were carefully washed with 40 ml. of Ringer lactate, emptied and then returned to the abdominal cavity. The abdomen was then closed, leaving only the catheters exposed. Rectal temperatures were monitored and the body temperature was maintained between 102° and 104° F with the aid of a heat lamp.

In one group of five rabbits (cholera group) 10 ml. of cholera toxin[6] prepared by Dr John Feeley (Lot No. *H*062867) was placed in both loops and allowed to remain there for 4 h. In five other control rabbits (control group) 10 ml. of Ringer lactate solution was instilled into both loops for 4 h, after which the loops were drained and emptied by flushing with air. Then, using an autoanalyser pump the loops of the control and the toxin treated animals were continuously perfused with a solution containing 26 mM *d*-glucose and 0·3 mM phenol red (PSP) in Ringer lactate. The PSP was employed as a non-absorbable marker. A sample of the test solution (50 ml.) was continuously perfused and the efflux from the loop was recirculated from a reservoir through the loop at a rate of 2 ml./min[7].

Before beginning the experiment, duplicate 1 ml. samples were obtained from the reservoir for determination of the initial concentration of glucose and PSP. The perfusion was begun and 1 ml. samples were collected from the reservoir at hourly intervals. The glucose concentration was determined on each sample using the method of Hoffman[8] modified for the 'Autoanalyser' (Technicon Instrument Corp., New York). PSP was determined colorimetrically by the method of Schedl *et al.*[9]. The final volume contained in the reservoir and the loop was obtained by dividing the amount of PSP placed in the system (corrected for PSP removed during the experimental period) by the final PSP concentration. The glucose absorbed was calculated by subtracting from the amount placed in the reservoir the amount in each sample and the amount remaining at the end.

After 4 h of perfusion the animal was killed and reopened. The loops were examined to ensure that the blood supply was intact, that drainage was free and that over-distension of the loops had not occurred. The loops were excised, opened along the antimesenteric border and the length was measured in centimetres. The fluid remaining in the reservoir beaker and drained from the loops was measured and compared with the fluid volume calculated from the PSP data. These two volumes were usually within 1 or 2 ml. of one another. Sections of the loops were taken from representative animals for histological examination. These showed no histological abnormalities.

The data as shown in the figure indicated that in the cholera group the mean *d*-glucose absorption was 0·038 ± 0·003 (*SEM*) mM/cm/4 h, as compared with 0·033 ± 0·003 (*SEM*) mM/cm/4 h in the control group. The mean net fluid production in the cholera group was 2·438 ± 0·122 (*SEM*) ml./cm/4 h as compared with the mean net fluid absorption of 0·312 ± 0·062 ml./cm/4 h in the control group.

In the control experiments, absorption of glucose was accompanied by net fluid absorption. On the other hand, in the loops treated with toxin equal glucose absorption occurred despite the production of copious quantities of isotonic fluid.

These studies indicate that the rate of jejunal glucose absorption is unaltered by profuse cholera toxin induced diarrhoea. It is suggested that cholera diarrhoea results from increased secretion by the intestine rather than by any alteration of intestinal absorption, supporting the hypothesis initially proposed by Cohnheim[10].

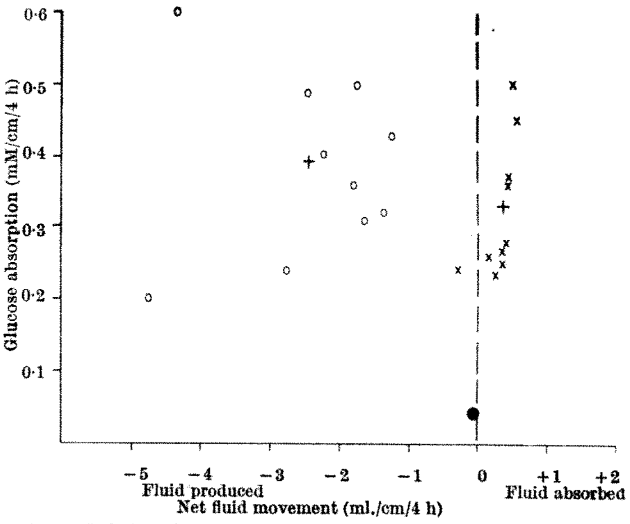

Fig. 1. Relationship between glucose absorption and net fluid movement in control and cholera toxin treated rabbit jejunal loops. Glucose absorption in mM/cm/4 h is plotted along the vertical axis and net fluid movement ml./cm/4 h along the horizontal axis. ○, Cholera loop; ×, control loop.

We thank Miss Evelyn Luebbers for technical assistance and Dr Charles C. J. Carpenter for the toxin. This work was supported in part by grants from the US Public Health Service.

PHYSIOLOGY

Inactivation of Isoniazid in Burmese Subjects

INACTIVATION by acetylation of the anti-tuberculosis drug isoniazid *in vivo* is subject to genetic polymorphism[1–3]. Studies of the gene frequency for rapid inactivation in different regions have revealed considerable racial variations[4–7]. Because of the association of isoniazid neuropathy with slow inactivation of the drug in therapeutic practice[8,9], the recording of gene frequencies among different races and in different countries is of practical importance. It is also of ethnological value in studies of population migrations. This communication reports such an investigation among Burmese subjects.

Isoniazid (10 mg/kg orally) was administered to 121 Burmese subjects, seventy-nine males and forty-two females, aged between 18 and 38. Venous blood samples were taken 6 h later, the serum was separated and extracted and the concentration of isoniazid was estimated by a vanillin condensation method[10]. Internal standards were added to serum taken from untreated subjects. The distribution of concentrations found (Fig. 1) was bimodal with an antimode at 3 μg/ml. Calculation on the basis of the seventy-six rapid and forty-five slow inactivators thus separated yields a gene frequency of 0·390 for rapid inactivation. A scatter diagram on a logarithmic scale (Fig. 2) suggested that eighteen of the rapid inactivators were homozygotes and the remaining fifty-eight heterozygotes. This distribution yields a gene frequency for rapid inactivation of 0·388 (Chi squared = 0·0094, $P > 0{\cdot}99$).

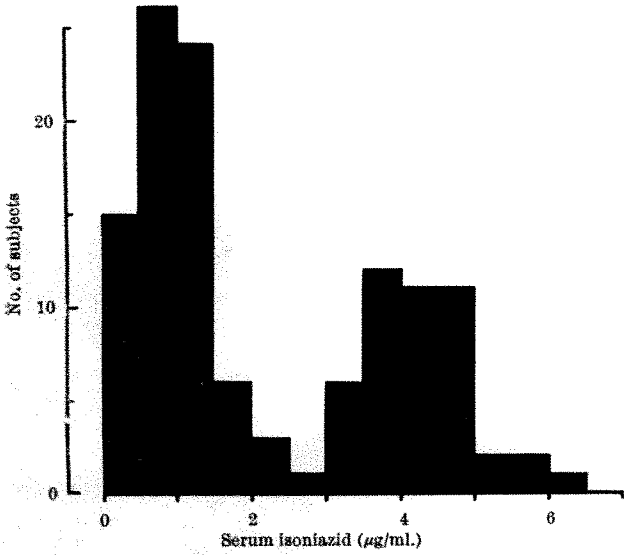

Fig. 1. Distribution of serum isoniazid concentrations in 121 Burmese subjects, 6 h after oral dose of 10 mg/kg.

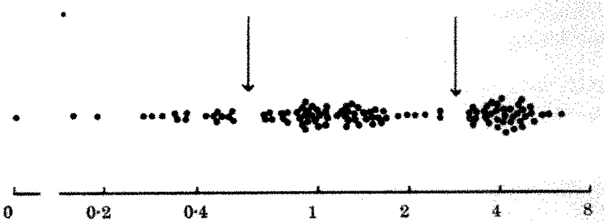

Fig. 2. Scatter diagram of serum isoniazid concentrations in 121 Burmese subjects, 6 h after oral dose of 10 mg/kg.

The gene frequency found indicates that approximately 37 per cent of Burmese subjects would carry the risk of neuropathy if clinically treated with isoniazid. This frequency is intermediate between those found among Thai[5] and South Indian[6] subjects, as might be expected both geographically and ethnologically (Table 1). The results of the present investigation are therefore consistent with current opinion of the Mongoloid origin of the gene responsible for the hepatic acetyltransferase involved.

Neurotrophic Control of Contracture in Slow Muscle Fibres

SOME frog muscles, such as the iliofibularis, contain two types of muscle fibres: the "slow" fibres, with multiple innervations by small nerve fibres and capable of producing a maintained contracture when depolarized; and the "twitch" fibres which respond normally with a transient contracture and are innervated by larger motor nerve fibres[1,2]. Contracture characteristics of these muscle fibres seem to be determined by the type of innervation they receive, because the iliofibularis muscle loses its prolonged contracture after its original innervation has been replaced by the nerve to the sartorius, which is a purely twitch muscle[3].

To further investigate this problem we decided to see what would happen if the denervated iliofibularis muscle was re-innervated by a mixed nerve, containing large and small motor axons. It is known[4,5] that after nerve section the large motor fibres degenerate more rapidly than the small ones, and conceivably regeneration of the large fibres might also be faster. Furthermore, the proportion of large motor fibres far exceeds the small ones. It was therefore anticipated that by simply cutting the sciatic nerve and allowing it to regenerate, the slow muscle fibres might well become re-innervated by the more abundant, and presumably faster growing, large axons—a supposition which seems to be correct.

Iliofibularis muscles were examined at different times after section of the sciatic nerve. The muscle from the opposite leg was used as a control. The mechanical response of the normal iliofibularis to prolonged application of acetylcholine (about 10^{-5} g/ml.) or high K solution (50 or 100 mM) consists of two phases: a transient one resulting from activation of twitch fibres, and a more prolonged contracture caused by activation of the slow fibres[2]. If the nerve was prevented from growing back to the iliofibularis, the denervated muscles gave a well maintained contracture, in response to acetylcholine or K, during the first 3 months after denervation. If, however, denervation lasted more than 4 months (at 19°–20° C), the muscles atrophied and the maintained contracture was reduced, or even lost, in some cases. The explanation for this may be that an influence from the small nerve fibres usually conveys to slow fibres their ability to give a sustained contracture, and that this is lost when the neural influence is withdrawn for a sufficiently long time.

If nerve regeneration was allowed to occur the iliofibularis became re-innervated in 1–3 months (frogs kept at 10°–15° C), and when exposed to acetylcholine or high K gave only a transient contracture. That this loss of contracture is caused by the regenerating nerve fibres and is not simply a result of denervation alone is indicated by the fact that other muscles in the same frog, like the semitendinosus, had not yet been re-innervated and still responded with a maintained contracture. Furthermore, after crushing the sciatic nerve, regeneration is more rapid and the maintained contracture is lost in only 2 weeks; while the transformation caused by denervation alone occurs much later.

The loss of the sustained contracture in re-innervated muscles cannot be attributed either to degeneration, or to recognizable structural changes of the slow muscle fibres, because these could still be distinguished under the electron microscope. Furthermore, we have electron microscopic evidence that nerve fibres had reached the slow muscle fibres and formed new neuromuscular connexions. It is interesting that the muscle membrane at the new junctions had synaptic folds. This suggests that the nerve fibres forming the new contacts were large nerve fibres, originally connected to twitch muscle fibres; and that these nerve fibres induce in the muscle fibre the formation of synaptic folds which are usually absent in slow muscle fibres.

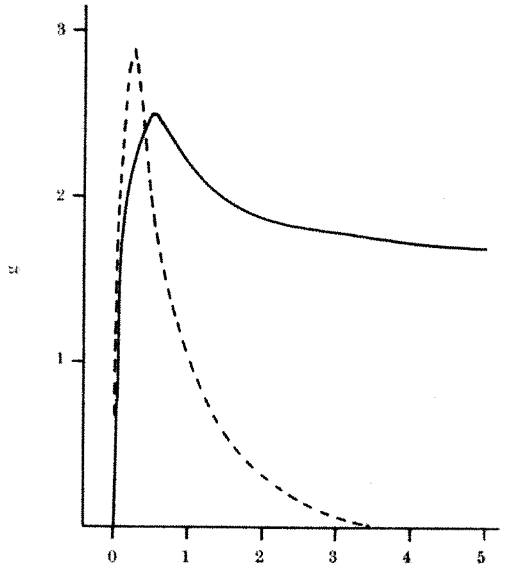

Fig. 1. Isometric contractures evoked by acetylcholine (5×10^{-6} g/ml.) in an iliofibularis 49 days after the sciatic nerve had been cut and allowed to regenerate (interrupted line); and in the control muscle in the opposite leg (solid line). The maintained contracture was already lost in the operated side even though neuromuscular transmission had not yet been restored. Frog kept at 10°–15° C after the operation.

In most respects the present results are similar to those obtained previously[3] with transplantation of the muscle, and re-innervation by the fast sartorius nerve; they confirm also that the slow muscle fibres retain their characteristic fine structural features, even though the contracture has been transformed.

An interesting new observation was the finding that muscle responses could be transformed even before neuromuscular transmission was restored as shown, for example, in Fig. 1. Similar results were obtained in several other muscles, 50–100 days after nerve section. Intracellular recording from end-plate regions showed no sign of re-innervation; and stimulation of the nerve did not elicit an electrical or mechanical response in the muscle fibres. It could be thought that the change in the duration of the contracture is accomplished even before the growing nerve fibres reach the muscle. To investigate this problem the iliofibularis nerve was dissected as it entered the muscle and examined under the electron microscope. Some Schwann cells could be seen among the still degenerating myelinated fibres. These cells contained filaments and a large number of microtubules, and were divided into several compartments all enclosed in a common basement membrane. During this, presumably early, stage of regeneration it was very difficult to ascertain whether any one of the profiles within the basement membrane was an axon or simply a process of the Schwann cell. Nevertheless, a few axons were in a more advanced stage of regeneration and could be recognized as such because they had the spiral beginnings of myelin formation. Thus it seemed that nerve fibres had definitely reached the muscle.

Fast or slow mammalian muscle can be partly converted to the opposite type when it is cross-innervated[6]. These muscles are subjected to different patterns of activity and it is not yet clear what significance, if any, the activity has in determining the type of contraction[6–9]. In our experiments activity can be ruled out as the determining factor because the contracture was changed before the transmission of impulses was restored.

These findings are of interest because they indicate, once again, that nerves are not limited simply to relaying electrical signals to the muscle, but also exert a direct influence which controls the characteristics of the contracture. They show further that the neural control is not dependent on nerve muscle impulses. The situation is somewhat analogous to the acetylcholine sensitivity of the muscle which is under a similar neural influence controlling the number and spread of acetylcholine receptors[10]. This analogy suggests also a possible way of explaining our results. It may be that there are Ca-receptors in the muscle fibre membranes, and that the number of receptors is controlled by a substance released by the nerve. To give a prolonged contracture a muscle fibre would require a high density of receptors in its membrane to supply the calcium necessary for contraction.

Abnormalities in the Electrocardiograms of Young Sheep and Lambs grazing Natural Pastures low in Selenium

FRASER and I[1,2] have previously shown that abnormalities develop after a few weeks in the electrocardiograms of both rats and lambs fed dystrophogenic diets in experimental conditions. These abnormalities can be prevented by the administration of adequate selenium or tocopherol. Without such supplementation the rats die with hepatic necrosis, while the lambs develop lesions typical of white muscle disease (WMD) which in these experimental conditions always proves fatal

In an earlier communication[3], in which I reported abnormalities in the electrocardiograms of lambs in experimental conditions, I said: "It remains to be seen whether the same type of electrocardiogram change occurs in 'white muscle disease', a malady of sheep that are grazed in particular areas and which responds to selenium therapy". These experimental studies are open to the criticism that the lambs were being fed a somewhat unnatural diet, because the protein component was supplied as torula yeast.

I have now been able to examine electrocardiogram traces of young sheep and lambs grazing pastures which are demonstrably low in selenium, and in some cases of animals which have, at subsequent necropsy, shown lesions typical of WMD.

The findings are reported in summary in this communication for two reasons: first, to meet the criticism that electrocardiogram changes are found only in the unnatural conditions associated with the feeding of torula yeast-type diets, and second, to suggest that electrocardiogram records in field cases of muscular dystrophy might, at times, be a very useful method of early detection of the condition in a flock.

During this study, nine properties were visited in South Australia and one, where there was an outbreak of WMD, in Western Australia. The nine South Australian properties ranged from one which was selected as having no husbandry problems (to serve as "control") to one where WMD has been seen, including several cases during this work. The remaining properties provided examples, to a varying degree of severity, of muscular dystrophy encountered in the field.

The electrocardiogram equipment used and the technique adopted has been fully described elsewhere[2,4], the only additional feature of these studies being the use of a portable generator to power the electrocardiograph. It is possible with this mobile equipment to examine more than a hundred electrocardiogram patterns of sheep in a day, in field conditions.

Animals were randomly selected from the young ewes and lambs of the flock, and of those showing an abnormal electrocardiogram pattern, two or three were selected for slaughter. After post-mortem examination, pieces of skeletal muscle from the limbs, left and right ventricles and diaphragm were removed, fixed in buffered formalin and prepared for histological examination by paraffin embedding and staining sections with haematoxylin and eosin.

The property in Western Australia was visited during an outbreak of WMD, after several animals had died and the diagnosis made by the local veterinary officer. Thirty-eight records were obtained from this flock.

Pasture samples from the property in South Australia where WMD has been observed several times were analysed for selenium content by Watkinson's method[5]. Finally, whole blood samples were analysed for selenium from three groups of animals: (1) from an "unaffected" area in South Australia; (2) from the property in South Australia where WMD has occurred; and (3) from the property visited in Western Australia, which had a reported WMD.

Table 1 summarizes the chief findings from the properties in South Australia. The association of abnormal electrocardiogram records with histopathological lesions of myonecrosis was quite marked. Lesions were more severe in the right than the left ventricle and were always most pronounced in the skeletal muscle of the lambs. Clear cases of WMD were found in property "Gosse, K.I. II" and muscle damage was severe with advanced calcification. In such cases the diaphragm muscle is invaded by the lesion.

Table 1. ELECTROCARDIOGRAM EXAMINATION OF RANDOMLY SELECTED YOUNG SHEEP AND LAMBS ON NINE PROPERTIES IN SOUTH AUSTRALIA

Location of property	Number of animals examined	Number of abnormal electro-cardiograms	Number slaughtered	Number slaughtered with confirmed WMD
Keith I	25	5	3	3
Keith II	23	9	4	4
Keith III*	6	0	0	0
Gosse, K.I. I†	20	0	0	0
Gosse, K.I. II	21	10	5	5
Gosse, K.I. III	14	8	2	2
Karatta, K.I. I	13	1	2‡	2
Karatta, K.I. II	17	2	2	2
Karatta, K.I. III	10	1	2‡	2

K.I., Kangaroo Island.

* No husbandry problems.

† Poor flock, but there is an annual shortage of feed.

‡ The single electrocardiogram abnormality on each of the properties I and III were typical "WMD traces". The further two cases killed were showing severe arrhythmia and other mild irregularities. All cases at histological examination showed mild myonecrosis.

The electrocardiogram abnormalities were similar to those produced in the earlier experimental study, and one example with its corresponding muscle lesion is shown in Figs. 1 and 2.

Samples of pasture from property "Gosse, K.I. II" were shown to have the following range of selenium content; Yarloop clover, 0·005–0·007 p.p.m.; mixed native grasses, 0·007–0·01 p.p.m. These values are well below the levels quoted for "selenium responsive" situations in New Zealand where the threshold is considered to be 0·04 p.p.m. (ref. 6).

Whole blood selenium levels for the three groups of animals mentioned earlier gave the following range: (1) control animals from an "unaffected" area, 0·090–0·195 p.p.m. (twenty animals); (2) "Gosse K.I. II",

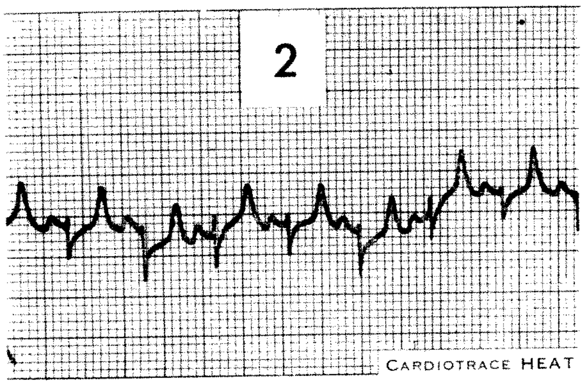

Fig. 1. Electrocardiogram record (lead II) of a lamb grazing pastures low in selenium. The animal was one of a random selection from a flock and was not clinically abnormal.

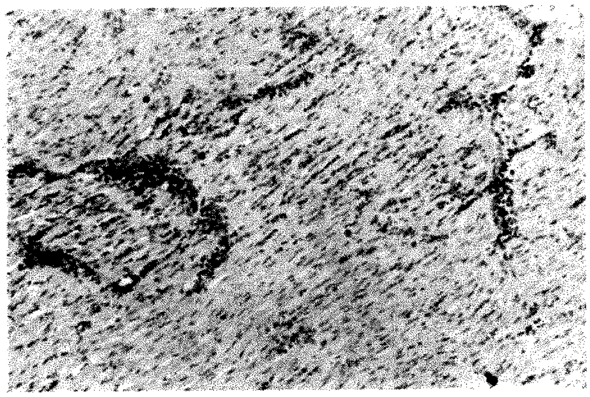

Fig. 2. Low power photomicrograph of an early lesion of myonecrosis found in the right ventricle of the lamb whose electrocardiogram is recorded in Fig. 1. Dystrophic lesions were quite widespread in the skeletal muscle of the same lamb. Stained haematoxylin and eosin. (×35.)

0·005–0·026 p.p.m. (sixteen animals); (3) "WMD flock" from Western Australia, 0·01–0·02 p.p.m. (four animals).

There is strong presumptive evidence from these findings that the electrocardiogram changes both in the field cases of muscular dystrophy and in those produced in experimental conditions have the same aetiology. In both situations the electrocardiogram patterns are similar and are associated with a low selenium intake in the lambs, which gives rise in both cases to lesions typical of WMD.

Further studies to determine whether administration of selenium can prevent the onset of these electrocardiogram changes in field cases of muscular dystrophy seem indicated. Furthermore, such studies might help to evaluate the use of the electrocardiogram as a guide in the decision to introduce prophylactic selenium treatment and in the early detection of white muscle disease.

I thank R. A. Buckley for the selenium analyses of pasture and blood samples.

Increased Receptor Utilization: Mechanism of Cocaine Potentiation

It has been known for more than 50 yr that cocaine causes potentiation of adrenergic responses. Several theories have been advanced to explain this phenomenon, but only two are ever given much attention. It has been suggested that cocaine blocks the site of noradrenaline (NA) uptake so that a higher concentration of NA is available at the receptors, resulting in potentiated responses[1]. On the other hand, some workers suggest that cocaine causes potentiation by acting on the effector cells and possibly at the α-receptors[2]. These two views are not necessarily exclusive of each other as might be inferred from some of the literature.

This work was carried out to find whether cocaine affects the receptor level or post-receptor level.

Phenoxybenzamine (POB) can irreversibly block α-receptors. It is possible, therefore, to block a sufficient number of receptors so that the maximal response to the agonist is reduced (that is, elimination of spare receptors) although the mechanical limits of the tissue have not been altered. In this case all unblocked α-receptors are assumed to be utilized in the presence of a supramaximal dose of NA. Thus the maximal response is dependent on the number of receptors remaining after POB and not on the mechanical limitations of the tissue. The maximal response of such a tissue to NA in the presence of cocaine can then only be modified by a receptor or post-receptor level mechanism.

Vasa deferentia from male albino rats were excised, trimmed and mounted in muscle baths containing Krebs-bicarbonate solution at 37° C and aerated with 95 per cent oxygen and 5 per cent carbon dioxide. Records of contraction were made isotonically (tension = 1/2 g) on a kymograph. Drug concentrations are given as the salts: noradrenaline bitartrate, cocaine hydrochloride, phenoxybenzamine hydrochloride.

After eliciting the maximum responses of the tissues by using 10^{-4} g/ml. NA, the tissues were washed and allowed to relax for 15 min at which time they were subjected to 5×10^{-9} g/ml. POB for 3 min then washed at 10 min intervals for 1·25 h. At this time the same concentration of

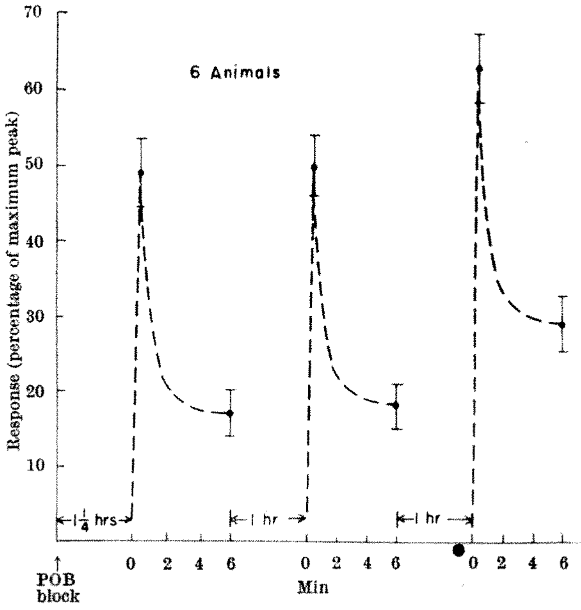

Fig. 1. Graph of mean responses of rat vas deferens in terms of the peak response to a maximal dose of noradrenaline (NA) 10^{-4} g/ml. Blockade of α-adrenergic receptors was effected 1·25 h before the graphed responses, by phenoxybenzamine, 5×10^{-9} g/ml. for 3 min. The last response was made in the presence of cocaine, 10^{-6} g/ml., added 1 min before the NA. Bars represent standard error of the mean (see Fig. 2 legend).

NA was given for 6 min, which allowed the tissue to produce a reduced rapid contraction (peak) and a steady state contraction (equilibrium) (Fig. 1). After an hour this concentration of NA was repeated and the previous response was closely reproduced (means of equilibria were within 1 per cent, Fig. 1). After another hour the tissue was treated with cocaine (10^{-6} g/ml.) 1 min before another dose of NA (10^{-4} g/ml.). The presence of cocaine increased both the maximal peaks and maximal equilibrium responses significantly ($P < 0{\cdot}01$, by paired data t test) (Fig. 1).

To ensure that the dose of NA which was supramaximal before treatment with POB was still supramaximal after, a different procedure was followed (Fig. 2). As before, the tissue maxima were obtained and POB blockade effected. After repeated washings for 1 h the tissues were subjected to 10^{-4} g/ml. NA for 6 min and then more NA was added, increasing the concentration to 2×10^{-4} g/ml., and left for another 6 min. This additional NA resulted in no change in equilibrium contraction. Subsequent addition of cocaine 6 min later, however, in the same concentration as used previously (10^{-6} g/ml.), resulted in a significant ($P < 0{\cdot}02$) increase in equilibrium within 3 or 4 min (Fig. 2).

After blockade with phenoxybenzamine it is seen that the presence of cocaine causes an increase in the maximum responses to NA. Cocaine introduced during responses to NA also causes an increased equilibrium. Because the portion of receptors remaining after POB blockade cannot produce the maximum response of which the tissue is capable, and because supramaximal doses of NA were used (no change occurred in the equilibrium with the additional NA), the increase in response in the presence of cocaine cannot be caused by increases in the local concentration of NA.

A series of six experiments similar to the first method outlined earlier was done, using methacholine instead of noradrenaline as the agonist. Only the peaks and not the peaks and equilibrium contraction (the latter are very small with methacholine) were compared. The dose of phenoxybenzamine used (5×10^{-8} g/ml. for 3 min) was sufficient to block noradrenaline by 90 per cent. Cocaine did not potentiate the peak responses to methacholine ($P > 0{\cdot}05$, paired-data t test).

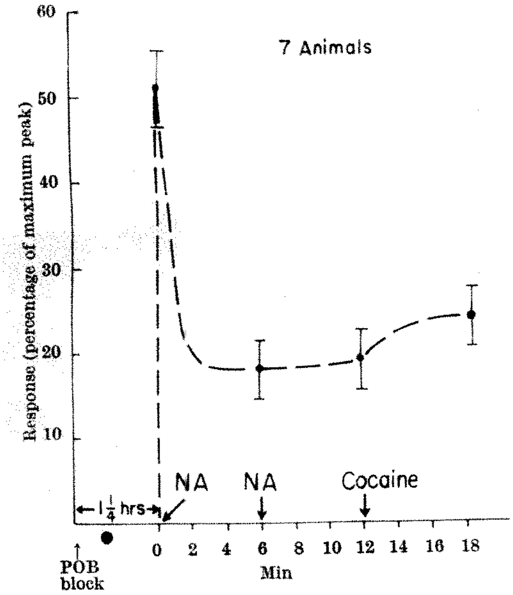

Fig. 2. Graph of mean response of rat vas deferens, in terms of the maximum peak response to noradrenaline (NA) 10^{-4} g/ml. before phenoxybenzamine blockade. POB (5×10^{-9} g/ml. for 3 min) was given 1·25 h before the responses graphed. Drugs were added in a cumulative manner. Note that, as in Fig. 1, the bars represent standard error of the means calculated on a non-paired basis, while statistical significance was assessed on a paired-data basis.

The increased responses of maximal equilibrium of these tissues can be attributed either to an increase in the effective utilization of receptors or to an increase of some post-receptor process such as excitation–contraction coupling. The process, however, by which cocaine potentiates is only involved with excitation by noradrenaline and not with excitation by methacholine, and it appears to be doubtful whether excitation–contraction coupling is involved. The increased utilization of receptors could be a result of increase of efficacy (intrinsic activity)[3]; a change in affinity would not produce any alteration of maximal response. As the response of the tissue follows qualitatively that predicted by the "rate theory of drug action"[4], we analysed our hypothesis of increased receptor utilization in terms of "rate-theory" kinetics. For the response of maximal equilibrium, Paton's equations reduce to

$$y_{\max} = \varphi \, k_2$$

where y is the equilibrium contraction, φ relates stimulation to response (and therefore includes excitation–contraction coupling) and k_2 is the dissociation or "offset" rate constant. Thus an increase in $y_{\max}$ could arise from increases in either φ or k_2. An increase in the latter appears to give a simpler solution since fewer assumptions about the process and the effects of cocaine would need to be made. It is reasonable that any interaction of cocaine near the adrenergic receptor might affect the equilibrium constant of the drug-receptor reaction. This postulated increase in k_2 would be sufficient to explain potentiation at any dose of noradrenaline. According to Paton's hypothesis, the equilibrium is limited by the availability of receptors for combination of the drug, and receptor availability depends on dissociation of existing complexes of drug receptor. An increase in k_2 would thus increase receptor availability, increase the combination rate of drug-receptor and potentiate the height of the equilibrium. The peak should also be potentiated since an increase in k_2 would slow development of fade.

It is seen that the maximal equilibrium attained in Fig. 2 is less than that of Fig. 1. This can be attributed either to protection of receptors by NA, which may interfere with the combination of cocaine–receptor, or inability of the tissue to respond further as a result of the prolonged exposure to high concentrations of NA.

Normocalcaemia in relation to Cortisone Secretion

THE hypercalcaemia which occurs in adrenalectomized animals or in patients with Cushing's disease treated by subtotal adrenalectomy has been thought to be the result of antagonism between secretions from the adrenal gland and parathyroid hormone[1]. Because cortisone produces hypocalcaemia, this hormone was thought to be the adrenal factor that influenced calcium homeostasis. A brief review of the history of these findings was given by Myers *et al.*[2], who investigated the subject further in adult adrenalectomized dogs. They reported the development of hypercalcaemia in these animals when cortisone therapy was withdrawn; however, subsequent thyroparathyroidectomy of the animals failed to prevent the hypercalcaemia of adrenal insufficiency. Our attention was caught by the fact that the dogs studied by Myers *et al.* lacked secretions from both the thyroids and the parathyroids. It has been shown that thyroxine and calcitonin, both coming from the thyroid gland, are important in mineral metabolism[3,4]. This report describes the results of a study designed to find out whether secretions from the thyroid, alone or in conjunction with parathyroid hormone, are important in the development of the hypercalcaemia of cortisone lack.

Adult mongrel dogs were divided into three groups of seven to thirteen animals each. In group 1, both thyroids and parathyroids were removed; the serum calcium and thyroxine levels decreased to values expected in thyroparathyroidectomized animals (serum calcium $< 6 \cdot 9$ mg/100 ml., serum thyroxine $< 1 \cdot 5$ μg/100 ml.). In group 2, the thyroids were removed but the superior parathyroids were left intact; the thyroxine levels decreased to thyroidectomy levels (serum thyroxine $< 1 \cdot 5$ μg/100 ml.) and the serum calcium values remained normal (serum calcium $> 9 \cdot 4$ mg/100 ml.). In group 3, the parathyroids were removed but the thyroids were left; the serum calcium levels decreased while thyroxine values remained normal (serum thyroxine $> 3 \cdot 5$ μg/100 ml.). Total adrenalectomy was done after neck surgery, generally 12 to 30 days later; however, in group 2, the adrenals were removed between 48 and 207 days after thyroidectomy. In all animals, 500 mg of sodium chloride per day and 5 mg of desoxycorticosterone ('Percorten') every 30 days were given throughout the experiment so that only corticosteroids were absent. Immediately before and for 3 days after adrenalectomy, prednisolone sodium phosphate was given until recovery from the operation was complete. The animals without parathyroids were maintained on a high-calcium diet until the adrenalectomy.

Fig. 1 shows the changes in serum calcium values after adrenalectomy, 100 per cent being the serum calcium value 3 days after cessation of corticosteroid replacement therapy. These values are corrected for specific gravity according to the method of Dent[5] and represent the mean values of the dogs in each group. The standard errors about each point in Fig. 1 are in all instances less than 20 per cent and the differences between curves are significant ($P < 0 \cdot 01$). Parathyroidectomy alone seemed to result in a precipitous increase in serum calcium, the animals dying as values of 17 mg/100 ml. or greater were reached unless the serum calcium was decreased by administration of corticosteroid. In the thyroidectomized animals there was little change in the serum calcium level, while the thyroparathyroidectomized animals showed a response midway between that of the two other groups.

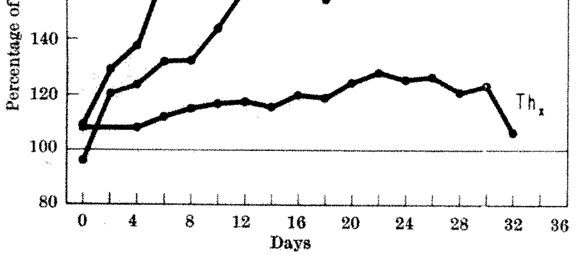

Fig. 1. Changes in serum calcium in adrenalectomized dogs which had been parathyroidectomized (Pth_x), thyroidectomized (Th_x), or thyroparathyroidectomized (Pth_xTh_x). Values are expressed in percentages of the postadrenalectomy serum calcium levels.

Feeding a diet deficient in calcium to these animals failed to prevent the hypercalcaemia, as shown by Walser *et al.*[6], although there appeared to be some delay in the initial development of hypercalcaemia. This suggested that absorption of calcium from the diet was not an important factor in the development of the hypercalcaemia. The alternative source of calcium is, of course, the skeleton. The animals showing hypercalcaemia demonstrated an increase, by a factor of three, in the amount of bone resorption taking place compared with normal cortical bone; most of the resorption occurred on the periosteal surface of bone.

The increase in serum calcium was accompanied by a decrease in the *p*H of the serum; at a serum calcium level of 10·0 mg/100 ml. the *p*H was approximately 7·30, and when the serum calcium was greater than 16·0 mg/100 ml. the *p*H was less than 7·28. In one dog, infusion of a solution of 1 per cent sodium hydroxide in 50 ml. of isotonic saline caused the *p*H to increase from 7·30 to 7·52 and the serum calcium to decrease from 15·4 to 13·5 mg/100 ml. These data suggested that changes in *p*H are important; in this context both Myers *et al.*[2] and Walser *et al.*[6] demonstrated an increase in plasma proteins and citric acid and a decrease in plasma bicarbonate. Both groups of investigators thought that only a small part of the hypercalcaemia could be related to the increase in serum proteins, while the latter group thought that an increase in the calcium-binding capacity of the protein might be an important factor. It is possible that the chief result of cortisone lack is to decrease blood *p*H and that bone acts as a buffer, releasing calcium into the blood. The buffering action seems to be more important physiologically than the control of serum calcium levels.

The failure of the thyroidectomized animals to show significant hypercalcaemia is related to the role of thyroxine in maintaining cell activity. This group of animals had been thyroidectomized for an average of 3 months before adrenalectomy, in contrast to the thyroparathyroidectomized animals which had undergone neck surgery only 12 to 30 days before adrenalectomy. The long-term absence of the thyroids ensured that the bone was in a hypothyroid state. Although the effect of cortisone lack appeared to be the same as far as *p*H changes were concerned, the serum calcium failed to increase. Administration of thyroxine to two thyroidectomized animals in this group produced a dramatic hypercalcaemia, the serum calcium increasing from 10·0 to 17·0 mg/100 ml. in 3 days. This observation both explains the difference between the groups and stresses the importance of thyroxine in maintaining normal cell metabolism. The difference between the thyroparathyroidectomized animals and the parathyroidectomized animals probably can be explained by a partial response of the bone to lack of thyroid hormones (partial because the period of hormonal lack was short). Calcitonin seems to be unimportant because thyroxine alone restored the response of the bone to hypocortisonism and produced hypercalcaemia.

These investigations will be incomplete until the mechanism explaining the hypercalcaemia of cortisone lack is clear. It is perhaps relevant, but more confusing, to remark that one of the main effects of cortisone in man, rats and rabbits seems to be the resorption of bone[6,7]. In fact, the osteoporosis of hypercortisonism is a rapidly developing bone disease, although it is not associated with hypercalcaemia[8]. Whatever the final explanation is, this report demonstrates the importance of the corticosteroids in maintaining normocalcaemia and also indicates that the hypercalcaemia of hypocortisonism seems to be independent of the parathyroids and to depend only on the presence of adequate amounts of thyroxine. The importance of thyroxine seems to be in maintaining the bone in a state in which it is able to respond by releasing calcium.

This investigation was supported in part by a research grant from the National Institutes of Health, US Public Health Service.

Correlation of Loss of Hyaluronic Acid and Chondroitin Sulphate in Skin of Mice with Carcass Nitrogen Loss during Starvation

THE constituents of the ground substance of connective tissue respond dynamically to loss of systemic nitrogen. Marked changes have been reported to occur in the composition of the skin of mice during starvation[1]. This is accompanied by a significant reduction in hyaluronic acid (HA) and chondroitin sulphate (CS). Earlier studies[2] with rats suggested that hexosamine-containing materials in the skin decreased rapidly with small losses of carcass nitrogen (N), but when large losses occurred the additional decrement in the former was small. No attempt, however, was made to quantitate this relationship. In this work, decrement in HA and CS during starvation was correlated with loss of N in mice.

The procedures used were essentially those which have been described before[3,4]. In accordance with the general plan the quantities of HA and CS in the total pelt were determined and total N was measured in the carcass which remained after skinning. The length of the femur was measured to serve as a function of maximum growth. Regressions were derived correlating HA, CS and N with femur length in normal mice. In the starved mice, the quantity of HA, CS and N which were present before starvation could then be calculated from these regressions and the actual loss determined, using the observed values.

In order to establish the normal regressions twenty-seven male mice, weighing 24·0–40·3 g, were used. During starvation sixty-seven male mice, weighing 26–32 g, were individually housed in plastic containers (7 × 5 × 2·5 in.) on a layer of sawdust. Water was freely available. About ten mice were killed each day so that all had been killed after 7 days of starvation.

After cervical fracture the femurs were everted in a uniform manner and an X-ray picture was taken to be used for measurement of femur length. The pelt was removed in a uniform manner, dehaired, scraped free of subcutaneous tissue and analysed for HA hexosamine (HAH) and CS hexosamine (CSH) and the carcass was dissolved in formic acid ready for nitrogen analysis.

The regressions correlating HAH, CSH and N with femur length are as follows

$$\ln \mathrm{N} = 4{\cdot}97133 + 3{\cdot}75669 \ln F, r = 0{\cdot}871, P < 0{\cdot}001 \quad \text{(Fig. 1}a\text{)}$$

$$\ln \mathrm{HAH} = 3{\cdot}85427 + 5{\cdot}14034 \ln F, r = 0{\cdot}714, P < 0{\cdot}01 \quad \text{(Fig. 1}b\text{)}$$

$$\ln \mathrm{CSH} = 3{\cdot}71406 + 3{\cdot}77380 \ln F, r = 0{\cdot}598, P < 0{\cdot}01 \quad \text{(Fig. 1}c\text{)}$$

where N is mg of carcass nitrogen, HAH is µg of hyaluronic acid hexosamine, CSH is µg of chondroitin sulphate hexosamine, F is femur length in cm and r is the correlation coefficient. The high statistical significance is apparent.

From the femur length the pre-starvation values of HAH, CSH and N were calculated. Using the observed values, loss of HAH (ΔHAH), CSH (ΔCSH) and N (ΔN) were then obtained.

The data were correlated as $\ln \dfrac{\Delta\mathrm{HAH}}{\Delta\mathrm{N}}$ and $\ln \dfrac{\Delta\mathrm{CSH}}{\Delta\mathrm{N}}$ regressions on ln ΔN with high correlation coefficients and statistical significance as follows

$$\ln \frac{\Delta\mathrm{HAH}}{\Delta\mathrm{N}} = 3{\cdot}52280 - 0{\cdot}74516 \ln \Delta\mathrm{N}, n = 67, \quad r = 0{\cdot}799, \; P < 0{\cdot}001$$

$$\ln \frac{\Delta\mathrm{CSH}}{\Delta\mathrm{N}} = 2{\cdot}88043 - 0{\cdot}84072 \ln \Delta\mathrm{N}, \quad n = 43, r = 0{\cdot}704, \; P < 0{\cdot}01$$

Arithmetic or semi-logarithmic relationships were inadequately correlated. Written in exponential form

$$\frac{\Delta\mathrm{HAH}}{\Delta\mathrm{N}} = \mathrm{Constant}/\Delta\mathrm{N}^{0{\cdot}74516} \text{ and}$$

$$\frac{\Delta\mathrm{CSH}}{\Delta\mathrm{N}} = \mathrm{Constant}/\Delta\mathrm{N}^{0{\cdot}84072}$$

It is apparent that $\dfrac{\Delta\mathrm{HAH}}{\Delta\mathrm{N}}$ and $\dfrac{\Delta\mathrm{CSH}}{\Delta\mathrm{N}}$ decline rapidly with increasing ΔN. The reasons for this are not apparent, but several possibilities are suggested. These include (*a*) reduced rate of synthesis of fibroblast-produced substances during starvation in order to conserve materials and energy stores, and (*b*) release of protein present in the ground substance in order to conserve protein in the more vital organ. The ground substance contains plasma proteins as well as proteins, glycopeptides and mucoproteins synthesized by the fibroblasts and possibly other local cells. It was suggested earlier that in a restricted sense ground substance may serve as a protein storage site[2]. Although plasma proteins are "excluded" from hyaluronic acid gels according to the principles of gel filtration[5] the extracellular fluid-ground substance contains a considerable portion of plasma proteins, as much as half of the plasma albumin[6]. The protein in this phase suffers considerable reduction during starvation[1]. The nature of this feedback mechanism deserves intensive investigation.

The findings suggest a clinical application. Because collagen in the skin is relatively stable, the decline in hyaluronic acid/collagen in skin biopsies should follow loss of nitrogen during debilitating circumstances. This ratio has been measured in 8 mm punch biopsies taken during surgery and after realimentation and the difference has been correlated with loss of nitrogen during the period (unpublished work of Sobel and Cincotti).

Action of Insulin on Sodium Efflux from the Toad Oocyte

INSULIN applied *in vitro* reduces the internal sodium concentration of rat skeletal muscle[1-3] and stimulates the active transport of sodium in sodium-loaded frog muscle[3] and in toad bladder[4]. External application of insulin to single crab muscle fibres *in vitro* can cause a striking rise in the efflux of sodium[5]. Insulin stimulates protein synthesis in skeletal muscle in the presence of actinomycin D[6,7] and, because it has been shown that this inhibitor does not stop the hormone from stimulating the sodium pump[5], it is difficult to decide whether the primary action is on the efflux mechanism or induction of *de novo* protein synthesis. This communication describes the behaviour of another single symmetric cell, the toad oocyte, towards insulin.

Immature oocytes were obtained from the ovaries of healthy specimens of *Bufo bufo* by treatment with 0·5 per cent trypsin or by dissection. The methods employed for counting the sodium-24 activity of single cells and the effluent and the compositions of the Ringer and trypsin solutions used were those given by Dick and Lea[8] as modified by Bittar, Dick and Fry[9].

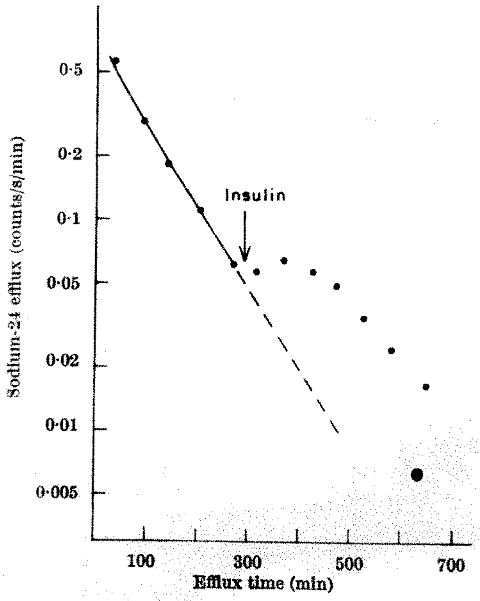

Fig. 1. The effect of 0·1 U/ml. of insulin on sodium efflux in a trypsinized oocyte (semi-log plot).

Normal dissected oocytes were insensitive to insulin: none of the twenty-four oocytes tested with 0·1 U/ml. of insulin showed a response, neither was any effect observed in four cells treated with 1 U/ml. of insulin, as compared with untreated controls. Occasional responses occurred in three different experimental conditions. First, three out of twenty oocytes pretreated with trypsin responded to 0·1 U/ml. of insulin by showing a prompt and significant rise in the efflux (Fig. 1). Second, six oocytes, from the same ovary, treated overnight with 20 μg/ml. of actinomycin *D*, showed a response like that in Fig. 2. (There was no evidence from control cells that actinomycin *D* influenced the behaviour of the efflux.) Third, two of a batch of four oocytes from the same ovary, sodium-loaded by cooling to approximately 4° C overnight, showed definite effects illustrated by Fig. 3. The sodium content of all these cells was between three and four times the normal of 10 mM/l. Twenty-six oocytes, sodium-loaded by overnight cooling, failed to respond to insulin, however, so factors besides a rise in the internal sodium must govern the response to insulin.

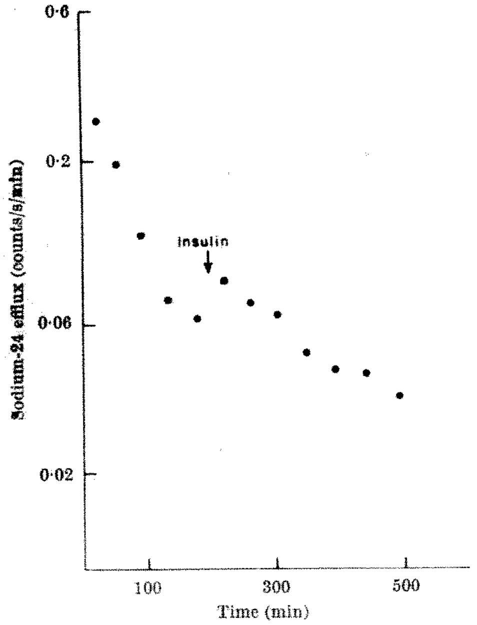

Fig. 2. Action of 0·1 U/ml. insulin on an oocyte treated with actinomycin. The oocyte had been exposed to 20 μg/ml. of actinomycin throughout the periods of sodium-24 loading and testing (that is, some 16 h).

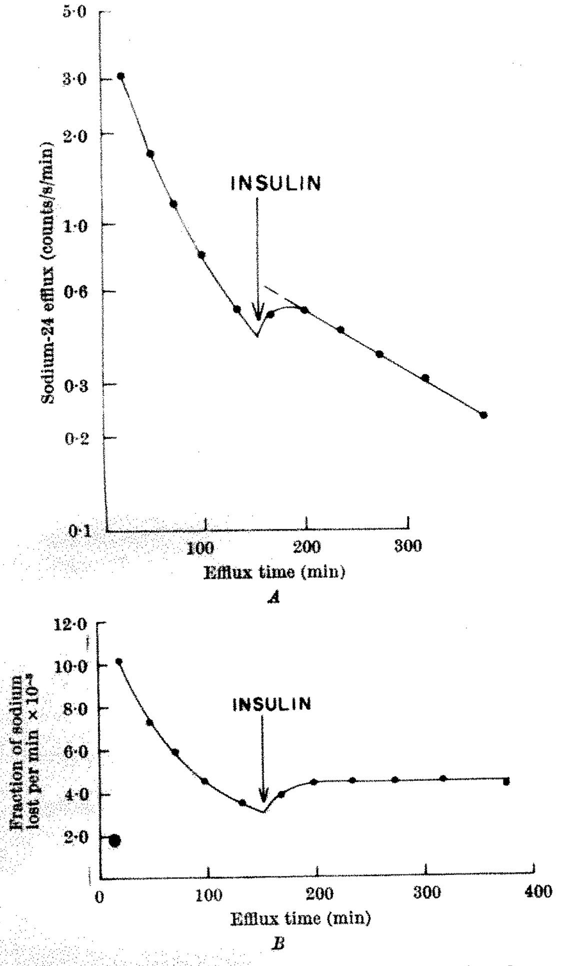

Fig. 3. The effect of 0·1 U/ml. of insulin on sodium-24 loss from an oocyte loaded with radio-sodium at an environmental temperature of about 4° C. *A*, The efflux curve; *B*, the rate constant curve.

The responses when they occurred were similar, despite differences in experimental conditions. The kinetics do not seem to fall into a simple pattern, however, because insulin increases the efflux of radio-sodium (Fig. 3*A*) and decreases its rate of decline. Also, in the presence of insulin, the fraction of sodium lost each minute becomes constant (Fig. 3*B*). The hormone probably acts by releasing sequestered sodium in some cells in which the rate of exchange between this and free intracellular sodium is slow. Response in actinomycin-treated oocytes implies that the action of the hormone does not depend on RNA synthesis. This is supported by the fact that actinomycin *D* is able to penetrate the oocyte[10] and abolish RNA formation in the resting cell[11].

Effect of Heparin on Serum Calcium Concentrations in Mice

A HYPOCALCAEMIA induced by heparin has been the subject of several recent publications. In 1961 Heidland *et al.*[1] showed that a single intravenous injection of heparin elicited a significant lowering of serum calcium in dogs and they attributed this effect to the formation of a heparin–calcium complex in the serum. Goldsmith and Parry[2] also demonstrated heparin-induced hypocalcaemia in rabbits, and to a lesser extent in rats. The following mechanism for the phenomenon was suggested: heparin activates lipoprotein lipase with a resulting release of free

fatty acids and subsequent formation of their insoluble calcium salts.

Because of the increasing use of heparinized blood from the laboratory mouse in studies of calcium homoeostasis, we have investigated the effect of a single intramuscular injection of heparin on serum calcium concentrations in mice.

Three hundred Swiss albino mice (60–90 days old) of both sexes weighing 25–30 g were randomly assigned to four experimental groups. Groups 1, 2 and 3 received 0·25, 0·50 and 2·0 mg of heparin, respectively; group 4, the control, received 0·5 ml. of isotonic saline. Two commercial heparin sources containing no detectable calcium (Wyeth, 100 USP units/mg, and Sigma, 160 and 170 USP units/mg) were used with no apparent difference in degree of hypocalcaemia. In all cases a single intramuscular injection with a total volume of 0·5 ml. was administered. Blood was collected by cardiac puncture and the serum was analysed for calcium 2 h after injection by the Mager–Farese[3] modification of the glyoxal *bis* (2-hydroxyanil) reaction[4]. All haemolysed sera were discarded. The results (Table 1) were analysed by a completely randomized design test. Treatment means were analysed by Student's t test when the calculated F ratio was shown to be significant. A 0·01 level of rejection was used. All the groups injected with heparin exhibited a statistically significant decrease in serum calcium when compared with controls, but no apparent dose response could be demonstrated.

In view of these findings, we recommend that caution be exercised in the utilization of heparin as an anticoagulant agent in studies concerning serum calcium.

BIOLOGY

Success of Eggs of the Shag on the Farne Islands, Northumberland, in relation to their Content of Dieldrin and *pp*'DDE

RECENT declines in the density and productivity of bird-eating predators, for example, the peregrine (*Falco peregrinus*) and sparrow hawk (*Accipiter nisus*), have been attributed to the presence of organochlorine pesticides in the tissues and eggs of these birds[1,2]. It has been suggested that the lethal dose in adults of these species resulted from the ingestion of contaminated grain-eating prey[3]. Granivorous birds, especially the wood pigeon (*Columba palumbus*), suffered considerable mortality in the period 1956–1961 when they ingested organochlorine seed dressings of the cyclodiene type, during spring sowing programmes[4,5].

Sub-lethal effects and effects on reproduction are more difficult to assess. Recent attempts[6-8] to compare the concentrations of organochlorines in eggs with their success have been thwarted by the scarcity of predators so that the sample sizes are inadequate for critical analysis. Comparable investigations in North America[9,10] are chiefly concerned with DDT which is only occasionally found in analytically significant amounts in the eggs of birds in the British Isles[11].

The concentrations of the organochlorine compounds in the eggs of the shag (*Phalacrocorax aristotelis*) from colonies on the Farne Islands, Northumberland, are higher than in other species of sea birds, except for the relatively non-toxic *pp*'DDE which is higher ($P<0\cdot01$) in the cormorant (*Phalacrocorax carbo*)[12]. The concentration of organochlorine insecticide in shag eggs, excluding *pp*'DDE, is similar to that recorded in the peregrine in which toxic effects have been claimed[2,13].

This report is based on analyses of shag eggs from the Farne Islands in each of the four seasons 1964–1967; the methods are described elsewhere[12]. The analyses were carried out by Shell Research Limited, Sittingbourne, Kent. Eggs were taken under licence, both at random and (most of them) by collecting addled (non-hatching) eggs. It is necessary to correct the concentration of insecticide in eggs to allow for water loss through evaporation, particularly because fertile and infertile eggs lose water and also carbon dioxide at different rates[14] and because more than 10 per cent of the addled eggs had extensive hair cracks through which water loss could occur. Where possible, egg or chick losses caused by inclement weather, predation and so on are excluded from this study. Success of the clutch or survival of the eggs and chicks was considered from the onset of incubation to the tenth day after hatching—a period of about 6 weeks. Earlier work has shown that the concentration of organochlorine insecticides in an individual shag declines from the time that it is first fed, so that at the tenth day the level is less than half that on hatching[12].

The within clutch variation in concentration of organochlorine is significantly less than the between clutch variation ($P<0\cdot001$; for example, twenty-one eggs of seven clutches, $F=10\cdot2$, for dieldrin). One egg of a clutch can therefore be taken as representative of the others. Embryo mortality was low, for only 17 per cent of addled eggs contained dead embryos. The "benefit of the doubt" was therefore given to live embryos in well incubated eggs collected at random. This method allows the consideration of addled eggs among the sample collected at random but means that the brood size is overestimated. A sample of 151 eggs were assayed from the 118 clutches which were selected for this study; the clutches contained 357 eggs.

There is no significant correlation between clutch size or brood size and the concentrations of either *pp*'DDE or dieldrin (Table 1). Total clutch or brood failure is not correlated with the concentrations of *pp*'DDE, which is usually considered much less toxic than dieldrin, but

Table 1. SUCCESS OF SHAG CLUTCHES FROM THE FARNE ISLANDS, NORTHUMBERLAND, ACCORDING TO THEIR ORGANOCHLORINE CONTENT

Concentration (p.p.m. wet weight) of whole egg, including shell assuming sp. gravity of 1·0	Clutches sampled	Total eggs in the clutches	Eggs per clutch	Chicks per brood, tenth day	Percentage clutches with no chicks surviving to tenth day (± *S.E.*)

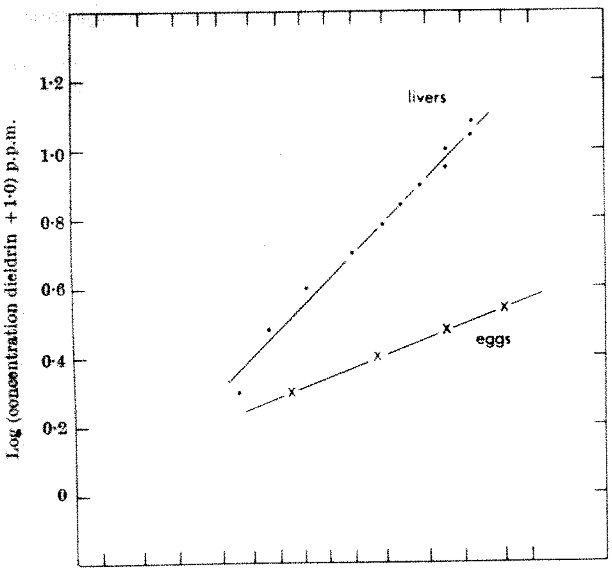

Fig. 1. Arithmetical probability plot of the accumulated log-normal frequency distribution curves of the concentrations of dieldrin in the liver and in the eggs of the shag.

there is a significant correlation ($2 \times 2\chi^2$, exact method; P (2 tail) $< 0{\cdot}04$), apparently of the threshold type, between the level of dieldrin and total clutch–brood failure. Such an association between the concentration of dieldrin and mortality is not related to parental age or experience and in any case the concentration of dieldrin in eggs is not related to the age of the female shag[12]. No investigation of the metabolism of dieldrin in birds has been carried out, but work on rabbits and rats suggests that a live embryo will break down dieldrin into its hydrophilic metabolites more quickly than substances in a "dead" egg[15,16]; however, this could not account for a correlation of a threshold type.

Laboratory studies using injection methods[17] have shown that the newly hatched chick is likely to be the stage during the development of birds which is most susceptible to dieldrin poisoning. For example, the survival of the embryo of the domestic fowl is not affected even at whole egg concentrations of 200 p.p.m. dieldrin[18], but concentrations of 17 p.p.m. in the egg can increase mortality if food shortage occurs immediately after hatching[19]. The toleration of different species of bird to dieldrin is claimed to vary three or four fold (refs. 20 and 3; compare ref. 21), but much of the work is non-critical, on a small scale and difficult to extrapolate to field conditions. It seems unlikely, however, that any poisoning occurred in the unsuccessful shag clutches which contained 2–3 p.p.m. of dieldrin because there is no evidence of an unusual proportion of deaths of chicks at hatching (Table 2).

Table 2. DETAILS OF NINE SHAG CLUTCHES CONTAINING EGGS WITH 2 P.P.M. DIELDRIN

	Whole egg conc. dieldrin (p.p.m.)	Year	Details of eggs		Total eggs
			Eggs assayed	Other eggs	
1	2·05	1967	ND, hair crack	Broken	2
2	2·08	1966	ND	ND	3
3	2·10	1965	ND	3 young > 10 days	4
4	2·10	1966	Live embryo (20 mm)	Female died, nest abandoned	4
5	2·22	19[illegible]6	Dead embryo (45 mm)	1 young died. 3 days 1 egg ND	3

8	2·65	1965	ND	Prob. ND	3
9	2·77	1965	ND	ND	2

ND, No embryonic development.
Out, Egg kicked out of nest by shags.
No. 7 is not included in Table 1; it was collected on the Isle of May, Fife, and was the only egg with > 2 p.p.m. dieldrin in a sample of twenty-eight (ten in 1965, eighteen in 1966).

It seems reasonable to consider the egg as a body "compartment"[22] and therefore to assume that the concentrations of dieldrin in other "compartments" of the laying female are correlated with that in the eggs. Analysis of the log-normal frequency distribution of concentrations of dieldrin in the livers of twenty-seven adult (of breeding age) shags and in the eggs (Fig. 1) suggest that concentrations of 2·5 p.p.m. in the egg reflect concentrations in the liver of about 9 p.p.m. A full investigation has revealed no evidence of dieldrin poisoning of adult shags from the Farne Islands[23].

The concentration of 9 p.p.m. in the liver is about one-fifth the mean concentration found in livers of experimentally poisoned quail (*Coturnix japonica*)[21], pigeons (*Columba livia var*)[5,21] and in duck poisoned with dieldrin in Colorado[24]. The sub-lethal effects of dieldrin are little known, but they have been described in the field[25,26] and in the laboratory, both *in vitro*[27] and *in vivo*[28]. Concentrations of DDT one-hundredth of the acute oral LD_{50} have been shown to increase the irritability of the central nervous system in rats dosed over a period of 30 days[28].

Recent increases of the rate of egg breaking in the sparrow hawk[29], peregrine[1,2,7] and golden eagle (*Aquila chrysaëtos*)[30] have been considered to be the result of sub-lethal effects of organochlorine insecticide contamination, and egg breaking also occurs in the shag (for example, clutches 1 and 6 in Table 2). Just over one-third of the egg breaking in the shag, and most cases of repeated breakages, were, however, the result of interference by extra females resulting from simultaneous polygyny at one nest. The survival curves of eggs of pairs and at nests with the polygyny are shown in Fig. 2. It is interesting to note that this kind of interference has been considered to be one of the causes of egg breaking in the peregrine[31]. Little is known of the causes of egg breaking in normal pairs of shags but the incidents were not related to the age or experience of the pair. Polygyny has been recorded in the shag before the use of organochlorine insecticides[32–34] and egg breaking has for long been recorded in several species[35,36].

It seems unlikely that organochlorine poisoning of embryo or chick shags has occurred on the Farne Islands and the adult mortality rate has not been increased with the use of dieldrin. On the other hand there is some evidence of a lowered breeding success among the few

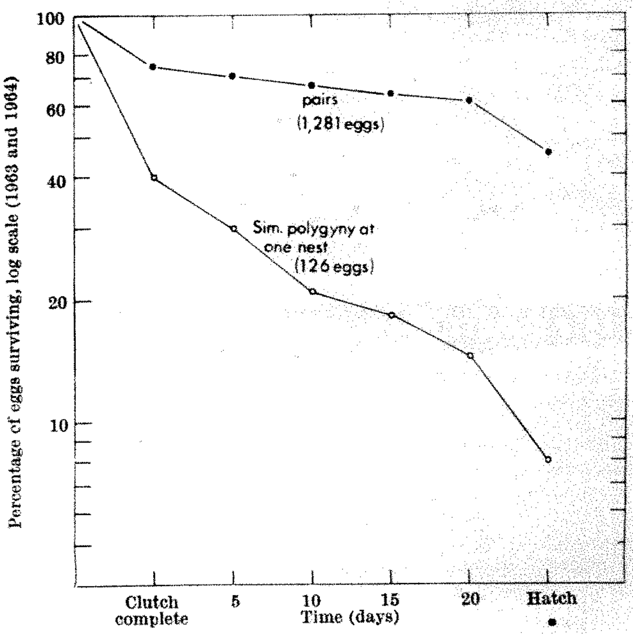

Fig. 2. Survival of eggs of the shag on the Farne Islands, Northumberland (1963 and 1964), comparing nests with normal pairs and those with simultaneous polygyny.

female shags (< 6 per cent) with liver concentrations of about 9 p.p.m. of dieldrin. It is possible that this is the result of sub-lethal effects, but much of the egg breaking is caused by polygyny. Much more detailed and critical attention than hitherto should be given to experimental studies of the sub-lethal effects of insecticides.

I thank Shell Research Limited, particularly Dr J. Robinson and A. N. Crabtree, for doing the analyses, and the Farne Islands Committee of the National Trust for permission to work on the Farne Islands. I also thank Dr N. W. Moore and Dr D. Ratcliffe of the Nature Conservancy and Dr J. C. Coulson and Dr M. Stone, University of Durham, for their help.

Discovery of *Rhabdopleura* (Hemichordata) at Plymouth

Rhabdopleura is one of three pterobranch genera which as hemichordates are important in our understanding of the evolution of the chordates[1]. Its biology and life cycle are very incompletely understood. So far, the most suitable marine laboratory for studying this genus has been Bergen, where *R. normani* has been well investigated[2]. This species, however, has to be kept at temperatures less than 12° C, and is dredged from a hard, rocky bottom in rather deep water.

The habitat of *R. normani*, the best known species, extends from within the Arctic Circle southward to the Azores, but, apart from a few records in shallow waters of some Norwegian fjords[2], it inhabits deep water, usually on the continental slope. In April 1967, specimens of *Rhabdopleura* were dredged for the first time from 1 to 2 miles south of Stoke Point in Devon. They have been identified as *R. compacta* Hincks[3], having the highly characteristic colonial form described by him. *R. compacta*, which was described inadequately from poorly preserved material, is not at present regarded as a valid species, but when a description of the new material has been prepared it is intended to re-instate it. *R. compacta* was first found off the coast of Northern Ireland in 1880. Since then it has been recorded once only, off Finistère. All the colonies from Stoke Point were found adhering to the concave sides of dead lamellibranch shells (mainly *Glycimeris glycimeris*) at a depth of 75–80 ft. They occurred on more than 60 per cent of the shells in one dredge haul and have also been obtained by diving.

The life cycle of *Rhabdopleura* is poorly understood. Recent authors agree with Schepotieff[4] that *Rhabdopleura* is dioecious. Observations on the material from Stoke Point have already revealed some points of importance. A number of female, but no male zooids have been found. They can be recognized by the presence of large ovoid eggs in the metacoel. It appears that these eggs may be released proximally, through a temporary opening at the posterior end of the metasome, to develop in the tube of the parent in much the same way as in *Cephalodiscus*. If this is so, the gonoduct seems to have no function except as a possible point of entry for spermatozoa. Fertilization in *Rhabdopleura* may therefore prove to be internal. After liberation into the tube the embryos develop and acquire a coating of cilia. They then probably crawl from the tube by squeezing past the zooid to begin their free life, presumably as larvae[5], although this stage has never been described.

Previous authors[4,6] have noted the rarity of sexual zooids and the disproportionate ratios of each sex. Vaney and Conte[6] believed *R. normani* to be a protogynous hermaphrodite, because they found a male with what they thought to be an ovary at the base of its stalk, but subsequently[4] this interpretation was considered to be erroneous, leaving their observations unexplained. Structures similar to those figured by them as an ovary (Pl. 8, Figs. 32, 36 and 42) have been found in *R. compacta*. It appears that the base of the contractile stalk may bud off gemmae which develop in the tube of the parent in the same way as the sexually produced embryos. A figure which Lankester[7] could not interpret (his Pl. 39, Fig. 2) provides corroborative evidence for this hypothesis. It shows part of the creeping tube of a zooid in which there are six embryos. One is attached to the contractile stalk, and appears to be budding from it. The colonies of *Rhabdopleura* may thus multiply asexually, as well as enlarging in this way.

It is hoped to develop these studies on *Rhabdopleura*. I wish to thank Drs E. and A. Southward and the Director of the Marine Biological Association's Laboratory for assistance, and also Professor E. W. Knight-Jones and Dr J. S. Ryland for helpful discussions. This work was supported by a Natural Environment Research Council research studentship.

β-Glycerophosphatase and Lateral Root Development

FOR many years plant anatomists[1] have believed that the emergence of lateral roots, which arise endogenously in the pericycle of the stele, occurs principally by mechanical rupture of the surrounding cortex. Torrey[2] expressed the view that emergence is probably assisted by hydrolytic enzymes, although to his knowledge there was no experimental evidence to support the postulate.

When investigating the distribution of β-glycerophosphatase in the roots of *Pisum sativum*, we found a large increase in activity of this enzyme in the region of lateral root development. Enzyme assays were carried out on 1 mm serial sections of 5 day old roots. The sections were ground into ice-cold buffer at *p*H 6·0 and an aliquot of the resultant homogenate was incubated with 10 mM Na β-glycerophosphate at 30° C. The rate of hydrolysis of the substrate was estimated by the rate of appearance of inorganic phosphate in the medium. Supplementary experiments had shown that no inhibitors or activators of the enzyme were present in the homogenates and that the rate of the reaction was proportional to the enzyme concentration.

The distribution of the enzyme activity along the axis of the root is shown in Fig. 1. There is a considerable increase in activity when expressed on a per section or per unit protein basis, in the region 2·5 cm to 4·0 cm from the root apex. This corresponds exactly with the region in which we observed lateral roots to be initiated. The results of Popham[3] show similarly that in 5 day old peas lateral roots were initiated from 2·3 cm behind the apex. This enzyme, in animal cells at least, seems to be associated with cell hydrolysis[4], so we thought the site of activity might be the cortex cells surrounding the lateral initials. To investigate this further, we carried out a histochemical examination of the localization of the enzyme. Cryostat sections were cut through the zone of lateral root development using the technique of Gahan *et al.*[5]. These sections were then incubated in the Gomori acid phosphatase reaction mixture[6] using 10 mM Na β-glycerophosphate buffered at *p*H 5·4. β-glycerophosphatase was localized as a brown–black precipitate of lead sulphide.

Examination of sections passing through the laterals showed activity clearly limited to the stelar cells and those cells of the cortex adjoining lateral roots (Fig. 2). Control sections to which either inhibitors or no substrate had been added showed no such activity. McGregor and Street[7] observed similar activity in the region of lateral root initials in tomato roots but they did not comment on its significance. Examination of sections under high power leaves no doubt that the activity surrounding the lateral occurs in the bordering cortex cells rather than in the outer cells of the lateral root itself (Fig. 3). The absence of activity around very young initials is a good indication that the β-glycerophosphatase activity is induced by wounding of the cortex cells, as a result of mechanical pressure exerted by the lengthening lateral initial. High glycerophosphatase activity has also been observed in the surface layers of roots where radial expansion is occurring, a situation where similar wounding is expected.

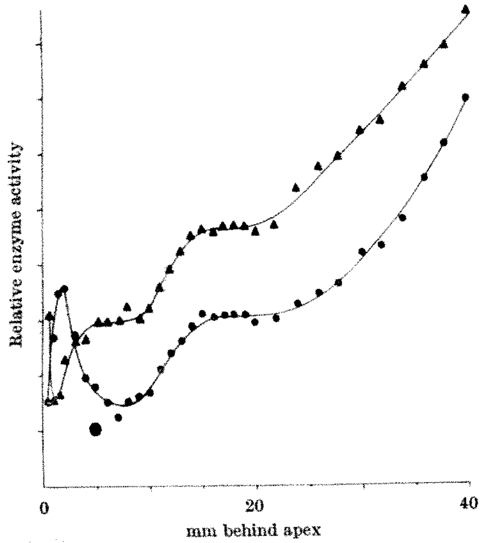

Fig. 1. β-Glycerophosphatase activity along the longitudinal axis of pea roots. Activity is expressed on a per section (●) and as a per unit protein (▲) basis.

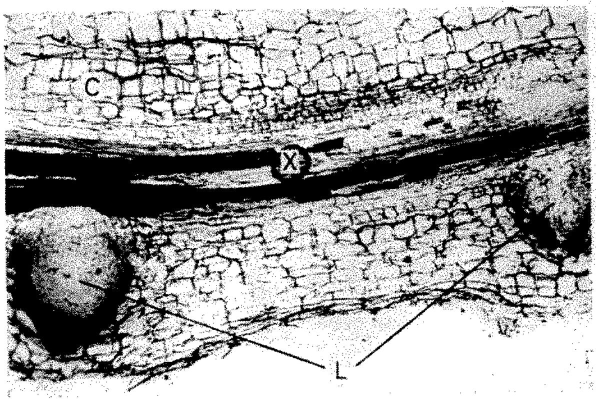

Fig. 2. Longitudinal section of a pea root through the region of lateral root formation. Incubated for 15 min, 30° C, in Gomori acid phosphatase medium. L, Lateral root initial; C, cortex; X, xylem cells. (× 40.)

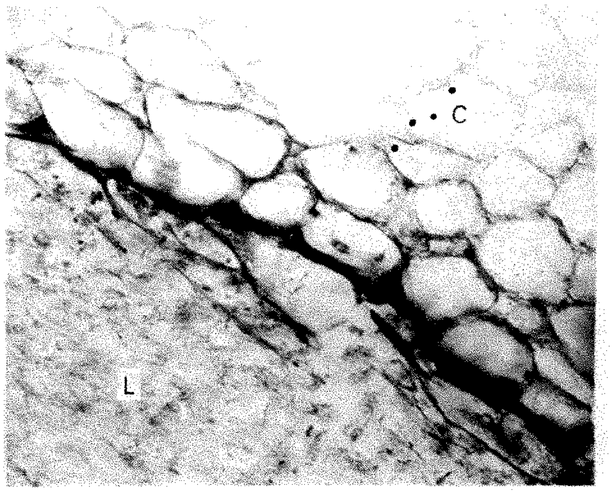

Fig. 3. Transverse section through the junction of a lateral initial and the cortex after incubating as in Fig. 2. L, Lateral root initial; C, cortex. (× 400.)

Our conclusion is that β-glycerophosphatase and perhaps other hydrolytic enzymes are induced by mechanical stimulation of cells surrounding the emerging lateral roots, and that this activity assists the lateral root in penetrating through the cortex.

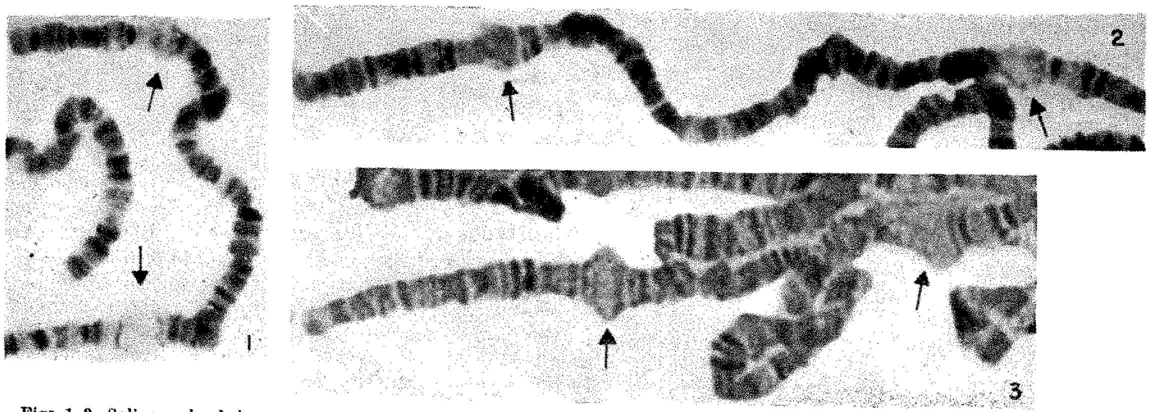
CYTOLOGY

Inhibition of Development in *Drosophila* by Cortisone

GENE transcription, whereby enzyme reactions mediate the synthesis of RNA molecules from DNA templates, has been investigated mostly in microbial organisms, but studies with higher organisms have made fundamental contributions to our knowledge of this process. One of the more rewarding areas of study has centred on the role of hormones in the regulation of transcription. Investigations in vertebrates have revealed that RNA synthesis can be stimulated in some cases[1,2], and inhibited in others[3,4]. There have been analogous findings on the regulatory effects of hormones in invertebrates. The phenomenon of puff formation in the polytene chromosomes of certain Diptera[5] has been extensively investigated. Autoradiographic techniques have established unequivocally a direct relation between puff formation and RNA synthesis, and these studies have long been accepted as cytological evidence of gene transcription[6].

Recent observations in *Sciara*[7] have indicated that the steroid hormone, cortisone, can completely suppress the puffing process and the uptake of tritiated uridine by salivary gland chromosomes, while the normal developmental sequence, viability and fertility are unaffected. RNA production is undoubtedly necessary for normal development and normal development can apparently occur in the absence of puffing, implying that puffing and uptake of tritiated uridine are not accurate reflexions of RNA synthesis in the cell. Because of the importance of this process in studies of gene activity in *Drosophila*, it seemed necessary to confirm the findings in this organism.



Figs. 1–3. Salivary gland chromosome preparations from late third instar larvae showing large puffs at the distal end of chromosome 3L. 1, Cortisone-fed larva, 2 mg/ml. 2, Cortisone-fed larva, 2 mg/ml. 3, Control larva.

Three preliminary experiments are outlined. In the first experiment, designed to test the effects of cortisone on developmental time and viability, eggs were collected and placed on a medium of agar, sucrose, dried yeast and propionic acid in 10 per cent ethanol (to aid in cortisone solubilization). To this medium was added 0, 1·0, 2·0, 5·0 or 10·0 mg/ml. of cortisone (Sigma). Concentrations greater than 10 mg/ml. were lethal. The time of emergence and the relative viability were determined for each group. The distributions of control versus experimental groups were compared by means of the Kolmogorov–Smirnov test. Table 1 shows the mean time of emergence, the *P* value for each distribution and the percentage relative viability. In addition to reducing the viability of the experimental groups, it can be seen that cortisone, administered in doses of 2·0, 5·0 or 10·0 mg/ml., causes a delay in the developmental sequence.

Table 1. EMERGENCE AND VIABILITY OF LARVAE FROM EGGS PLACED ON MEDIUM CONTAINING CORTISONE

Concentration of cortisone (mg/ml.)	No. of eggs	Mean time of emergence (h)	Kolmogorov–Smirnov *P* value	Percentage viability
Control	60	279·6		83·3
1	60	274·8	⩾0·20	61·6
2	60	298·6	<0·01	63·3
5	60	292·7	<0·01	71·7
10	60	292·7	<0·01	68·3

In the second experiment, eggs were deposited on a medium containing cortisone (0·5, 1·0, 1·5, 2·0 and 2·5 mg/ml.) and allowed to develop to the prepupal stage. At this time their salivary gland chromosomes were examined, the presence of large puffs such as *74EF–75B* and *78D* being used as criteria of gene activity. At each concentration of cortisone employed, large puffs were in evidence (Figs. 1–3). Concentrations greater than 5 mg/ml. resulted in the death of the larvae or the production of prepupae with salivary glands unsuitable for cytological examination.

In the third experiment, eggs were placed on cortisone-free medium and allowed to develop to the late larval stage. Salivary glands were removed and one of each pair was incubated in a cortisone solution (0·0025, 0·025, 0·25, 0·5 and 1·0 mg/ml. of 10 per cent ethanol–Ringer's solution) while the other was incubated in a control of 10 per cent ethanol–Ringer's solution for periods of 15, 30, 45, 60, 90, 120 and 180 min. At each concentration for each time period, large puffs, similar to those shown in Figs. 1–3, were observed in both the treated and control glands. There were several where the large, easily identified puffs were not evident in either treated or control glands. No correlation existed between these and the concentration of cortisone or incubation time, so they can probably be explained by the unavoidable variability in the developmental status of the various larvae.

Although it may be argued that measurement of the uptake of tritiated uridine could provide a more accurate assessment of the effects of cortisone on RNA synthesis, present cytological observations clearly indicate that cortisone does not visibly suppress puff formation. The possibility still exists that cortisone may act to delay development by slightly inhibiting general RNA synthesis or by inhibiting the synthesis of specific RNA species.

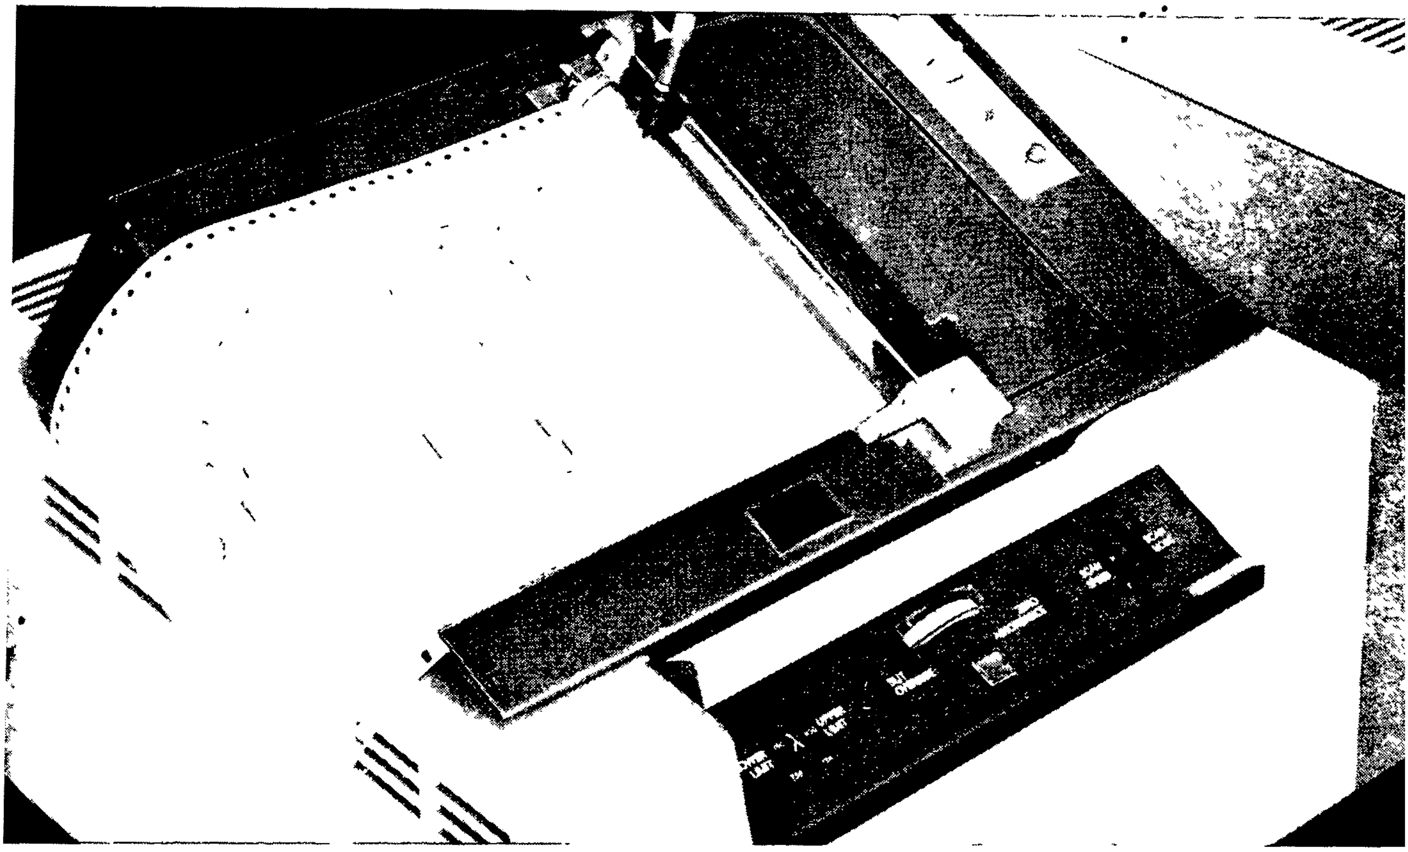
Set these controls on Perkin-Elmer's new U.V. Spectrophotometer and scan any wavelength range between 190—850 nm



Perkin-Elmer's new Model 402 Ultraviolet and Visible Spectrophotometer has a unique wavelength control system By setting upper and lower limit stops, you can scan any wavelength range singly or repetitively and present the spectra sequentially or superimposed.

You can scan the full range from 190 to 850 nm on a single chart in 2, 10 or 40 minutes.

You can expand the linear absorbance scale five times so that 0.3 absorbance units fills the chart.

You can perform kinetic studies at a fixed wavelength.

You can insert a new roll of paper into the flow chart recorder in 30 seconds and record 40 full range spectra without changing it.

You can choose from a wide range of accessories including a thermostatted multiple sampling unit - ideal for enzyme reaction studies

You can get faster, more accurate results over a larger range of applications with this highly automated instrument

You can get details immediately from Perkin-Elmer Ltd. Beaconsfield, Bucks. Telephone. Beaconsfield 2571, Telex: 83257 or Manchester Central 2569.

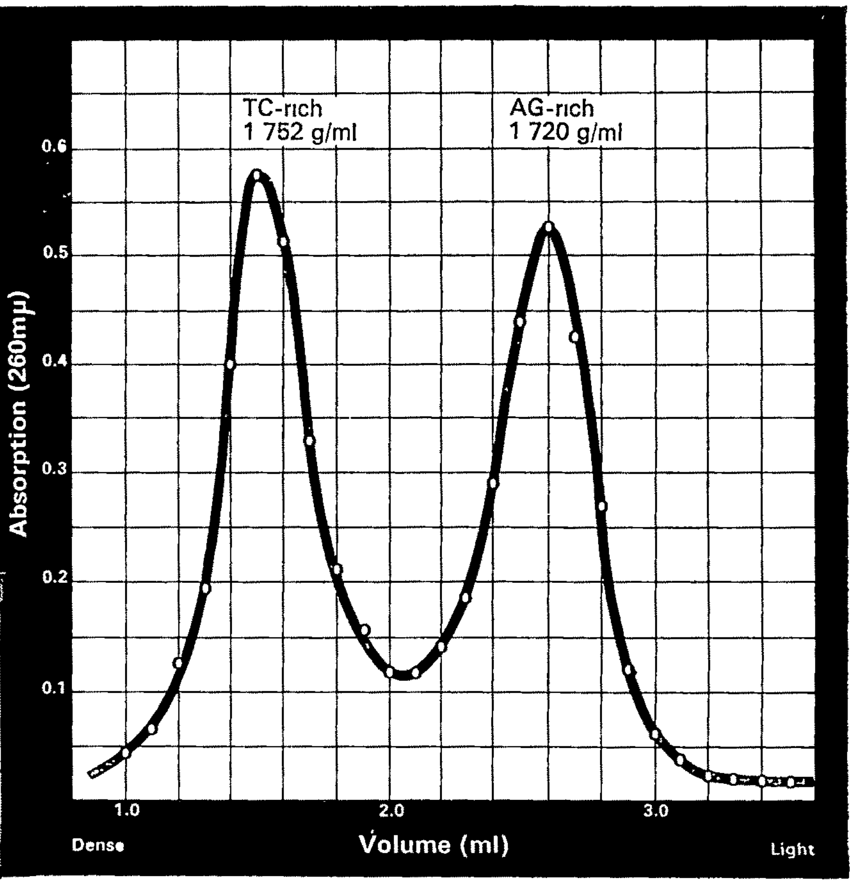
PERKIN-ELMER

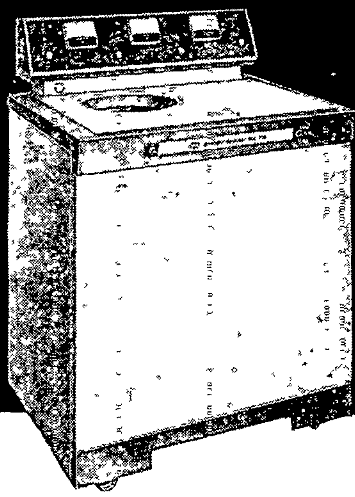
We have always stressed (among other things) the precise temperature control and exceptional rotor stability throughout the speed range of ***MSE SUPER SPEED PREPARATIVE ULTRACENTRIFUGES***

For instance, they made this possible:—

'FIRST TIME EVER'

Separation of the complementary strands of mouse satellite DNA using an Angle Rotor:-





50 μg of mouse satellite DNA in Tris-HCl buffer was treated with sodium lauryl sulphate at pH 12.7 and centrifuged in a caesium chloride gradient (initial density 1.765 g/ml at 25°C) for 20hr at 42,000 r.p.m. at 25°C.

This separation was carried out on an MSE Super Speed 50 Preparative Ultracentrifuge using the 10 x 10ml angle rotor instead of the more usual swing-out rotor. Full details of the procedure are given in MSE Application Sheet No 2, available on request.

Precise automatic control facilities, outstanding stability of temperature and an automatic oil recirculation system make MSE Super Speed Centrifuges ideal for the lengthiest and most exacting density gradient runs—in addition to their other applications.

APPLIED SCIENCE

Sintering in Gas Discharges

The application of gas-phase glow discharges to the activation of many chemical reactions is becoming increasingly important but the parallel application to various aspects of the processing of materials is not as yet so well known Dugdale[1] has described the mechanism and characteristics of the d c glow discharge and particular applications to both hollow cathode and hollow anode glow discharge heaters, which can be used for processes requiring an intense heat flux such as zone refining and evaporation machining

We have applied a microwave-stimulated electrodeless gas discharge to the sintering of various ceramics, metals, metalloids and mixtures and compounds thereof Particular consideration has been given to refractory oxides including alumina, beryllia, hafnia, magnesia and thoria and some results which are unusual in comparison with those achieved by conventional heating methods have been obtained This communication is principally concerned with the rate of sintering of alumina

Radio frequency power at 2,450 MHz is generated by a magnetron and fed to a rectangular wave guide by co-axial line The sintering chamber within which the discharge is established is a silica or alumina tube inserted transversely through the wave guide, which can be tuned so that the electric field intensity is a maximum in the zone in which the tube lies (Fig 1) At a fixed pressure in the sintering tube, the specimen temperature is controlled by varying the d c voltage applied to the magnetron

Thermocouples cannot be used to measure the temperature of the specimens because of direct heating by the glow discharge of the metallic elements of the couple Optical and radiation methods are also limited to some extent by interference from the radiation from the discharge below about 1,500° C true temperature, and it is then necessary to take measurements during short periods when the excitation is switched off Because of the low emissivity of the surfaces of oxide compacts and the "cold wall" conditions in the glow discharge, the apparent temperature is considerably below the true temperature Correction curves have been established by "push-out" experiments of pressed compacts of each oxide from a calibration furnace measured by reference thermocouple to a simulated "cold wall" environment where the apparent temperature is measured by successive approximations using optical and quick-reading radiation pyrometers

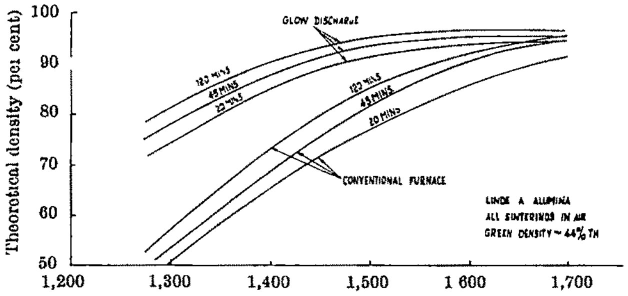

Fig 2 Isochronal densification curves for alumina

The pressure in the sintering tube is maintained at a chosen level in the range 1–50 torr by manipulation of a throttled backing pump and a controlled leak through which the required sintering atmosphere is admitted The nature of the atmosphere affects the maximum temperature which can be obtained Thus in hydrogen the peak temperatures are much lower (for example, 1,500° C) than in nitrogen, oxygen, air and carbon dioxide (about 2,000° C) for the same power input (1 kW) and experimental conditions A subsidiary consequence of change of operating pressure is the effect on the volume of the glow discharge For sintering small cylindrical pellets statically, or for the continuous sintering of long rods and wires, the discharge is usually constricted well inside the wave guide to give a short high temperature zone For the static sintering of long specimens, the discharge may be extended to envelop a length of more than 3 in The characteristics of the densification curves are such that very uniform sintering occurs over the full length of such a specimen

The densification achieved in pressed compacts of Linde *A* alumina by sintering for various time and temperature conditions in both glow discharge and conventional furnaces is plotted isochronally in Fig 2 as the percentage of theoretical density versus true sintering temperature The data illustrate the very marked increase in rate of densification in the discharge method It has been confirmed that the low pressure used in this method has not significantly affected the experimental results

The mechanical strengths of materials sintered in both ways are plotted in Fig 3 To obtain these results, small rods were isostatically pressed and sintered, and then machined to a square bar of a standard size used in these laboratories for four point bend tests While the average strength of the gas discharge sintered specimens does pass

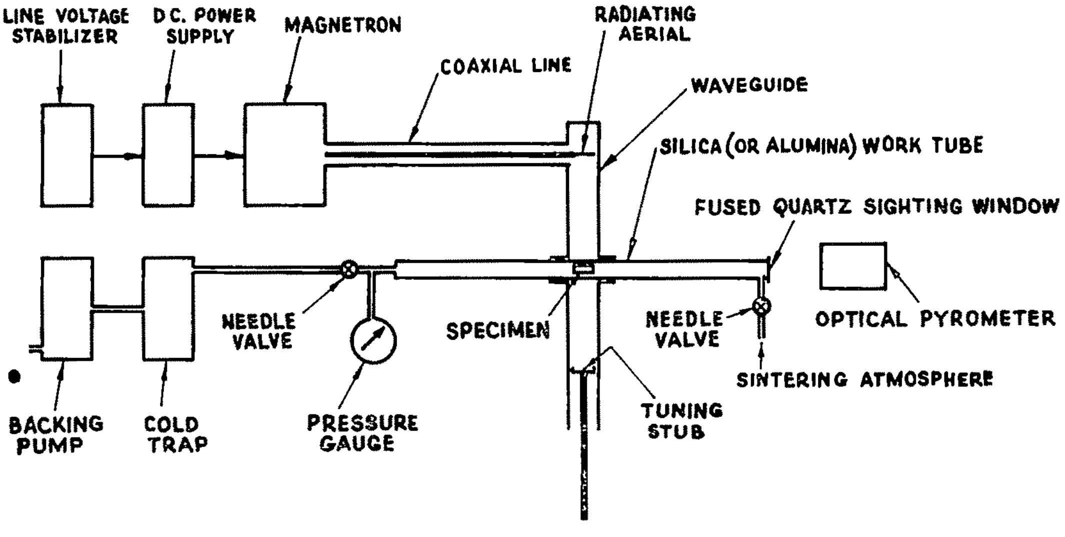

Fig 1 Gas discharge sintering apparatus

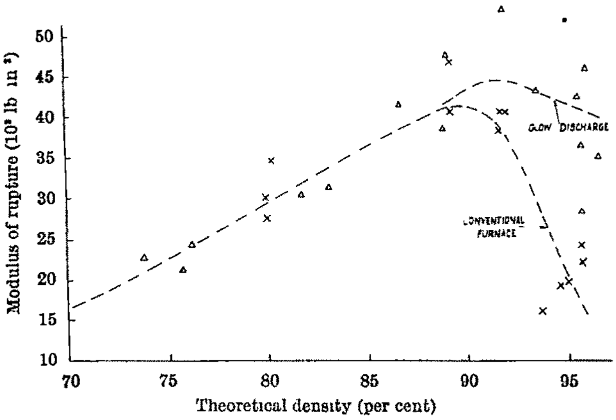

Fig 3 Strength-density relations for conventionally sintered and glow-discharge sintered alumina bars ×, Conventional furnace, Δ, glow discharge

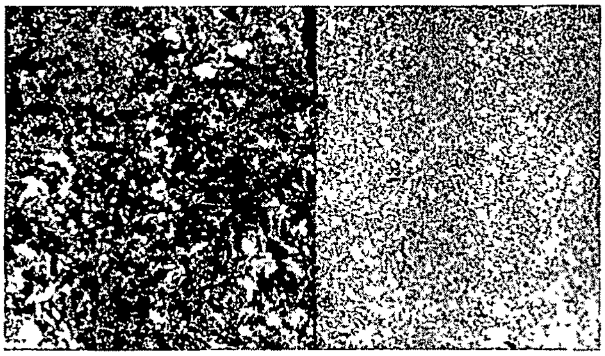

Fig 4 Fracture surfaces of coarse-grained conventionally sintered and fine-grained glow-discharge sintered bars (×16) (100 Å of aluminium vacuum deposited to increase reflectivity)

through a maximum and fall off slightly as high densities are reached, this effect is not nearly so marked as for conventionally sintered specimens of the same densities This difference in behaviour can be attributed at least in part to the much smaller grain size in discharge-sintered specimens (Fig 4) There is also the possibility that cleaner grain boundaries with fewer mechanical imperfections may contribute to the higher strength

The nature of the atmosphere is not a factor in obtaining the results given in Fig 2, for all specimens sintered at a chosen temperature in any atmosphere, the densities fall very close to the curve given, and the atmosphere influences only the efficiency of heating Chemical effects from this source can thus be discounted

While the experimental results given here are confined to Linde *A* alumina, the material which has been investigated most extensively, acceleration of densification has also been observed for aluminas from other sources and for other oxides The increase in rate of sintering is more marked with very fine highly sinterable powders like Linde *A* and Alcoa *XA*16 aluminas, and *NGK-CF* grade beryllia Even a moderately coarse oxide by these standards—Wah Chang Reactor Grade *S* hafnia, of nominal size 8μ as measured turbidimetrically—sintered to 90 3 per cent theoretical density in 25 min at 1,525°–1,550° C in an air glow discharge, however, whereas similar specimens treated in a normal furnace required a temperature of 1,700° C to reach 87 5 per cent density in the same time

The following hypotheses have been advanced to explain the observed rapid densification (1) an increased driving force through the increase in available surface energy associated with the cleaning of particle surfaces throughout the compact by release of adsorbed gases and precursor residues by ionic bombardment, (2) an increase in diffusion rate by the creation of vacancies and other mechanical phenomena caused by ionic bombardment, and (3) an increase in diffusion rate through local increases in temperature inside the pores of the compact The phenomenon of enhanced densification in gas discharge sintering is dependent on particle size and so it seems certain that the glow discharge is created within the pores; this is, of course, necessary for all three hypotheses. Kinetic and other relevant phenomenological studies are in progress

We thank Dr F K McTaggart, who developed the glow discharge device for use on the stimulation of chemical reactions, for many helpful consultations and Mr D P James for his contribution in the initial stages of the investigation

GENERAL

Improved Holographic Model of Temporal Recall

The static model of temporal recall which I recently proposed[1] as an alternative to Longuet-Higgins' model[2] is unsatisfactory in one respect From a fragment which is remembered it can recall earlier parts of the whole sequence This is unlike human memory which can readily recall later parts, but earlier parts only with great difficulty, if at all, especially if the sequence has been memorized by rote If we want to imitate human memory with models, we must take account of the weaknesses of the nervous system as well as of its powers Longuet-Higgins' model possesses this property, and so does the modified static system described here.

The original sequence is $A(t)$, $0<t<T$ We make a record of this in the form

$$\varphi(t_1) = \int_{t_1}^{T} A(\tau)A(\tau-t_1)\mathrm{d}\tau$$

This can be done only when the sequence has come to an end We can assume that first a straight "phonographic" record is made in the transient, short-time memory, and afterwards it is transcribed in a permanent memory in the form of the truncated autocorrelogram

We remember a fragment A' of A, which starts at t_0, so that

$$A'(t) = A(t+t_0)$$

up to some upper limit of t With this we form the recall function

$$R(t) = \int_{0}^{t} A'(t-t_1)\varphi(t_1)\mathrm{d}t_1$$

which is a truncated convolution of A' and φ. Substituting $\varphi(t_1)$, we obtain an integral of the triple product

$$A(\tau)A(\tau-t_1)A'(t-t_1)$$

over the trapezoidal area $t_1<\tau<T$, $0<t_1<t$, illustrated in Fig 1 For comparison the trapezoid used in the previous model is also shown

It is readily seen that if the sequence A is "noiselike" the correlation A', A will have a sharp maximum at $\tau=t+t_0$ and this will single out the value of $A(\tau)$ at this abscissa, so that apart from some noise

$$R(t) \propto A(t+t_0)$$

Thus we can recall the whole sequence A, but only from t_0 to T, and thereby the model imitates the weakness of a

person who has memorized something by rote. My previous model, starting with a fragment which begins at t_0, could recall the sequence from $t=0$ to $T-t_0$ There was nothing to prevent it, after having obtained the beginning of the sequence, from starting again and recalling the whole This may be a better method if we want to construct a library for fragmentary recall, but it is rather "inhuman"

There is still a feature which distinguishes this model from Longuet-Higgins' bank of resonators It contains nothing which prevents reading the reconstructed sentence backwards, which is a difficult feat for the human memory It shares this feature with all static stores, such as a gramophone record or a tape recording, unless a "ratchet" is added which allows only one sense of reading Longuet-Higgins' bank of resonators contains such a ratchet, because it is a dynamic model

Impotence Principle in Descriptive Morphology

It was recently proposed[1] that biological form should be specified by an expansion of the characteristic function of the form as a weighted sum of the elements of a complete set of orthonormal functions The method was applied to two-dimensional forms, using Walsh functions[2] In the discussion it was suggested that each weight might be maximized with respect to all possible transformations of the form caused by any combination of displacements, rotations and uniform contractions or expansions It was conjectured that this sequence of "maximal" weights constituted an unequivocal specification of the form, that is to say, two different forms would always be represented by different sequences In the case of the Walsh functions, these weights would be real numbers lying in the interval $-\frac{1}{2}$ to $+\frac{1}{2}$, except for the first one which would lie in the interval 0 to 1

If one accepts the notion of form in complete generality, this conjecture is false We have not been able to construct an actual non-trivial counter-example in the case of two-dimensional forms in a square frame that we had discussed[1]; but we have found one for a similar system using a fixed circular frame, in which the form is blown up or contracted so as to just fit into the frame and only rotational transformations need to be considered This counter-example led us to think that there may be some inherent limitation on the possibilities of mathematical description in morphology, and this is indeed the case We prove that it is impossible uniquely to specify all three-dimensional or two-dimensional forms by finite or denumerable sequences of real numbers.

We prove this for two-dimensional forms—it will then hold for three-dimensional forms, because all two-dimensional forms can obviously be put in one-to-one correspondence with a subset of all three-dimensional forms

For definiteness, consider a Cartesian co-ordinate system in the plane and let $f(x,y)$ be the characteristic function representing one specimen of a form, that is, it takes the value 1 at points covered by the specimen and 0 elsewhere.

Let $f\alpha(x,y)$ be the characteristic function representing any other specimen of this form, that is, the original form transformed by any combination of displacements, rotations and finite uniform contractions or expansions

Let $S_f = \{f\alpha(x,y)\}$ be the set of all such transformed functions derived from $f(x,y)$ The cardinality of S_f is clearly c, the cardinal number of the continuum

The cardinality of the set of all characteristic functions $f(x,y)$ whatever is obviously 2^c Because the S_fs constitute a partition of the set of all these characteristic functions into disjoint subsets, it follows that if k is the cardinal number of the set of S_fs, then

$$k \times c = 2^c \qquad (1)$$

k is clearly the cardinal number of all possible two-dimensional forms, each S_f corresponding uniquely to a single form

Suppose it were possible to assign to each S_f a finite or denumerable sequence of real numbers, expressed for example in binary digits To each such sequence we can make to correspond in one-to-one fashion a single real number, for example, if d_{ij} is the jth digit of the ith real number in the sequence one could form the real number $d_{11}\, d_{12}\, d_{21}\, d_{13}\, d_{22}\, d_{31}$ and so on, where in the obvious systematic way one writes down successively the digits, the sum of whose index numbers is respectively 2, 3, 4, . . , and so on. Hence one would have been able to set up a one-to-one matching correspondence between the S_fs and the real numbers or a subset of them One must therefore have

$$k \leq c \qquad (2)$$

From (1) and (2) it would follow that

$$2^c \leq c \times c$$

But

$$c \times c = c$$

Hence

$$2^c \leq c, \text{ which is impossible}$$

Thus we see that there just are not enough real numbers for the unique specification of all possible forms

This result does not mean that one should give up the numerical approach to morphological description. For, it depends on interpreting form in its fullest possible generality—for example, a leaf with an infinite number of smaller and smaller holes would under this rubric be a form Clearly, natural forms would constitute some subset of all forms, and it would be profitable to look for some general model for characterizing them. For such a restricted set of forms it may well turn out that real numbers or perhaps even rational numbers would be sufficient for unequivocal description One possibility, suggested by Professor J. A Robinson, is—in the two-dimensional case, for example—to consider only forms whose boundary can be approximated to any desired degree of accuracy by a finite number of polygons, other possibilities readily spring to mind

Incongruent Surfaces in the Human Hip Joint

Hammond and Charnley[1] have recently given support to the view that the femoral head is almost exactly spherical, that the surfaces of the acetabulum and femoral head are congruent so that "very perfect contact of all parts of the cartilaginous surfaces is to be expected in any position of the hip joint" In the past, however, several observers[2,3] were convinced that the surfaces of this joint are incongruent or, at best, fit one another in only one position If the latter view is correct, contact will not be made over the entire joint and the site and size of the actual contact areas in a given joint will depend on the relative position of the joint surfaces and on the magnitude and direction of the load transmitted through it

Goodfellow and Bullough[4] have shown that the surfaces of the human humero-ulnar joint are incongruent in youth but that, in old age, the surfaces become more closely fitting, they have further suggested[5] that the same effects exist in the hip joint Changes in joint profile with age were observed by Ogston in 1878 (ref 6) but he did not comment on the congruence of the surfaces

We have measured the curvature of both surfaces of the hip joint A three-legged gauge was used, the central leg was driven by a micrometer screw, and the outer legs had a span of 0.75 in Fifty-three hips, obtained at necropsy from subjects of different ages, were examined The radius of curvature was measured at four points, equidistant from each other along an equatorial circle, on each surface, taking four measurements at each point

It was found that there were substantial differences in curvature from point to point on both the acetabulum and the femoral head The difference between the maximum and the minimum radius, divided by the average of the four radii, was taken to be a measure of the departure from sphericity of each surface Fig 1 shows this ratio plotted against age for each of the 106 surfaces examined

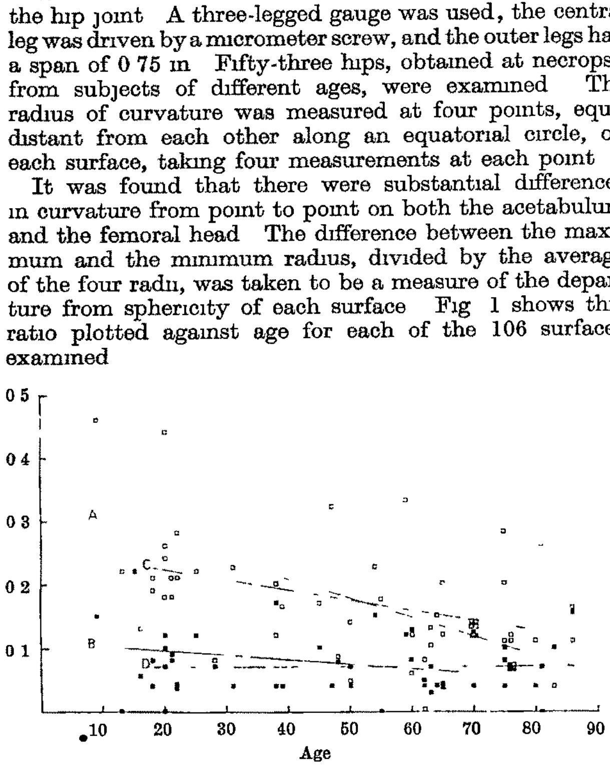

Fig 1 Departure from sphericity with age of the femoral head (■) and acetabulum (□) $y = R_{\max} - R_{\min}/R_{\mathrm{av}}$

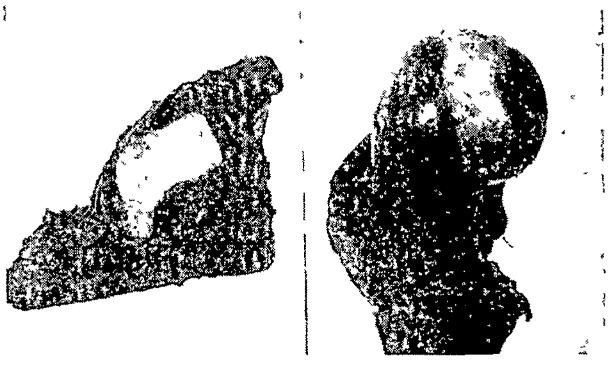

Fig 2 Disarticulated hip from a young male The non contact areas in 10 degrees of flexion are dyed

A statistical analysis was carried out on these data, fitting "least square" straight lines to the data for the acetabulum and for the femoral head These calculations were made including and excluding the data for hips aged eighteen years and younger The equations of these lines are (with 95 per cent confidence limits)

A, Acetabulum $y_0 = -0.003\,X_0 + 0.327 \pm 0.221$ (more than 9 yr)

B, Femoral head $y_0 = -0.0005\,X_0 + 0.105 \pm 0.103$ (more than 9 yr)

C, Acetabulum $y_0 = -0.0016 + 0.2526 \pm 0.135$ (more than 18 yr, that is excluding growth period)

D, Femoral head $y_0 =$ horizontal (more than 18 yr, that is excluding growth period)

Despite the scatter in these data, some conclusions can be drawn Neither the acetabulum nor the femoral head is spherical, the acetabulum is less spherical than the femoral head, and there is a "highly significant" decrease in the asphericity of the acetabulum with increasing age (correlation coefficients -0.399 for line *A*, -0.362 for line *C*) It is worth noting that nine of the ten specimens examined by Hammond and Charnley came from subjects aged 60 or more

The joint surfaces are not spherical, and so they cannot be congruent, although these data do not necessarily deny the proposition that the surfaces may be more congruent in some positions than in others

Because the hip joint is incongruent we would suggest that the site and size of the actual contact areas will depend on the position of the joint and the magnitude and direction of the applied load We have built a loading frame to apply static loads of known magnitude and direction to a hip joint in a variety of positions in simulated body conditions. The contact areas can be detected by adding dye to a bath of Ringer solution in which the loaded hip is immersed The results of a preliminary test, made on a young male hip in ten degrees of flexion, hre shown in Fig 2 The white areas on both the femoral aead and the acetabulum are taken to be the zones of contact which clearly do not cover the entire available surface

BOOK REVIEWS

CANCER CHEMOTHERAPY

Immunity, Cancer, and Chemotherapy

Basic Relationships on the Cellular Level. Edited by Enrico Mihich. Pp. xxiii + 390. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1967.) 144s.

WITH as yet very few exceptions, drugs used in the treatment of malignant disease are effective because they have the capacity to kill dividing cells in general and their action is not restricted to cancer cells. Cell division forms an essential part in the genesis of the immune response, and so it is not surprising that many anti-cancer agents interfere both with the formation of antibody and the rejection of foreign tissues. This dual action poses some extremely serious problems for cancer chemotherapy, for many tumours in experimental animals are now known to contain antigens in their membranes that are not present in the normal cells of the animals. These antigens introduce a slight degree of "foreignness" and in many experimental situations the growth of primary tumours is slowed down by an immunologically mediated host reaction. The possibility exists, therefore, that the immuno-suppressive action of anti-cancer drugs may impair the anti-tumour host response, and this has been observed with grafted tumours where the drugs reduced the magnitude of a primary immune reaction. No information appears to be available for primary tumours where an immuno-suppressive action would have to be directed against an already established immune response.

In man, the situation is still more complex, because the techniques used in animals to detect the presence of an anti-tumour host reaction cannot be applied clinically and the therapist does not know whether such a response exists in a particular patient. The theoretical danger of immuno-suppression is clearly not an argument against cytotoxic drugs when there is extensive disseminated disease but there are other circumstances such as prophylactic administration post-operatively when their use may be questioned.

A thorough discussion of the available knowledge of the influence of immuno-suppression on chemotherapy would clearly be most valuable but the book under review does not meet this requirement. It is the report of a symposium that took place in Buffalo, New York, but there is no indication as to when the meeting was actually held and none of the papers reproduced is, in fact, very topical. In some respects the most interesting part of this volume is the report of the discussion, which is both stimulating and informative, and the editor deserves great credit for what must have been a time-consuming and difficult task.

The title is misleading, for only one of the eighteen papers deals specifically with cancer and there are three papers by Sterzl, Schwartz and Berenbaum respectively devoted to the mode of action of immuno-suppressive agents without, however, going into their anti-tumour properties. Three-quarters of the book is concerned with different facets of immunology and includes such problems as the nature of the cellular response to antigens, the processing and localization of antigens, as well as the biochemical mechanism of protein synthesis. This vast field is covered too thinly for this book to make a worthwhile contribution to the scientific literature.

PETER ALEXANDER

IMMUNOLOGICAL VADE-MECUM

Handbook of Experimental Immunology

Edited by D. M. Weir. Pp. xiv + 1245. (Oxford and Edinburgh: Blackwell Scientific Publications, 1967.) 160s. net.

IMMUNOLOGY was derived from bacteriology, but has long since developed into a discipline in its own right which impinges upon, and is useful to, other disciplines such as biochemistry, medicine, genetics or parasitology and has a peculiar fascination for molecular biologists. In doing so it has developed its own jargon and its own techniques. Although these may appear frightening to persons unfamiliar with them, some of the techniques are astonishingly simple, others are complicated in concept, though technically easy (provided—and this is a big proviso—that suitable reagents are available), and others are just plain complicated. There is no corpus of accepted experimental techniques, although good monographs exist relating to some of them, and Kabat and Mayer's *Experimental Immunochemistry* (especially the first edition, which made less demands on its readers) has probably done more than any other single work to advance immunology in those fields which it covered. It has been agreed for quite a number of years that a comprehensive book which explained immunological techniques in sufficient practical detail to make them usable by non-immunologists as well as immunologists was highly desirable. The questions were who could be persuaded to write it, and how much or how little theory would be required to make the techniques more than plain cookery. The publication of a *Handbook of Experimental Immunology* has therefore been awaited with considerable eagerness.

It contains thirty-six chapters and two appendices, written by twenty-nine authors from Britain, ten from the United States and three from the mainland of Europe. All the authors have contributed to the practical aspects of the methods which they discuss, and some are their originators. This has ensured that the presentation is authoritative. On the whole a fair balance has been kept between the need to supply a theoretical background and the provision of sufficient technical detail to allow the user to put the methods described into practice without further resort to other books or journals. Since each chapter contains a bibliography (which is well selected so far as I could judge) it is usually possible to find a reference to some specialized technique such as the isolation of a specific anti-hapten antibody.

The handbook contains more than 1,200 pages, and covers methods for isolating and characterizing immunoglobulins, for study of their synthesis *in vitro*, and for examining human immunoglobulin allotypes. There are useful chapters on preparation of viral, tissue and bacterial antigens (but surprisingly omitting the pneumococcal antigens, which are well characterized chemically, even if now of lesser medical importance than before the introduction of antibiotics). Several chapters deal with different aspects of primary and secondary antigen–antibody interaction, including immunofluorescence and immunoferritin techniques, the use of radio-iodinated proteins, and methods for gel diffusion, micro-complement fixation and passive haemagglutination; specific applications in virology, mycology and parasitology, methods for study of anti-tissue antibodies and of various aspects of cell mediated immunity, especially in relation to transplantation, demonstration of antibody forming cells by localized haemolysis in gels, methods for studying reaginic antibodies and pharmacological mediators, and there are appendices on statistical methods and on the use of emulsions for immunization.

The choice of what to include or exclude is inevitably somewhat arbitrary and to satisfy everyone's needs in one volume is probably impossible. Most laboratories concerned with immunology are likely to find that the bulk of their methodology has been catered for, even if indirectly (for example, the commonly used method for quantitative assay of immunoglobulin concentrations by radial diffusion against monospecific antisera is mentioned only in the barest outline). A future edition, however, might benefit by consideration of chromium-51 labelling of red cells and leucocytes; mixed cell agglutination and mixed antiglobulin tests; radio-immuno assay of pharmacologically active peptides; cytophilic antibodies other than reagins, methods involving inhibition on stimulation of cell migration, and perhaps by an extension of the chapter on methods for isolation of specific antibodies. It would certainly benefit by a better index, for a good index enables the reader, who is unlikely to read from cover to cover, to make the fullest use of the wealth of information incorporated in the handbook. Furthermore, quite a brief use of the index revealed to me an uncomfortably large number of errors. These are minor criticisms. The book fulfils a real need and will not disappoint the expectations of the many who have awaited its publication. At 160*s* its price is very reasonable. J. H. HUMPHREY

PLANT PATHOLOGY

Physiological Plant Pathology

(Botanical Monographs, Vol. 6.) By R. K. S. Wood. Pp. xi+570. (Oxford and Edinburgh: Blackwell Scientific Publications, 1967.) 63*s* net.

UNLIKE animals, plants have few specialized organs and, with this generalized organization, the symptoms of plant disease are less specific and informative than the symptoms of animal disease. Symptoms only provide the most general expression of the relation between the host and the parasite. A deeper understanding of this relationship must be built up by integrating into a coherent whole the results of a variety of observations and experiments, which are usually open to various interpretations which can be highly subjective. Professor Wood tries to give an unbiased picture by presenting as complete an account as he can of the available evidence with suitable comment and leaving the reader to make his own judgments. The result is about 500 pages of comment supported by a bibliography of about 1,300 references ranging in time from 1866 to 1965. This approach leads to some curious anomalies in treatment since well founded and generally accepted concepts tend to generate less literature than those that are more controversial. For example, the role of gibberellins in the development of bakanae disease of rice or the relationship between protocatechuic acid and resistance to onion smudge are dismissed in four and one pages respectively, while the very doubtful part played by fusaric acid and lycomarasmin in fusarium wilt of tomatoes, which is far from accepted, is discussed for sixteen pages. The current state of knowledge and opinion relating to the effect of toxins in tomato wilt is admirably summarized in the first two paragraphs of the tenth chapter: this would have sufficed for the casual reader while the addition of a short introduction to the bibliography would have introduced readers, more deeply concerned, to the full controversy. If this approach had been applied to other sections of the book the reader would have a clearer picture of the development of the subject and the benefit of Professor Wood's long experience in the field in assessing the present position.

The book is of unquestionable value to specialists, and students wishing to find their way into almost any branch of the subject will find appropriate references and comments to launch them, whether for teaching or research. However, a shorter and more critical text introducing the references would have filled this need equally well and would also have provided the student with a better balanced and more readable account of the subject: one which, by thinning the trees, could reveal more of the wood. However, it is fair to say that except in the case of balance, which is, after all, a matter of personal opinion, the book fulfils the aim of the series to produce a "carefully balanced account which will inform the advanced student, assist the lecturer and be a point of departure for the specialist".

There are a few typographical errors, but only two were noted which were likely to cause confusion: in Figs. 9.3 and 9.4 the "N" of pyridine is shown as if substituted on a benzene ring. It is also a pity that the plates come adrift so easily when the book is used. All in all, *Physiological Plant Pathology* is a very useful book and at present day prices represents a good money's worth.

S. H. CROWDY

WHAT GOES ON IN CELLS

Progress in Nucleic Acid Research and Molecular Biology

Vol. 7. Edited by J. N. Davidson and Waldo E. Cohn. Pp. xv+467. (New York: Academic Press, Inc. (London), Ltd., 1967.) 140*s*.

MUCH progress in molecular biology has been achieved by putting a searchlight on a few types of micro-organisms. Although the concepts that have been developed in this way are of inestimable value for the study of higher organisms, we still understand very little about the structure and replication of the cytologist's chromosomes, the regulation of chromosomal activity, the stability of messenger RNA, or the precise form in which it passes to the sites of protein synthesis.

Five of the nine essays in this welcome volume are concerned with crucial problems of molecular-cum-cell biology in higher organisms. Gavosto gives a clear and concise account of autoradiographic studies of DNA replication in human chromosomes. He describes how various chromosomes differ both temporally and spatially in their patterns of DNA replication and discusses the interesting differences that have been found between the replication patterns of chromosomes from normal and leukaemic cells. Hnilica's essay on the nuclear proteins is a comprehensive review which will prove to be valuable both for the specialist and for advanced students. Chantrenne and his colleagues, Burny and Marbaix, have written a clear and critical account of the search for the messenger RNA (*m*RNA) of haemoglobin. Although the concept of *m*RNA is now firmly held, many important questions about its nature and stability have not been satisfactorily answered even in bacterial systems. Reticulocytes ought to be an ideal source of a specific *m*RNA from higher organisms, for these cells make only one protein. Unfortunately, despite almost ten years of intensive effort in several laboratories, a clear demonstration of the haemoglobin messenger has not been achieved. In the next article, Hadjiolov presents a wider discussion of the nature of *m*RNA in animal cells and the theme is extended further by Nemer in the next article—an excellent and readable survey of information transfer by RNA during embryogenesis. Will embryos provide the principal experimental system to unlock the secrets of *m*RNA in animal cells?

Among the other articles in the book, there is a long and thoughtful review of the genetic code by Woese, who includes the mechanism of its operation and its possible origin and evolution. Larsson and Reichard give a first class account of the enzyme reduction of ribonucleotides to deoxyribonucleotides. This key process is controlled by various ribo and deoxyribonucleotides in a complex manner for which Larsson and Reichard have been able to suggest an elegant model. Phillips and Brown survey the mechanism of action of hydroxylamine—one of the most specific chemical mutagens known and the only one to have been used confidently in codon assignment. Nevertheless, it is still difficult to decide which particular chemical reactions cause the mutations

Phillips and Brown lead us along the firmer evidence that is available and argue a convincing case for the mechanisms that they propose The final article, "Mammalian Nucleolytic Enzymes and their Localization", is by Shugar and Sierakowska and covers both the techniques that are used and the possible functions of nucleases

The articles emanate from seven countries and are all of high standard, even when measured against the merits of the earlier volumes of the series The editors and publishers are to be congratulated not only for the quality of their product but also for their apparent success in publishing it quickly and so making its contents available when they are still young enough to have their greatest impact. K BURTON

COASTAL DEVELOPMENT

Processes of Coastal Development

By V. P Zenkovitch Edited by J A Steers Translated by D G Fry. Pp xv+738 (Edinburgh and London Oliver and Boyd, Ltd , 1967) 252*s*

PROFESSOR ZENKOVITCH has long been known personally to western scientists working on problems of coastal evolution As a member of the Commission on Coastal Geomorphology of the International Geographical Union, he has visited many universities and research establishments outside Russia His own contributions in this field are thus widely known, despite problems of language This English edition of a book first published in 1962, however, may well surprise even professional coastal geomorphologists at the depth and breadth of coastal research in the Soviet Union It will certainly make available for the first time to a wider audience the work of a large number of Soviet scientists whose names are not known outside communist countries Similarly, it will present work on coasts which, until now, could only be regarded by most of the world's students of coastal problems as *terrae incognitae* in the geomorphological sense

Inevitably, comparisons will be made between this book and the classic *Shore Processes and Shoreline Developments* by D. W. Johnson, published almost fifty years earlier It is a current criticism of the Davisian approach, which Johnson applied to coasts, that process is neglected and too much emphasis is placed on "stage" Perhaps the reverse criticism may come to be applied to Zenkovitch in the sense that contemporary processes are emphasized at the expense of those which, however significant in coastal development, have ceased to operate. There is growing realization in Britain, for example, that much beach sediment may be of glacial origin winnowed by the waves of the transgressing Flandrian sea from sea floors now below the depths from which modern waves can move material shoreward Zenkovitch does not ignore fluctuations of sea level during the Quaternary, but he does not devote as much attention to their contribution to the form of modern coasts as some might wish

Perhaps the greatest contrast between Johnson and Zenkovitch lies in the Russian's insistence that coastal geomorphology is an experimental science rather than an exercise in observation and description In his view, theory must be based on experiments in the field rather than in wave tanks, in which theories can be validated but not conceived As an example of this approach, the large-scale field trials of the kind carried out with fluorescent tracers, at Anapa on the Black Sea coast, using aerial ropeways to allow for the continuation of work in storm conditions, are significant They have led to notable advances Zenkovitch's division of accumulation forms into those developing on coasts with saturated and unsaturated sediment flow, is a major result of quantitatively based studies His theoretical treatment of the development of sectors of deposition and erosion, where coastal trends change, will be widely studied and applied

Zenkovitch incorporates much of the results of work outside the Soviet Union in his interpretation of coastal processes and form Thus, for example, he revives Cornaglia's neutral line concept[1], relating to the development of shore profiles of equilibrium, which has largely been overlooked by contemporary western workers His ideas on surf base, as distinct from wave base, echo Dietz's criticisms of some of Johnson's approach[2]

Although much of Zenkovitch's work best known in the West has been sited in the Black Sea, the book includes studies by himself and others of all the seas of the Soviet Union The examples taken from Arctic coasts are of particular interest as being outside the experience of most non-Soviet students He can claim to have worked in tidal as well as in non-tidal environments, and in conditions dominated by ocean swell as well as in areas dominated by storm waves However, some of the major problems associated with the differences between these environments have not been sufficiently emphasized The chapter on tidal conditions is unsatisfying and the significant role of tidal streams on open coasts in inhibiting shoreward transport of sediment is largely overlooked Similarly, the views of Australian writers on the importance of sediment supplied from the nearshore zone, under the influence of ocean swell, in the development of spits and bars, are given little or no attention

These are, however, only differences of emphasis They do not detract significantly from the value of a book which is destined to be a required text for many years to come It sets a standard against which future work will be measured and establishes the Shore Division of the Institute of Oceanography in Moscow as one of the world's leading Coastal Studies Institutes In presenting this major treatise to the English-speaking world, the translator and the editors have, themselves, made notable contributions C KIDSON

UNSALEABLE KNOWLEDGE

Scienza e Tecnica 68

Annuario della Enciclopedia della Scienza e della Tecnica Pp viii+484 (Milano Arnoldo Mondadori Editore, 1967) Lire 14,000

THIS is a beautifully produced book for which it is hard to see any definitive use It is the first annual supplement to Mondadori's *Enciclopedia della Scienza e della Tecnica* and contains information of two kinds The first thirty pages are short articles written in newspaper form which describe events of major scientific interest, including the awarding of the Nobel Prizes, between October 1966 and October 1967 The remainder of the book is a series of forty-four essays "which has as its theme the great problems to-day being tackled by science and technology in order to satisfy our basic needs and to broaden the limits of our knowledge"

On the face of it, the volume has much to commend it The essays and articles, many by distinguished scientists, are well written and excellently illustrated Within the six sections of the book the selection of topics must inevitably be arbitrary and partial, but subject to this limitation the editors' choice is not, on the whole, to be quarrelled with In the first section, devoted to the transformation of the environment, Dr B R Sen, director general of the FAO, gives a useful synopsis of the world food problem concluding on the surprising note that "it is possible to hope for a definite improvement in the condition of the human race during the following decades". Professor B G Bogorov, of the University of Moscow gives an interesting account of the oceanic food chain, while Dr A Nyberg, director-general of the World Meteorological Service, expands on the possibilities of a universal weather service

The second section, on the adaptation of man to his environment, includes essays on contraception, hallucinogens, gerontology and reanimation, while the third section discusses nuclear reactors, real time computers in medicine and bionics The composition of the fourth section, which aspires to cover problems of research and development, may give some ground for surprise In reviewing the period in question many might include on their list of interesting advances topics from cosmology, oceanography, molecular biology, immunology and particle physics The editors have selected none of these topics, instead they have included in their limited space an interesting but not primarily important article on melanin, two articles on photochemistry and a discussion of the lattice energy of ionic crystals If the articles here selected are intended to represent the major themes of contemporary interest, the editors' judgment would seem to be seriously awry For which reason this is probably the least satisfactory section of the book, its best piece, which does not properly belong to it, is a discussion of the conservation of works of art and the restoration of those damaged in the Florence floods

The next section, devoted to the mathematics, logic and philosophy of science, is a praiseworthy attempt to cover a not particularly tractable subject But the value may well be questioned of including an essay on the theory of distributions which almost inevitably will lose the non-mathematical reader in its first few paragraphs The last section of the book, "The Politics of Scientific Research", discusses the science research policies of various countries, excluding the USSR, more by way of description than analysis, and without attempt at serious comparison The newspaper style articles which begin the book are perhaps an artificial but certainly successful means of conveying to the general reader some of the immediacy of science

In substance the book contains a wide variety of attractively presented information, is well planned except in its fourth section, and is excellently produced But although the publishers presumably know their business, it is hard to see for what class of reader the book is intended and by whom it will be bought Its price puts it beyond the shelves or coffee table of most individuals, and librarians may consider that it is not a work of reference, because it does not attempt to give an inclusive coverage of its chosen field The clarity of a publisher's intentions may always be questioned when it is left to the blurb writer, not to the editor in his preface, to state the purpose of a book, and such is the case with *Scienza e Tecnica 68* The volume will apparently be "useful both for the specialist who wants to find an authoritative account of current research in fields other than his own" as well as for the general reader In the English speaking world at least, this purpose is more topically and cheaply covered by the relevant scientific magazines, and even among readers of Italian the only buyers on impulse may be those who already possess the parent encyclopaedia, to which indeed the articles in the book are copiously referenced

N M L Wade

OBITUARIES

Professor E R Redfearn

Eric Reginald Redfearn, professor of biochemistry at the University of Leicester, died on March 6 in a road accident which also took the life of his elder son Redfearn's death, at the tragically early age of 43, ended a career in biochemical research which spanned only 16 years but sufficed to establish him as an internationally recognized authority on the mechanism of biological electron transport

Redfearn was educated at Wallasey Grammar School, which he left in 1943 to join the Royal Air Force Early work with airborne radar, and later service as a flight sergeant instructor in the education branch, confirmed him in his resolve to devote himself to science, and provided him with an understanding of electronics which was to stand him in good stead in his later work On demobilization in 1947 he spent a short period in industry before entering the University of Liverpool in 1948, he gained his B Sc with honours in biochemistry in 1952 Working under the supervision of Dr J Glover on the biogenesis of vitamin A and retinoic acid, Redfearn took his Ph D in 1954 and was appointed to a lectureship at The Queen's University, Belfast, where he continued and extended this work His return to a lectureship at Liverpool in 1957 coincided with the discovery, by Professor R A Morton and his colleagues, of coenzyme Q (ubiquinone) Redfearn's interest in this work was immediately aroused and he developed methods, which are still widely used, for the isolation and characterization of the oxidized and reduced forms of the various quinones His work was instrumental in establishing ubiquinone as a physiologically important electron carrier and in defining its site of action

In 1962, Redfearn was appointed to a senior lectureship in biochemistry at the University of Leicester Here his teaching experience and enthusiasm proved most valuable in developing the newly established department and in planning for the move and integration of that department into a separately housed school of biology In 1964, the University of Leicester conferred on Redfearn a personal professorship, in the same year the University of Liverpool awarded him the D Sc degree

In recent years, Redfearn's interests in ubiquinone and plastoquinone had widened into a general study of energy transductions in living systems This was stimulated partly by two extended periods of work with Dr Britton Chance at the Johnson Foundation of the University of Pennsylvania and one with Dr Tsoo E King at Oregon State University, and partly by his collaboration with a lively group of research students and postdoctoral fellows who were attracted to join him at Leicester Of particular note was the work which established rotenone as a specific inhibitor of mitochondrial NADH-oxidase, and the elegant elucidation of the two pathways by which electrons pass to separate terminal oxidases in *Azotobacter vinelandii* At the time of his death, Redfearn was turning his attention to photosynthetic bacteria, his most recent and uncompleted work provides evidence that the structure of chlorobium quinone requires to be modified

Eric Redfearn was a dedicated scientist, a loyal colleague and a delightful companion His untimely death will long remain a source of sorrow to all who were privileged to know him.

H L Kornberg

Dr H. M. Muir-Wood

Helen Marguerite Muir-Wood, for more than thirty years one of the leading authorities on the phylum Brachiopoda, died as the result of a stroke on January 16, little more than a month before her seventy-third birthday.

Born in Hampstead, north London, she took her first degree at Bedford College in 1918 and later studied under Professor E J Garwood at University College, London, where she developed an interest in Middle and Upper Palaeozoic rocks and their brachiopod faunas

In 1919 she was employed as a part-time curator in the department of geology (now the department of palaeontology), of the British Museum (Natural History), and the following year she accepted the position of assistant with full charge of the Brachiopod collections, a post she held, with appropriate promotions, until her retirement in 1965 at the age of seventy

During a full working life Helen Muir-Wood produced more than fifty memoirs and papers on all aspects of the Brachiopoda including a monograph on the Carboniferous Productoids and memoirs on the Jurassic and Palaeozoic faunas, not only of Great Britain, but of India, Sikkim, Malaya, Irak, Persia, Palestine and Somaliland She held office as a member of the Council of the Geological Society of London, the Palaeontographical Society, the Ray Society and the Systematics Association

Although her chief research interests included the morphology, systematics and evolution of the Lower Palaeozoic to Recent genera, she became particularly well known in the thirties for her pioneer work in establishing a classification of Mesozoic genera and species on their internal structures which were ascertained by transverse serial sections This technique, hitherto used only broadly by a few continental workers, provided the first major step forward in the understanding of the evolution and morphological variation of the group, replacing the somewhat arbitrary methods adopted by S S Buckman

Some of the early research work in connexion with her ideas on the classification was made possible by an award of the Lyell Fund which was presented to her by the Geological Society in 1930 On the completion of this work and in respect of her earlier publications, she received the degree of Doctor of Science from the University of London in 1934

During the Second World War, from 1942 to 1945, she served in the secretariat of the Admiralty at Bath and although this took her away for a time from her palaeontological researches, she managed to maintain an interest by collecting fossils from beds of the Great Oolite Series exposed in the Bath–Bristol district

After the war she returned to work at the British Museum (Natural History), continuing her researches on Middle and Upper Palaeozoic genera In 1950 she agreed to joint authorship, with Dr G A Cooper of the Smithsonian Institution, Washington, on a work exclusively on the Productoid genera and for this purpose visited the United States on two occasions The result of this collaboration appeared as "Morphology, classification and life habits of the Productoidea (Brachiopoda)" in 1960 and was quickly recognized by brachiopod workers as being one of the greatest contributions to the study of the phylum It was largely as a result of her researches in connexion with the publication that she was invited by the American editorial board to contribute, supervise and partly edit the Brachiopoda section for the *Treatise on Invertebrate Palaeontology* This tremendous undertaking required a concentration of both mental and physical resources second to none, but despite this she willingly accepted the additional post of deputy keeper of the department of palaeontology, British Museum (Natural History) in 1955, involving herself with a host of administrative problems which she discharged with consummate skill and her usual thoroughness This appointment, previously held only by a male member of the department, counted for more than a major triumph in her life, for her views were distinctly those of a feminist These views may have been strengthened by her early difficulties in establishing herself in what had always been a strictly masculine profession

In recognition of her services to geology, Helen Muir-Wood received the coveted distinction of the Lyell Medal which was presented to her by the Geological Society in 1958

Always sympathetic to the younger worker, Dr Muir-Wood will be remembered for her wise counsel by numerous enthusiastic research students, many now prominent names in this field of research themselves Aware of the many pitfalls associated with the systematics of the group, she was always keen to guide the unwary newcomer to safe ground with liberal understanding and kindness

Ellis Owen

University News

London

Dr J E Houldin, senior lecturer at Chelsea College of Science and Technology, has been appointed to the chair of electronics tenable at that college and Dr Richard Creese, reader at St Mary's Hospital Medical School, has been appointed to the chair of physiology tenable at that school The title of professor of bacteriology (infectious diseases) has been conferred on Mr D A Mitchison in respect of his post at the Royal Postgraduate Medical School

Nottingham

Dr J W. Barrett, research director of Monsanto Chemicals Ltd , has been appointed special professor of industrial chemistry, and Dr S Shone, senior administrative medical officer of the Sheffield Regional Hospital Board, has been appointed special professor of medical administration

Announcements

The Nuffield Foundation has awarded its first travelling fellowship in tropical marine biology to Dr E R Trueman, senior lecturer in zoology in the University of Hull He will work at the University of the West Indies, Jamaica, and intends to investigate aspects of the littoral and sublittoral fauna of the island

The Institute of Physics and the Physical Society have awarded the Maxwell Medal and Prize jointly to Professor K W H Stevens, professor of theoretical physics at the University of Nottingham, and Dr R J Elliott of the University of Oxford

The following medals were awarded at the spring meeting of the Optical Society of America the *David Richardson Medal* to Dr H E Edgerton of the Department of Electrical Engineering, Massachusetts Institute of Technology, the *1968 Adolph Lomb Medal* to Dr D C Sinclair of Spectra-Physics, Inc , Mountain View, California

Meetings

Electron Microprobe Analysis, July 31–August 2, Chicago (D R Beaman, The Dow Chemical Company, 241 Building, Midland, Michigan)

Progress in Overhead Lines and Cables for 220 kV and above, September 16–20, The Institution of Electrical Engineers (The Conference Department, The Institution of Electrical Engineers, Savoy Place, London, WC2)

Erratum In the announcement section of the March 23 issue of *Nature* (217, 1192, 1968) it was incorrectly stated that Professor W Morgan was director of the Lister Institute of Preventive Medicine The director is Sir Ashley Miles and Professor Morgan is deputy director

Erratum By an unfortunate misunderstanding in the *Nature* office, a number of references in the paper, "Late DNA Synthesis in Heterochromatin" by A Lima-de-Faria and Halina Jaworska (*Nature*, 217, 138, 1968), were incorrectly quoted The following changes should therefore be made Page 138, column 1, reference 1 should be 1–3, references 2, 3 should be 4, 5, column 2, references 4, 5 should be 6, reference 7 should be 7–11 Page 140, column 2, reference 43 should be 44, 45 In the first line of Table 2 on page 140, the references 4, 57 should in each case be replaced by 4, 5, 52 In Table 3 on the same page, reference 44 in the first line should be 45 and reference 69 should be 44 In the last line, the group of references 29–43 should be 29–31, 34–38, 40–43, in the same line, references 42, 43 and 70–72 should be 70, 71, 42, 43, 35 On page 141, column 1, the group of references given as 2, 52 should be 4, 5, 52 Lower down, reference 55 should be 55, 56 In column 2, reference 57 should be 57–59

CORRESPONDENCE

Cutting Cakes Blindfold

DEAR SIR,—I am surprised by your comments on the Science Research Council (*Nature*, 217, 991, 1968) Surely all those establishments outside the universities are overlooked, as indeed they always were, by boards and committees drawn both from the universities and from industry I do not see how their work would be improved, therefore, by "giving" them to the universities Neither am I prepared to suppose that because research is "university" research it is necessarily good research, this simply is not so Then again, a good deal of the cost to which you object will still be there whoever has these establishments, it is spent on buildings, electricity, administration, heating, wages, etc I would think that a good half of it must be spent in this way

And what do you propose for the staff, some of whom are first-rate men however much you may dislike what they are doing ? That they should join the brain-drain, or the unemployed ? Would it not be more intelligent to suggest that the distribution of these establishments is not all that it might be, and that they could be used by other departments, some of which are still expanding and needing staff ?

And what is "the common good", which the Radio and Space Research Station is apparently not concerned with ? In my understanding of the phrase, I do not include the spending of vast amounts of public money in discovering the "exciting new pulsations", an expenditure about to be greatly increased if I read the signs correctly The lot of 99 999 per cent of us would not change if all astronomy stopped to-morrow In any case, half the work of the station has to do, again as it always has, with propagation studies and the like a study which in most other countries has vastly more support than it has here, not less

Yours faithfully,
F V. BALE

The Coppice,
67 Switchback Road,
Maidenhead, Berks

Cows, Sheep, Pigs and Pounds

SIR,—You recently published a set of rules on the metrication of units (*Nature*, 217, 308, 1968) One was a reaffirmation of the convention that M means "multiply by a million" and m means "divide by a thousand" Although it was not explicitly stated, it also seemed that the convention that the number should precede the unit was being adhered to But your article on foot and mouth disease (*Nature*, 217, 1088, 1968) is in chaotic contravention The amount paid in compensation is given as £26 5 million Why not 26 5 M£ ? And the national herd is given as 12 342 m cattle, 28 885 m sheep and 7 107 m pigs Were they millipigs?

Until the end of the past century, a sum of money was usually specified by a number followed by an italic *l* Then the £ was introduced and its grandeur seems to have made people think that the frontal position was more suitable Why should we not, at any rate in scientific journals, use the same conventions when referring to pigs and pounds that we use when referring to grams and joules ?

Yours faithfully,
N W PIRIE

42 Leyton Road,
Harpenden

Orgueil Meteorite

SIR,—In relation to the letter "Occurrence of Olivine in a Type I Carbonaceous Meteorite" from J F Kerridge of this laboratory in your issue of February 24, 1968 (*Nature*, 217, 729, 1968), I would like to make some comments, particularly on his interpretation of his observations, with which I do not agree

I find it difficult to understand why the occurrence of olivine in a type I carbonaceous meteorite should have aroused scepticism This discovery is by no means a new one Olivine single crystals were reported and photographed in an optical microscope as long ago as 1962 by Professor G Mueller ("Interpretation of Microstructures in Carbonaceous Meteorites", *Nature*, 196, 929, 1962) The matter has also been referred to in another paper by Professor G Mueller and myself ("Significance of Inclusions in Carbonaceous Meteorites", *Nature*, 210, 151, 1966) and may be accepted as firm scientific knowledge

The Orgueil meteorite is extremely heterogeneous It still remains an unsolved problem how well crystallized olivine could co-exist with a low melting point carbonaceous phase The obvious solution is that the olivine crystals were formed first in the form of a high temperature dust, *nuéé ardente*, subsequently becoming incorporated in the stone, but the details of the process are not clear As to the composition of the olivine phase, the optical method is inadequate to determine it but the presence in almost every case of an iron-rich core supports Mr Kerridge's hypothesis that it is largely of the Fayalite type

In the 1966 paper referred to here, Professor Mueller and I pointed out that proof of a strict petrological character showed that these inclusions in various meteorites are fragments of meteorites of other types, particularly in the Sharps meteorite, indicating that all have the same parent body These views are quite compatible with the idea that the first stage of growth of the carbonaceous chondrites may have occurred from condensation of primary solar material

Yours sincerely,
J. D BERNAL

London, WC1

Electrophoresis for Free

SIR,—Your Molecular Biology correspondent (*Nature*, 217, 902, 1968) highlights the difficulties and errors in determining the sub-unit relationships of proteins, despite the use of sophisticated equipment and exemplary technique One little known technique with applications in this area is two dimensional electrophoresis (*Science*, 138, 152, 1962) Although not as precise as the ultracentrifuge, it can give useful results with heterogeneous preparations One may suppose that the reason this method is not more widely used is the unavailability of the equipment required Hence, the following offer is made to readers of *Nature*

For a limited period we will process protein samples and return a two dimensional pattern, with interpretation, gratis Samples should be accompanied by reference materials to bracket the postulated molecular weight, together with data on gross electrophoretic properties Protein concentration should be high enough to permit staining with amido black (ca 5 mg/ml)

We hope by this means to illustrate the value of this general technique, since it offers the possibility of obtaining valid data on the size–charge relationship of proteins with a minimal investment in both time and apparatus

Yours faithfully,
J BROOME

FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Monday, April 1

Institution of Electrical Engineers (at Savoy Place London WC2) Colloquium on "Injection Luminescence"

Institution of Mechanical Engineers, Medical Engineering Working Party (at 1 Birdcage Walk, Westminster, London, SW1), at 6 p m — Discussion Meeting on "Kidney Machines—Technical Medical and Social Problems"

Royal Society of Arts (at John Adam Street Adelphi, London, WC2) at 6 p m —"Industry and Commerce" (Last of three Cantor Lectures on "Modern China")

Society of Engineers (at the Geological Society Burlington House Piccadilly, London, W1), at 6 p m —Dr R Davies "High Speed Forming of Metals"

Society of Chemical Industry, London Section (at 14 Belgrave Square, London, SW1), at 6 30 p m —Dr N W Pirie FRS "The Use of Novel Proteins in Human Food"

Monday, April 1—Wednesday April 3

British Biophysical Society (at the University of Nottingham)—Meeting on "Biological Semiconductors"

Tuesday, April 2

Society of Chemical Industry, Pesticides Group—Physicochemical and Biophysical Panel (at 14 Belgrave Square, London, SW1), at 10 a m —Symposium on "Physicochemical Aspects of Penetration through Plant Cuticle"

Institution of Civil Engineers (at Great George Street, Westminster, London, SW1) at 5 30 p m —Informal Discussion on "Sludge Disposal" introduced by Mr P Coackley

Institution of Electrical Engineers (at Savoy Place, London, WC2), at 5 30 p m —Discussion Meeting on "Microwave Electrostatic Wattmeter" opened by Professor H E M Barlow

Institution of Electronic and Radio Engineers, Joint IERE/IEE Computer Groups (at the London School of Hygiene and Tropical Medicine Keppel Street, Gower Street, London, WC1), at 6 p m —Discussion Meeting on "Assessing Computer Performance"

Institution of Mechanical Engineers, Manipulative and Mechanical Handling Machinery Group (at 1 Birdcage Walk, Westminster, London, SW1), at 6 p m —Discussion Meeting on "Mechanical Handling of Freight Containers in Port Marshalling Yards"

Tuesday, April 2—Wednesday, April 3

Institute of Physics and the Physical Society, Materials and Testing Group (in conjunction with the National Physical Laboratory, at Teddington, Middlesex)—Conference on "Solid–Solid Interfaces"

Tuesday, April 2—Thursday, April 4

Faraday Society (at the University of Newcastle upon Tyne)—General Discussion on "Electrode Reactions of Organic Compounds"

Wednesday April 3

Colour Group (Great Britain) (at the Institute of Ophthalmology, Judd Street, London, WC1), at 2 30 p m —Meeting on "Colourvision" Dr R A Weale "Further Experiments on Human Vision Pigments"

Geological Society of London (at Burlington House, Piccadilly London, W1), at 5 p m —Dr P G Llewellyn and Mr R Stabbins "Core Material from the Anhydrite Series Carboniferous Limestone, Hathern Borehole, Leicestershire" (Demonstration), Mr D R C Kempe "The Kilonwa Syenite, Tanzania" (Paper), Dr C B Phipps and Dr F A E Reeve "Structural Geology of the Malvern, Abberley and Ledbury Hills" (Paper)

Royal Meteorological Society (at 49 Cromwell Road London, SW7), at 5 p m —Professor G W Platzman "The Rossby Wave" (Symons Memorial Lecture)

Society of Chemical Industry, Road and Building Materials Group (joint meeting with the Institution of Highway Engineers, at the Institution of Structural Engineers, Upper Belgrave Street, London, SW1), at 5 p m —Meeting on "Engineering and Related Properties of Pulverized Fuel Ash"

Royal Society of Medicine, History of Medicine Section at 1 Wimpole Street, London, W1), at 5 15 p m —Sir John Charles "Twenty Years of the World Health Organization"

Institute of Petroleum (at 61 New Cavendish Street London, W1), at 5 30 p m —Mr R A Vere "New Aviation Turbo-Fuel Specifications Adequately Control Fuel Quality"

Institution of Civil Engineers (at Great George Street, Westminster, London, SW1), at 5 30 p m —Informal Discussion on "Experience in the Implementation of Mechanized Maintenance of Track" introduced by Mr F J J Prior and Mr K W Pearce

Institution of Electrical Engineers (at Savoy Place, London, WC2) at 5 30 p m —Mr J Reeve "Logical Behaviour of H V D C Convertors During Normal and Abnormal Conditions and Direct Digital Protection"

Thursday, April 4

Society for Analytical Chemistry, Automatic Methods Group, and the Association of Clinical Biochemists (Southern Region) (in the Department of Electrical Engineering, Imperial College, London, SW7), at 9 30 a m —Lecture and Demonstration Meeting on "Newer Systems in Automatic Analysis"

Royal Society of Arts, Commonwealth Section (at John Adam Street, Adelphi, London, WC2), at 2 30 p m —Mr Malcolm Ford "New Zealand's Field Work in the Antarctic"

Royal Society (at 6 Carlton House Terrace, London, SW1), at 4 30 p m —Dr M A Grace FRS "The Alinement of Nuclei" (Review Lecture)

Institute of Mathematics and Its Applications (at the Royal Institution Albemarle Street, London W1), at 5 p m —Dr P G Wakely "Industry and the Mathematician" (Presidential Address) *

Institution of Electrical Engineers (at Savoy Place London WC2), at 5 45 p m —Lord Jackson of Burnley, FRS Fourteenth Graham Clark Lecture

Institute of Refrigeration (at the National College for Heating, Ventilating Refrigeration and Fan Engineering, Southwark Bridge Road London SE1), at 6 p m —Mr A R Went and Mr A P Ivers "Design and Operation Considerations—Insulated and Refrigerated Transport"

Institution of Mechanical Engineers Process Engineering Group (at 1 Birdcage Walk, Westminster London SW1) at 6 p m —Discussion Meeting on "An Approach to the Design of Half-Coil Pressure Vessels"

Thursday, April 4—Saturday, April 6

British Society for the History of Science (at Loughborough University of Technology, Loughborough)—Symposium on "The Teaching of the History of Science (In Schools and Colleges)"

Friday, April 5

Institution of Electrical Engineers (at Savoy Place, London, WC2), at 5 30 p m —Mr L C L Dale, Mr L B Knowles and Mr T H Morrison "Gas Turbine Plants for Peak Load Generation and Synchronous Compensation—a review of the Installations for the Central Electricity Generating Board"

Monday, April 8

Medical Research Council (at the National Institute for Medical Research, Mill Hill, London, NW7), at 4 30 p m —Professor A G Ogston, FRS (Australian National University, Canberra) "Some Aspects of Interactions Between Macromolecules"

Institution of Civil Engineers, Piling Committee (at Great George Street, Westminster, London, SW1), at 5 30 p m —Informal Discussion on "Use of *In situ* Diaphragms—Continuous Bored Pile—Slurry Trench—Thin Diaphragm"

Institution of Electrical Engineers (at Savoy Place, London, WC2), at 5 30 p m —Mr E A Lloyd "Eddy Currents and Automatic Inspection"

Monday, April 8—Tuesday, April 9

Biological Council (in the Edward Lewis Theatre, Middlesex Hospital Medical School, Cleveland Street, London, W1)—Symposium on "Scientific Basis of Drug Dependence".

Institution of Electronic and Radio Engineers, Institution of Electrical Engineers, Electronics Division, at Imperial College London, SW7) at 9 a m daily—Joint Conference on "Thick Film Technology"

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Lecturer (with a Ph D and able to give evidence of the ability to teach and conduct research in the field of rotating machines, with particular reference to their use in control systems) in Electrical Engineering—The Registrar, University College of Swansea, Singleton Park, Swansea, South Wales (April 8)

Visiting Lecturer in Chemistry at the University of Canterbury, Christchurch, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (April 8)

Lecturer (with interests in the following fields of specialization fluid mechanics, structural mechanical and computer systems, design synthesis, transportation engineering operation research and systems and geotechnical engineering) in Civil Engineering—The Registrar, University College of Swansea, Singleton Park Swansea, South Wales (April 11)

Professor (with a higher degree, preferably a doctorate, and research experience in the field of entomology) of Entomology at the University of Queensland, Australia—The Secretary-General, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (London and Brisbane, April 12)

Head of the Department of Biology—Clerk to the Governing Body, Paisley College of Technology, High Street, Paisley (April 15)

Lecturer or Assistant Lecturer (Probationary) (preferably with an interest in animal behaviour) in Zoology—The Secretary Bedford College (University of London), Regent's Park, London, NW1 (April 15)

Lecturer/Senior Demonstrator (with a higher degree in geology with particular interests in the fields of palaeontology and stratigraphy, and preferably some previous teaching experience) in Geology at the University College of Townsville, University of Queensland, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (Australia and London April 15)

Lecturer in Physics—The Secretary, Trinity College (University of Dublin), Dublin 2 Republic of Ireland (April 16)

Assistant Lecturer (preferably with a special interest in logic) in the Department of Philosophy—The Registrar, The University, Liverpool, quoting Ref RV/414 (April 17)

Professor, Senior Lecturers (2), and Lecturers (2) in the Department of Mathematics, University of Ife, Nigeria—The Inter-University Council, 33 Bedford Place, London, WC1 (April 23)

Chair of Archaeology of the Roman Provinces at the Institute of Archaeology—The Academic Registrar, University of London, Senate House, London, WC1 (April 25)

Lecturer in Zoology and Curator of the Zoological Collections (which do not include insects)—The Secretary of the Faculties, University Registry, Broad Street, Oxford (April 27)

Lecturer or Assistant Lecturer in Biology at the University of the West Indies, Barbados—The Inter-University Council, 33 Bedford Place, London, WC1 (April 29)

Lecturer in Organic Chemistry—The Secretary of the University Court, The University, Glasgow (April 30)

Lecturer/Senior Lecturer in Microbiology at Massey University, Palmerston North, New Zealand—The Secretary-General, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (New Zealand and London, April 30)

SENIOR LECTURER or LECTURER IN BIOCHEMISTRY at the University of Auckland, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (New Zealand and London, April 30)

SENIOR LECTURER or LECTURER IN BIOCHEMISTRY at Victoria University of Wellington, New Zealand—The Association of Commonwealth Universities (Branch Office) Marlborough House, Pall Mall, London, SW1 (New Zealand and London, April 30)

UNIVERSITY STUDENTSHIPS AND FELLOWSHIPS for experimental and theoretical research in nuclear and elementary particle physics and solid state physics and also for theoretical research in plasma physics—the Secretary to the University Court, The University, Glasgow (May 4)

LECTURER (with a special interest in mineralogy/petrology and prepared to lecture in palaeontology up to second year level) in GEOLOGY at Makerere University College, Uganda (University of East Africa)—The Inter-University Council, 33 Bedford Place, London, WC1 (May 7)

SENIOR LECTURER and LECTURERS (2) IN THE DEPARTMENT OF PHYSIOLOGY Makerere University College, Uganda (University of East Africa)—The Inter-University Council, 33 Bedford Place, London, WC1 (May 8)

SENIOR LECTURERS or LECTURERS (with qualifications in either pure or applied mathematics and preferably a qualification in algebra) in MATHEMATICS at the University of Canterbury, Christchurch, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (May 15)

RESEARCH ASSISTANTS (with, or expecting to obtain, a good honours degree in agricultural botany or botany) in the DEPARTMENT OF AGRICULTURAL BOTANY, for research in the field of genetics, crop physiology or plant pathology—The Secretary, University College of Wales Aberystwyth

RESEARCH ASSOCIATE ELECTRON MICROSCOPIST to join a Cell Research Group engaged in investigating the nature of the adhesive mechanisms at the cell surface—Professor B M Jones, Department of Zoology, University College of Wales, Aberystwyth

SENIOR LECTURER (preferably with experience or interest in the fields of mineralogy, petrology or geochemistry) in GEOLOGY—Clerk to the Governing Body, Northern Polytechnic, Holloway, London, N7

A new research microscope... the Standard RA

You'll never know ease of focusing until you turn the fine-focusing control on the "RA" It operates throughout the entire range of stage movement No backlash. No annoying stops.

We have added a large new rectangular base for solid stability. The new light grey finish is easier to clean, more corrosion-resistant. We couldn't improve the optics nor the silken ease of the mechanics, nor expand on interchangeability for which all Zeiss microscopes are noted. No one can So we have maintained them.

Full details from Carl Zeiss at
Degenhardt & Co Ltd.,
20/22 Mortimer Street,
London, W.1.

APPOINTMENTS VACANT

UNIVERSITY COLLEGE OF WALES

ABERYSTWYTH

DEPARTMENT OF AGRICULTURAL BOTANY

Applications are invited for the post of LECTURER/ASSISTANT LECTURER in the above Department, with a special interest in Genetics and Biological Statistics Postgraduate experience desirable

Application forms are obtainable from the Registrar to whom all applications should be sent by April 30, 1968 (1194)

UNIVERSITY OF LIVERPOOL

Applications are invited for the post of Assistant Lecturer or Lecturer at the Tidal Institute and Observatory, Bidston, Birkenhead, Cheshire

The successful candidate will be expected to engage in research in numerical analysis, with particular reference to tidal and other geophysical time series

Salaries will be within the range £1,105 to £1,340 per annum for an Assistant Lecturer and £1,470 to £2,630 per annum for a Lecturer

Applications stating age, qualifications and experience, together with the names of three referees, should be received not later than April 15, 1968, by the Registrar from whom further particulars may be obtained Please quote Ref RV/415/N (1202)

MEDICAL RESEARCH COUNCIL UNIT FOR METABOLIC STUDIES IN PSYCHIATRY

UNIVERSITY OF SHEFFIELD

PHYSIOLOGIST, preferably post-doctoral required to work on abnormal biological rhythms, or the application of bioassays of vasopressin, gonadotrophins or oestrogens, or related problems Excellent facilities

RESEARCH BIOCHEMIST with clinical interest required to work on adrenal thyroid, and/or pituitary function in patients with regularly recurring psychoses Excellent facilities

All enquiries to Professor F A Jenner Whitley Wood Clinic, Sheffield, S10 3TL (1198)

UNIVERSITY OF EAST AFRICA

MAKERERE UNIVERSITY COLLEGE UGANDA

Applications are invited for Lectureship in Department of Biochemistry, Faculty of Medicine Preference given to candidates with experience or interest in (a) teaching medical students and (b) biochemical research in relation to medical problems Salary £EA1 950 to £EA2 280 p a (one EA shilling = 1s 2d sterling) Salary supplemented in appropriate cases under British Expatriates Supplementation Scheme in range £345 to £410 per annum (sterling) F S S U Family passages, biennial overseas leave

Detailed applications (six copies) naming three referees, by May 2, 1968, to Inter-University Council 33 Bedford Place London, W C 1, from whom particulars may be obtained (1139)

RADIATION BIOLOGY AND CELLULAR KINETIC RESEARCH GROUP

Staff positions open in renal physiology cancer biology immunology and biochemistry

SCIENTISTS with significant post-doctoral experience are invited to submit curricula vitae to Samuel W Lesher, Ph D, Director Division Radiation Biology Department of Radiology Allegheny General Hospital 320 E North Avenue Pittsburgh, Pennsylvania 15212 (1022)

INTERNATIONAL COUNCIL OF SCIENTIFIC UNIONS

COMMITTEE ON DATA FOR SCIENCE AND TECHNOLOGY

SCIENTIFIC WRITER/EDITOR

Applications are invited from graduates (male or female) for the position of Scientific Writer/Editor on the small staff of the Central Office of the Committee on Data for Science and Technology (CODATA) of the International Council of Scientific Unions (ICSU), located in Frankfurt (Main), Germany Starting date as soon as possible Knowledge of German would be helpful but is not essential

The main task will be to prepare new editions of the *International Compendium of Numerical Data Projects* which includes a detailed description of the organization and activities of world wide numerical data centres and a review and analysis of their publications In addition the editor will be responsible for the publication of the CODATA Newsletter

This appointment would interest a science graduate with a sound chemical and/or physical background, together with the ability to present scientific information in clear concise English

Salary in the range of £2,000 to £2,700 per annum according to experience (plus fringe benefits) and with addition for Good Honours Degree

Applications, stating full details of age, qualifications, experience, present work and the names of two referees, should be sent to The Executive Secretary, The Royal Society, 6 Carlton House Terrace London, S W 1 by April 19, 1968 (1204)

UNIVERSITY OF OXFORD

DEPARTMENT OF BIOMATHEMATICS

Applications are invited for the post of Temporary Research Assistant to assist in a statistical research project supervised by the Professor of Biomathematics, to whom applications should be sent Degree in mathematics or similar professional qualification required Knowledge of statistics and/or computing an advantage Starting salary about £950 F S S U, subject to qualifications (1268)

UNIVERSITY OF OXFORD

INSTITUTE OF EXPERIMENTAL PSYCHOLOGY

An Electronic Specialist is required about June 1 1968, to direct design, development and maintenance of apparatus, and to take charge of a section of the Institute in a new building now under construction Candidates should have an appropriate University degree or equivalent professional qualification The salary will be on the Departmental Research Assistant scale £1 450 to £2 350 depending upon age and experience F S S U benefits

Please apply with details of career and names of two referees to the Administrator Institute of Experimental Psychology, 1 South Parks Road Oxford, as soon as possible (1148)

UNIVERSITY OF GLASGOW

WELLCOME LABORATORIES FOR EXPERIMENTAL PARASITOLOGY

Applications are invited for a Research Assistantship to work on the nutrition of tapeworms Appointment tenable for three years Initial salary up to £1,200 per annum with F S S U and annual increments of £100

Further particulars from Dr C A Hopkins University Veterinary Hospital, Bearsden Road Bearsden Glasgow to whom applications with the names of two referees, should be sent by April 30 1968 (1129)

CLINICAL CHEMIST, PH D FOR 800-BED teaching hospital of University of Toronto Responsibilities include sharing in supervision of modern routine and special procedures laboratories as well as method development Opportunity for post-doctoral training in clinical chemistry if necessary Write Dr A Rapoport Toronto Western Hospital 399 Bathurst Street, Toronto 2B Canada (1247)

UNIVERSITY OF LONDON INSTITUTE OF PSYCHIATRY

Research worker required with an interest in animal behaviour to work on the problems of communication within a primate group A background in zoology or physiological psychology or an interest in social organization would be an advantage Three-year appointment

Enquiries to Dr Richard P Michael, Primate Research Centre, Bethlem Royal Hospital Monks Orchard Road Beckenham, Kent Telephone 01-777 7887 (1206)

THE NORTH OF SCOTLAND COLLEGE OF AGRICULTURE AND DEPARTMENT OF AGRICULTURE, UNIVERSITY OF ABERDEEN

SCHOOL OF AGRICULTURE

Applications are invited for the post of HEAD OF THE CROP HUSBANDRY DIVISION with responsibilities for specialis[illegible] advisory work and College and University studies Salary scale Grade I, £2,651 to £3 345 per annum Superannuation scheme Medical examination

Further particulars, together with Forms of Application, and particulars of the appointment may be obtained from the Secretary, The North of Scotland College of Agriculture, 41½ Union Street, Aberdeen, AB9 1UD, with whom applications should be lodged not later than April 15 1968 (1245)

UNIVERSITY OF DURHAM

Applications are invited for the post of Research Assistant in Botany to work with Dr Margaret E Bradshaw on the population dynamics of selected species in Upper Teesdale The appointment will be for three years and will commence as soon after the closing date as possible The salary will be on the scale £850 to £950 with F S S U

Applications (3 copies) should be sent by Saturday April 13, 1968 to the Registrar and Secretary, Old Shire Hall, Durham from whom further particulars may be obtained (1236)

ROYAL UNIVERSITY OF MALTA

Applications are invited for a Lectureship in Biology The vacancy is for a Botanist Salar (including overseas allowance) £1,500 by £7 to £2 025 per annum F S S U Passages provided for appointee, wife and children under 1 years of age, up to a maximum of £75 per hea on appointment and normal termination Detailed applications (6 copies) naming thre referees by April 29, 1968, to Inter-Universit Council, 33 Bedford Place, London, W C 1, fro whom particulars are obtainable (1233)

UNIVERSITY OF THE WEST INDIES—TRINIDAD

Applications are invited for (a) Research Fellowship, or (b) Junior Research Fellowship i Faculty of Agriculture Candidates should hav a degree in agriculture agricultural science o equivalent qualification preferably with post graduate experience and experience of tropica soils and agriculture Appointee may be required to work in any of the islands served b the University Salary scales (a) £1 550 t £2 630 per annum, (b) £1,250 to £1,410 pe annum Child allowance F S S U Famil passages triennial study leave Detailed applications (6 copies) naming 3 referees should b sent by April 30, 1968, by persons living in th Americas and Caribbean area, to Secretary University of the West Indies, St Augustine Trinidad and by all others to Inter-Universit Council 33 Bedford Place, London, W C 1 Further particulars obtainable similarly (1232)

UNIVERSITY OF EAST AFRICA

MAKERERE UNIVERSITY COLLEGE—UGANDA

Applications are invited for Lectureship i Geology Candidates should have a speci interest in Mineralogy/Petrology and should als be prepared to lecture in Palaeontology up t second-year level An interest in Geochemistr would be of further advantage Salary scal £EA1,350 to £EA2,230 per annum (one E shilling equals 1/2d sterling) Salary supplemented in appropriate cases under British Expatr ates Supplementation Scheme in the range £34 to £410 per annum (sterling) F S S U Famil passages, biennial overseas leave Detailed appl cations (6 copies) naming 3 referees, by May 1968, to Inter-University Council, 33 Bedfor Place, London, W C 1, from whom particula are available (1231)

E.MERCK AG E Merck

Steroid Research

is of growing importance within our development programme We have made substantial progress and are seeking to extend our efforts in this field.

The Department of

Experimental Endocrinology

plays a vital part in this programme

We require a suitable person as

Head of Department

He should have experience in scientific teamwork, be conversant with the technique of screening and assessing steroid compounds also in methods used for developing new products

Whilst our Research Department is located in Germany, we would welcome a scientist with English as his mother tongue—the more so since E. Merck, Darmstadt is international Command of the German language would be useful (but is not essential)

Please write to us, even if your qualifications do not quite match this outline Scientific and human integrity apart, responsibility and initiative are our principal requirements

Salary and fringe benefits will be a matter for personal negotiation They will reflect the importance we place on this appointment

E. Merck Aktiengesellschaft, 61 Darmstadt/Germany

DIVISION OF ANIMAL HEALTH

GENERAL The Division of Animal Health of the Commonwealth Scientific and Industrial Research Organization has three major laboratories—the Animal Health Research Laboratory, Melbourne, the McMaster Laboratory, Sydney, and the Veterinary Parasitology Laboratory, Brisbane

The major areas of research at the Animal Health Research Laboratory, Parkville, Victoria, include bovine pleuropneumonia, virus diseases, tuberculosis, infectious bovine infertility, ovine footrot, parasitic diseases of sheep and cattle in the southern winter rainfall zone and investigations into plant poisons

It is proposed to set up a section for tuberculosis research at the Animal Health Research Laboratory, and applications are invited for appointment as Research Scientist to each of two positions

MICROBIOLOGIST—IMMUNOLOGIST

DUTIES The Division is expanding its programme of fundamental immunological research, particularly in those fields relevant to mycobacterial infections Work is already in progress with special reference to ruminant immune globulins including immediate-type hypersensitivity It is hoped that future work will widen and supplement these studies into areas of cellular immunology and delayed-type hypersensitivity

The Laboratory is well equipped for these studies and possesses an analytical ultracentrifuge, electron microscope, fractionation equipment, cold room and extensive small and large animal accommodation

QUALIFICATIONS Applicants should have a Ph D degree in Science or in Applied Science with emphasis on Biology, or postgraduate research experience of equivalent standard and duration, supported by satisfactory evidence of research ability

SALARY Depending upon qualifications and experience, the appointment will be made within the salary range of Principal Research Scientist, $A8,242–$A9,490 p a, or Senior Principal Research Scientist, $A9,918–$A10,230 p a Salary rates for women are $A428 p a less than the corresponding rates for men

VETERINARIAN

DUTIES The appointee will be required to collaborate in the immunological research on bovine tuberculosis, particularly in the applied aspects of the programme He may be required to study the epidemiological aspects He would liaise with the meat inspection services, with the State veterinary services and with the Northern Territory Administration

QUALIFICATIONS Applicants should have a degree in Veterinary Science and a Ph D degree in a relevant discipline, or post-graduate research experience of equivalent standard and duration, supported by satisfactory evidence of research ability

SALARY Depending upon qualifications and experience, the appointment will be made within the salary ranges of Research Scientist, $A5,250–$A6,622 p a or Senior Research Scientist, $A6,892–$A7,974 p a Salary rates for women are $A428 p a less than the corresponding rates for men

CONDITIONS The appointments, which carry Commonwealth Superannuation Fund or Provident Account privileges, will be conditional upon passing a medical examination An initial probationary period of 12 months may be specified

Consideration would be given to appointment for an initial period of three years at the conclusion of which an extension of tenure or appointment for an indefinite period would be considered

Applications, quoting Appointment No 201/301 (Microbiologist-Immunologist) or 201/302 (Veterinarian), and stating full name, place, date and year of birth, nationality, marital status, present employment, details of qualifications and experience, together with the names of not more than four persons acquainted with the applicant s academic and professional standing, should reach

Mr R F Turnbull,
Chief Scientific Liaison Officer,
Australian Scientific Liaison Office,
Africa House, Kingsway,
London, W C 2, by the **24th May, 1968** (1259)

UNIVERSITY COLLEGE OF NORTH WALES

MATERIALS SCIENCE

SCHOOL OF ENGINEERING SCIENCE

Opportunities for research leading to the degree of Ph D are available in the Division of Materials Science which has a special interest in the electronic properties of materials Research in progress is linked whenever possible, with industrial laboratories and includes studies of

Atomic structure of metal surfaces and interfaces
Single crystal whisker growth and evaluation
Epitaxy and trace contamination in semiconductors
Local conduction in oxide and organic polymer films
Ultra-high vacuum preparation and assessment of semiconductor thin films
Conduction in liquid dielectrics and construction of liquid electrostatic devices
Emission mechanisms and motion of high current discharges

Excellent facilities are available, especially for surface and thin film studies, and include Scanning and Transmission Electron Microscopes, Field Emission and Field Ion-Microscopes, a Microprobe, X-ray Diffraction Equipment, an Infra-red Spectrometer and Ultra-high Vacuum facilities

A full programme of lectures forming part of an M Sc Course on Electronic Materials and Devices is available to all research workers

Further particulars and application forms may be obtained from the Registrar, U C N W, Bangor (1241)

THE UNIVERSITY OF MANCHESTER
MANCHESTER, 13

ASSISTANT LECTURER IN PHYSICS

Applications invited for above post associated with Low Temperature group under Professor H E Hall The research interests of the group are liquid helium and the transport properties of superconductors Candidates intending to pursue research in superconductivity preferred Salary range £1,105 to £1,340 per annum F S S U Particulars and application forms (returnable by May 10) from the Registrar Quote ref 41/68/Na (1240)

UNIVERSITY COLLEGE OF WALES

ABERYSTWYTH

DEPARTMENT OF AGRICULTURAL BOTANY

Applications are invited for RESEARCH ASSISTANTSHIPS in the field of Genetics Crop Physiology or Plant Pathology Applicants should have or expect to obtain a good honours degree in Agricultural Botany or Botany Permission to register for a higher degree will be granted in suitable cases (1239)

UNIVERSITY OF CAMBRIDGE

HISTOLOGIST (Technical Assistant £828 to £1 160) wanted for work on nervous and reproductive systems of birds and mammals Suitable applicant might occupy modern house adjoining laboratories in return for light caretaking duties

Apply, naming two referees, to Dr P Bateson Sub-Department of Animal Behaviour Madingley Cambridge (1267)

SCIENTIFICALLY QUALIFIED BACTERIOlogical assistant required in the Enteric Reference Laboratory to work with Dr E S Anderson, F R S Degree should be preferably in a biological subject The work is mainly con[illegible] with transferable drug resistance in the Enterobacteria —Applications with full details of age, qualifications and experience should be sent to Personnel Officer, Central Public Health Laboratory, Colindale Avenue N W 9 (1218)
